Raphael, who had been greatly favoured by Julius, became a personal favourite of Leo, who selected him to succeed Bramante as architect of St Peter's in 1514, and afterwards made him inspector of Roman ruins. But he was as impatient as his predecessor to get the Vatican chambers finished, and he successfully obtained from the masters the frescoes of the Camera dell'Incendio, which all illustrate scenes from the lives of Leonine popes: the Fire of Borgo, in which all the remnants of Roman buildings known to Raphael are introduced, the Battle of Ostia against the Saracens, the Coronation of Charlemagne, and the Oath of Leo III. But Raphael was now too busy to attend personally to wall-painting, and much of his attention was taken up with the composition of the cartoons which he executed, with help from assistants, for the tapestries of the Sixtine Chapel. It would be impossible to describe these masterpieces or the tapestries made from them in the space here at

our command. The cartoons may be seen at the Kensington Museum, the tapestries at the Vatican. They are masterpieces worthy of a pilgrimage; the first completed in December 1516, the second woven at Brussels in 1519. At this period of his career Raphael was a welcome guest in the best circles of Rome, painted the likenesses of the pope's relatives, Giuliano and Lorenzo de' Medici, and was asked in vain for pictures by the Duke of Ferrara. His portraits of the Duke of Urbino, Castiglione, Bembo, Navagero, and his decoration of Cardinal Bibbiena's rooms at the Vatican tell of the company which he frequented. When Leo X. succumbed to Francis I. after Maignano Raphael followed the pontiff to Florence and Bologna, and found there the new patrons for whom he executed the Sixtine Madonna, the St Cecilia of Bologna, and the Ezekiel of the Pitti. The labours subsequently completed were immense, including the Spasimo at Madrid, the Holy Family and St Michael, which the pope sent to the king of France in 1518, and the likeness of the vice-queen of Aragon, followed by the celebrated portrait of the Violin player of the Sciarra collection at Rome. Wall-painting, with help from the assistants, was diligently carried on, and produced the cycle of the Psyche legend at the Farnesina, the gospel-scenes of the Loggia of the Vatican, and the frescoes of the Hall of Constantine. The last work done in the master's painting-room was the Transfiguration, which was nearly finished when Raphael died of a pernicious fever caught in the excavations of Rome. He expired on the 6th of April 1520, after a week's illness.

See, besides Vasari's, books by Castiglione (1766), Pungilioni (1822), Rumohr (1827), Passavant (1860), Campori (1870), Muntz (1881), Crowe and Cavalcaselle (1882), Springer (1883), Grimm (1886, trans. 1889), Lutzow (1890), Knackfuss (1895), Strachey (1900), Staley (1904), Cartwright (1914), McCardy (1917), Lavery (1920); and works on Italian painters by Morelli (1893), Berenson (1897).

Raphania, or **ERGOTISM**, is a disease which was much more prevalent some centuries ago than it is at present. The name *raphania* was first given to it by Linnæus, who thought the morbid symptoms were dependent upon the mixture of *Raphanus Raphanistrum*, or jointed charlock, with the wheat used as food. It was suspected, as early as the end of the 16th century, that the disease was due to the development of a fungus (*Claviceps purpurea*) in the grain, and this fact is now established, although some writers held (as Linnæus did) that this morbid state was also produced by the presence of poisonous plants, especially *Lolium temulentum*, or darnel, among the grain. Deficiency of proper food probably contributed to cause the disease, but it can be experimentally produced in animals by excessive doses of ergot alone. Although rye is the ordinary seat of the poisonous fungus, other grains are liable to be similarly affected, and to produce similar results. See **ERGOT**.

There are two forms of the disease—the spasmodic and the gangrenous. In both, symptoms of irritation of the digestive organs are the first to appear. In the spasmodic form tingling or itching of various parts of the body, with loss of sensation in the feet and hands, are the most constant symptoms. Violent contractions of the muscles may occur, giving rise to intense pain, and sometimes convulsions supervene. In the gangrenous form the extremities are painful, red but cold, and not easily moved; and after a varying time gangrene, due to spasm of the arteries, supervenes. With regard to treatment, the main thing is to replace the poisonous flour by easily digested,

wholesome food. Whatever be the form of treatment adopted, the mortality in the gangrenous form is usually very high.

Raphia, a genus of Palms (q.v.), the leaves, bark, and pith of which are used for various purposes. The bast of one South American species, *R. tedigera* or Jupati-palm, is largely used by gardeners everywhere for tying up plants, in fastening grafts, &c. And the midribs of the leaves of another species, found in Madagascar, &c., are supposed to have been taken for the feathers of the fabled Roc (q.v.). *R. rinifera* is the wine-palm of the Amazon.

Raphoe, a market-town of Donegal, 15 miles SSW. of Londonderry. Its former see was united to Derry in 1835. Pop. 700.

Rapidan, a river of Virginia, and tributary of the Rappahannock (q.v.).

Rapids. See WATERFALL, RIVER, NIAGARA, NILE, PARANA, &c.

Rapier, a light, highly-tempered, edgeless, thrusting weapon, finely pointed, and about 3 feet in length. It was for long the favourite weapon in duelling, and was won by every gentleman. At present it is worn only on occasions of court ceremonial. See FENCING, SWORD.

Rapin de Thoyras, PAUL DE, a French historian of England, was descended from a Protestant Savoyard family, which settled in France in the 16th century, and was born at Castres, in Languedoc, 25th March 1661. He studied at the Protestant college at Saumur, and passed as advocate in 1679, but had no liking for the profession; and when the revocation of the Edict of Nantes (1685) forced him to leave France he sought employment without success in England, and afterwards in Holland, where he enlisted in a corps of volunteers at Utrecht, formed by his cousin-german, Daniel de Rapin. With his company he followed the Prince of Orange to England in 1688, was made ensign in the following year, and distinguished himself by his bravery at the siege of Carrickfergus, the battle of the Boyne, and the siege of Limerick, where he was shot through the shoulder by a musket-ball. From 1693, tutor to the Earl of Portland's son, he travelled in Holland, Germany, and Italy, after which he settled first at The Hague, then in 1707 at Wesel, where he devoted the remaining seventeen years of his life to the composition of his great work. The severity of his labours is believed to have shortened his days. He died May 16, 1725. Rapin's *Histoire d'Angleterre* was published at the Hague in 8 vols. the year before his death. It was undoubtedly, as Voltaire has said, the best work on English history that had until then appeared; full, minute, careful in the citation of authorities, clear, rapid, and accurate in narration, methodical in the arrangement of its materials, comparatively impartial in spirit, and yet betraying on the part of the author an honourable reverence for law and liberty.

Rapin begins with the invasion of Britain by the Romans, and ends with the accession of William III. The work was continued to the death of William III. by David Durant (Hague, 2 vols. 1734). The best edition of the *Histoire* in its augmented form is by Lefebvre de Saint-Marc (Hague, 16 vols. 1749 *et seq.*). The original was translated into English by the Rev. Nicholas Tindal (Lond. 15 vols. 1725-31), and subsequently by John Kelly (in 2 vols. fol.).

Rapp, GEORGE, founder of the sect of Harmonists, was born in Württemberg in 1770, and, after an attempt to restore the church of New Testament days in Germany, emigrated with his followers to Western Pennsylvania in 1803. There he established a settlement which he named

Harmony (whence the early title of the sect, Harmonists or Harmonites). In 1815 the community removed to Ludiana, and founded New Harmony (q.v.); but this was sold in 1824 to Robert Owen, and Rapp and his followers returned to Pennsylvania, where they built Economy, a village on the right bank of the Ohio, 15 miles NW. of Pittsburg, and engaged in farming. There Rapp died, 7th August 1847. Impressed with the certainty of the speedy second coming of Christ, his absorbing aim was to amass great wealth, to be placed then at the Lord's disposal. To this end he and his followers practised a rigid economy, and lived a life of toil and self-denial, in which celibacy formed a part; and, with the same object, all things were held in common. As the years passed, the community became very wealthy, owning great farms, dairies, and vineyards. Its numbers, however, diminished, and it was all but extinct by the first decade of the 20th century.

Rapp, JEAN, COUNT, a French general, was born at Colmar, 27th April 1772. He was intended for the church, but his taste for a military life led him to enrol himself (1788) in the mounted 'chasseurs' of the French army. Distinguishing himself in Germany and Egypt, on the death of Desaix at Marengo Rapp became aide-de-camp to Napoleon. His brilliant charge at Austerlitz upon the Russian Imperial Guard was rewarded with the grade of general of division (1805). For his services at Lobau he was named a Count of the Empire (1809). He opposed the Russian expedition, but accompanied the Emperor throughout the whole of it, and defended Danzig for nearly a year against a powerful Russian army. The Russians, contrary to the articles of capitulation, sent Rapp and his garrison prisoners to Russia, and he did not return to France till July 1814. On reaching Paris he was well received by Louis XVIII.; but in 1815 he went over to his old master, and was appointed commander-in-chief of the army of the Rhine, and peer of France. After Waterloo Rapp again submitted to Louis. Re-created a peer of France (1819), he held various offices about the court, and died at Paris, 8th November 1821. See his *Memoirs* (1823), and Spach's *Biographies Alsaciennes* (1871).

Rappahannock, a river of Virginia, rises in the Blue Ridge of the Alleghany Mountains, receives the Rapidan (above this point it is sometimes called the North Fork), and flows about 125 miles south-east to Chesapeake Bay. It is tidal and navigable to Fredericksburg. The Rappahannock and the Rapidan were the scenes of some of the bloodiest battles of the Civil War, at Fredericksburg, Chancellorsville, and the Wilderness.

Rappee' (Fr. *rapé*), a coarse kind of snuff. See TOBACCO.

Rapperswyl, on the north shore of the Lake of Zurich, has an old castle fitted up in 1869 by a Polish nobleman as a Polish National Museum.

Rarey. See HORSE.

Rarotonga. See COOK ISLANDS.

Ras (= Heb. *rosh*), an Arabic word, signifying 'head,' 'promontory,' occurs in the names of many capes on the Arabian and North African coasts, and also in Sicily and Malta.

Rashes, affections of the skin, characterised by a red superficial efflorescence, diffused or in patches, disappearing under pressure, and usually ending in desquamation. To this division of cutaneous disorders belong Measles, Scarletina (or Scarlet Fever), Erysipelas, Erythema, Roseola (or Scarlet Rash), and Nettlerash. Of these rashes Measles, Scarletina, and Erysipelas are rather to be regarded as fevers or infectious dis-

than as cutaneous diseases in the true sense of the phrase.

Rashi (i.e. Rabbi Solomon bar Isaac, from the initials of Rabbi Shielomo Yizhaki, often erroneously called Yarchi through confusion with Solomon of Lunel. *Yarchi* means 'lunar', hence it became an equivalent of Lunel), the greatest Jewish commentator and exegete, was born about 1040 at Troyes, in France. The story of his extensive travels is legendary, but interesting; his tours, undertaken for purposes of study, were probably confined to Lorraine. At Worms, the 'Rashi Chapel' where he worked (c. 1055) still exists. He returned to Troyes (c. 1065) and remained there, acting as unpaid rabbi and judge, and acquiring great renown. He had no sons, but his three daughters, who were possessed of considerable scholarship, carried on his tradition. Their husbands were distinguished among Rashi's pupils, and they continued the school which he created. Rashi died at Troyes on 13th July 1105, saddened by the events of the first crusade. His fame rests mainly on his commentaries on the Bible and Talmud. That on the Pentateuch was the first dated Hebrew book to be printed (Reggio, 1475, without biblical text). The Bible Commentary (translated into Latin by J. F. Breithaupt, Gotha, 1710) exercised a great influence on Nicholas de Lyra, and, through him, on the Reformation (*Si Lyra non Lyrasset, Luther non Saltasset*). The Pentateuchal books have been rendered into German by L. Dukes (Prague, 1838), J. Dessauer (with text of Rashi vocalised and in square characters), and others, and have been the theme of many super-commentaries. A critical edition was published by A. Berliner (2d ed. Berlin, 1905). Rashi's Talmud Commentary is of such value that it is always printed with the Talmud. Parts were revised by his pupils and followers (the Tosafists), whose *Addenda* always appear in a parallel column. Rashi wrote various other works, including *Responsa* and liturgical treatises. One of the latter, *Sefer ha-Pardes*, has been re-edited by H. L. Ehrenreich (Budapest, 1924) from the Constantinople edition of 1567. Rashi is noted for his terseness and simplicity. His interests were wide, but he was not a philosopher like Maimonides. He was a good grammarian, but inferior to Qimhi. Though his method was somewhat unscientific at times, his learning was always profound. Frequently he reproduces in Hebrew characters the vernacular equivalent of a word under discussion, and such glosses (*Latazin*) are of great value for Romance phonetics. Many have been edited by A. Darmsteter (*On the Pent.*, Paris, 1909), Brandin, D. S. Blondheim (*Les Parlers Judéo-Romans* [the bibliography should be consulted], Paris, 1926), etc.

BIBLIOGRAPHY.—See art. in *Jew. Encyc.* and bibliog. there given. See also M. Liber's *Rashi* (a concise Eng. biog. with bibliography), in 'Jew. Worthies Series' (Lond. and Phil. 1906); L. H. Weiss in *Bet-Talmud*, ii. 2-10 (Vienna, 1882); S. A. Hirsch, pp. 139-166 of *The Cabalists and other Essays* (Lond. 1922); I. Abrahams, ch. ix. of *Short Hist. of Jew. Lit.* (Lond. 1906); W. O. E. Osterley and O. H. Box, *Short Survey of Lit. of Jud.* (Lond. 1920); A. Berliner, *Beiträge z. Gesch. d. Raschi-Commentare* (Berl. 1903), contains much valuable information; to students beginning Rabbinics, J. H. Lowe's critical analysis and dissected translation of the first half of the commentary on Genesis (Lond. 1926-27), with full notes, will be found indispensable.

Rask. RASMUS CHRISTIAN, philologist, was born at Brandekilde, near Odense, in the island of Funen, 22d November 1787, studied at Copenhagen, and in 1808 published his first work on the rules of the Icelandic language. Appointed sub-librarian to the university, he drew up during the years 1807-12 grammatical systems for most of the

Germanic, Slavonic, and Romance tongues, comparing them with those of India. He then visited Sweden and Iceland, returning in 1816 to Copenhagen. In 1818 were published his splendid researches concerning the origin of the Icelandic language. He published in Stockholm (1817) his admirable Anglo-Saxon grammar and the first critical edition of the *Snorra Edda* and the *Edda Saemundar*. Going to St Petersburg, he there devoted himself for two years to the study of the oriental languages, principally Sanskrit, Persian, and Arabic, acquiring also a competent knowledge of Russian and Finnish. Thus equipped, he proceeded to Astrakhan, and then journeyed in the country of the Turkomans, the Caucasus, Persia (adding meanwhile the Mongol and Manchu dialects to his already enormous linguistic acquisitions), and finally Ceylon, where he acquainted himself with Singalese and Pali, and wrote his *Singalesisk Skriftelevre* (1822). In 1823 Rask returned to Copenhagen, laden with learning and rare manuscript treasures, of which the greatest part was presented to the university. In 1825 he was appointed professor of Literary History, in 1828 of Oriental Languages, and in 1831 of Icelandic. He died, exhausted by his immense labours, 14th November 1832, at the early age of forty-five. Rask also wrote on Frisian grammar (1825), on ancient Egyptian (1827), and Hebrew chronology (1828), grammars of several languages, and a great number of miscellaneous articles in the learned journals of the North, which were collected after his death, and published (3 vols. 1834-38). There are English editions of his Anglo-Saxon, Danish, and Icelandic grammars. See the *Lives* by Petersen (1870) and Rönning (1887).

Raskolniks, the name of a variety of sects in the Russian Church. See RUSSIA.

Raspail, FRANÇOIS VINCENT (1794-1878), a French chemist, doctor, and revolutionist, whose camphor-system (1845) was a forerunner of antiseptic surgery. See a monograph on him by Saint-Martin (Paris, 1877).

Raspberry (*Rubus Idaeus*), the most valued of all the species of *Rubus* (q.v.). The characters of the leaves, flowers, and fruit of raspberry are well

Raspberry (*Rubus Idaeus*).

illustrated in the accompanying figure. The wild raspberry has scarlet fruit, and is found in thickets and woods throughout the whole of Europe and the north of Asia. It is common in Britain. The raspberry has long been in cultivation for its fruit. There are many cultivated varieties, with red, yellow, and white fruit, much exceeding the wild kind in size. The root is creeping, perennial; the stems only biennial, bearing fruit in the second year, woody, but with very large pith. Planta-

tions of raspberries are most easily made by means of suckers. The raspberry loves a light rich soil, and is rather partial to a shady situation. The tall kinds are unsuitable in situations much exposed to winds, as the stems are easily broken. The rows are generally about 4 feet apart, the plants 3 to 4 feet apart in the rows. The young stems are thinned out to allow free access of air to those that are left. Stakes are often used to support the stems, or they are variously tied together. One of the most dangerous diseases is caused by the fungus *Didymella applanata*, which causes the bark to come off in long strips. A prophylactic treatment consists in spraying healthy plants with a 1 per cent. solution of solbar or copper-lime. Raspberries, fermented either alone or along with currants and cherries, yield a strong and very agreeable wine, from which a very powerful spirit can be made. Some of the other species of *Rubus* most nearly resembling the raspberry produce also agreeable fruits. *R. odoratus* is a highly ornamental shrub, a native of Canada and the northern states of America, is frequent in gardens in Europe and America, but rarely produces fruit in Britain.

Raspberry Jam, a name given to the West Australian *Acacia acuminata*, a tree with a fairly heavy wood with a remarkable scent resembling that of pressed raspberries. The grain is very beautiful, and it is therefore much prized for cabinet-work.

Raspe, R. E. See MÜNCHHAUSEN.

Rasputin, GREGORY EPIMOVITCH (1871-1915), Russian religious fanatic, born of a poor peasant family in the Siberian province of Tobolsk. After thirty years of dissolute living he suddenly underwent conversion, accounted himself an emissary from God, and became a monk. Diffusing a gospel that smiled on licence and orgy, Rasputin soon preached his way high into Russian society, and, by his arduous and wonderful powers, established himself a favourite of the empress. Meanwhile his influence waxed great, and his casually friends were given high appointments. But his enemies closed upon him, and, after two unsuccessful attempts to kill him, they laid him low with a treacherous bullet in December 1915.

Rassam, HORMUZD (1826-1910), Assyriologist, was born, the son of Chaldean Christian parents, at Mosul. He gained the friendship of Layard, and assisted him in his excavations at Nineveh in 1845-47 and 1849-51, and then succeeded him, until 1854, as British agent for conducting Assyrian explorations. His grandest success was the finding of the palace of Assurbanipal (Sardanapalus). After holding in the following years political offices at Aden and Muscat, he was sent (1864) by the British government to Abyssinia to demand the release of the Europeans kept in prison by King Theodore; but that potentate cast him also into prison, and he was only released with the rest of the captives after the army had been defeated by Sir R. Napier in 1868. From 1876 to 1882 Rassam was employed by the trustees of the British Museum in making explorations in Mesopotamia, and discovered Sippara and Kuthah. He published *The British Mission to Theodore, King of Abyssinia* (1869).

Rastatt, or RASTATT, a town in Baden, stands on the Murr, 3 miles from its junction with the Rhine, and 15 miles SW. of Karlsruhe. It has steel manufactures. From 1725 to 1771 the town was the residence of the Margraves of Baden-Baden. Fortifications were erected in 1840-48 by Austrian engineers to protect the northern entrance to the Black Forest. Rastatt is memorable for two congresses—the first in 1714, when a treaty which ended the war of the Spanish Succession was signed

between Villars and Prince Eugene; and the second in 1797-99. On the breaking up of this latter congress without any definite result the three French plenipotentiaries set out for Strasburg; but they had scarcely got beyond the gates of Rastatt when they were attacked by Austrian hussars, and two of the three slain, whilst the third was left for dead in a ditch. Their papers were carried off, but no further spoil was taken. The town played a prominent part in 1849 as the stronghold of the revolutionists in Baden. Pop. 12,000.

Rat, a name applied to the larger species of the rodent genus *Mus*, e.g. to the two species occurring in Britain, the Brown Rat (*M. decumanus*) and the Black Rat (*M. rattus*). Like mice, which belong to the same genus, rats are agile, alert, and graceful animals, of catholic appetite, and prodigious fertility. In habit they are predominantly nocturnal. The bright eyes, prominent ears, naked muzzle, soft fur, and long scaly tail are familiar external characteristics. The so-called water-rat is a very different kind of animal, a vole, in the genus *Microtus*. Most 'Black Rats' are brown and many 'Brown Rats' are black, but the two species are quite distinct. The Black Rat is smaller, smarter, and lighter, with a sharper muzzle, and larger, almost naked, ears, with a slender tail at least as long as the head and body combined, with relatively large pads on the soles of the feet, and with more numerous harsh hairs in the fur. The Brown Rat is larger, heavier, and more robust, with a blue muzzle and shorter hairy ears, with a stout tail never so long as head and body combined, with relatively small pads on the soles of the feet, and with softer fur. There are also technical differences in the skull and differences in habit. The Black Rat is primarily an arboreal climbing animal; it rarely burrows; it does not

Black Rat (*Mus rattus*); Brown Rat (*Mus decumanus*).

like water or damp places. It usually enters ships by climbing along the cables, and is hardly to be balked except by metal shields. The Brown Rat also climbs well, but is given to burrowing and is fond of water. It infests sewers and drains, and tries all sorts of habitats from haystacks to coal-mines. It is more adaptable, inquisitive, and aggressive than the Black Rat, also more voracious and cunning. The White Rat is an albino form of the Brown Rat, as all its structural details, including the form of the blood-crystals, incontrovertibly prove. Both species of rat are aliens, hailing from the East. The Black Rat, which probably had its original headquarters in India, seems to have been introduced into Western Europe by the ships of the Crusaders. The Brown Rat, also Oriental, arrived in Europe in the early 18th century, and, as it increased, its predecessor decreased. In the *Origin of Species* Darwin instanced the case of the two species of rat as an illustration of competition being most severe between closely related

forms, and it is true that for a time after the middle of the 19th century the Black Rat was very rare in Britain, except in or near shipping ports, where there was continual fresh immigration. Now, however, the Black Rat is quite common again, and, although the two species sometimes fight to the death, it is probable that there were other reasons for the decline of the first comer. Houses began to be built more carefully, drains and sewers multiplied, man became less tolerant of house rats; the rougher, tougher, bolder, more ferocious species survived where the other went to the wall, but hardly as the result of combative competition. While predominantly vegetarian, and grain-eaters by preference, rats will devour almost anything from eggs to the feet of captive elephants, from young rabbits to fish offal. It is often related that in a slaughter-house near Paris, thirty-five dead horses were picked to the bones by rats in a single night; and it is known that around one sugar factory in Java between 9000 and 12,000 rats were killed every day for several years. Much damage is also done by gnawing through obstacles, even cement, brick, and lead being attacked by the strong, chisel-edged teeth. The material thus gonged away does not pass beyond the front of the mouth. Cannibalism is not unknown, and starving rats have been known to attack sleeping children and even a wide-awake man.

The destructiveness of rats is the more serious because of the prolific multiplication. They may breed at any time of year; a female under eighteen months old (when she usually ceases to bear) may easily have six litters in the twelve months; the young are carried by the mother before birth for only about three weeks; there are often eight young ones in a litter; the offspring are ready to breed when about four months old. Mr Hinton calculated that the 10 million pairs of breeding rats in Britain on 1st January 1918 would be represented at the end of the year by over 40 million pairs of breeding age, allowing for a mortality of 95 per cent. ! Such a rat population would mean in 1919 a consumption of nine million pounds' worth of food. The annual damage to grain-stuffs alone in the United States is estimated at over 100 million dollars. Moreover, it has to be remembered that rats harbour the bacillus of bubonic plague and spread typhus and other diseases. Combative measures are urgently needed: (a) more careful treatment of all sorts of crumbs and refuse; (b) the protection of natural enemies, such as stoats and weasels, owls and kestrels; (c) concerted trapping, poisoning, and fumigation; and (d) the careful use of virus. See most conveniently M. A. C. Hinton, *Rats and Mice as Enemies of Mankind*, British Museum, 1918.

Rata (*Metrosideros robusta*), a New Zealand tree growing especially in North Island related to various species of Ironwood (q.v.). The seed germinates in the branch of another tree, borne thither by the wind, and throws down vines which take root in the ground, and grow up around the supporting tree, eventually stifling it. The rata, now strong enough to support itself, grows on as an independent tree to a height of about 100 feet. The wood is very hard, formerly much used for making clubs, and is valuable for many purposes, though mainly used at present as fuel. Other species, *M. lucida* and *M. tomentosa*, are remarkable for their flowers and foliage.

Ratania, a flavouring essence made with the essential Oil of Almonds (q.v.). The name is sometimes given to other essences.

Ratak. See MARSHALL ISLANDS.

Ratcliffe Tables. See FRIENDLY SOCIETIES.

Ratel (*Mellivora*), a genus of quadrupeds of

the Bear group (Arctoidea), nearly allied to the Gluttons (q.v.), from which it differs in having one premaxillary less in each jaw and the upper tubercular teeth slightly developed. The general aspect is similar to that of the badgers, but heavier and more clumsy. Three species are known, which inhabit Africa and India; one species, the Cape Ratel (*M. ratel* or *capensis*), inhabits the south of

The Cape Ratel (*Mellivora capensis*).

Africa, and is said to feed much on bees and their honey, its thick fur protecting it against their stings; another inhabits the north of India, prowls about by night, is a voracious devourer of animal food, and often scratches up recently interred bodies from their graves. The Cape ratel is about the size of a badger, gray above, black below. It is easily tamed, and is amusingly active in confinement, continually running about its cage, and tumbling strange somersaults to attract the attention of spectators, from which it seems to derive great pleasure.

Rates.—A rate is a charge levied on an occupier of property for local purposes. The procedure for rating in England and Wales has been radically altered by the Rating and Valuation Act of 1925, which comes into operation on the 1st April, 1927: the new valuation lists to be made will probably be effective on 1st April 1928 or 1929, and will normally be reviewed every five years thereafter. Till then, by the Poor Relief Act of 1601, overseers in England and Wales are empowered to raise money 'by taxation of every inhabitant, parson, vicar, and every occupier of lands, houses, tithes, impropriate and proparate, coal-mines, and saleable underwoods,' and by the Rating Act of 1874 occupiers of all 'mines, rights of shooting, advertising boardings, and woods are also liable.' There are certain statutory exemptions, and the crown is not liable, because it is not specially mentioned in the rating statutes; it is, however, the practice of the government to make *ex gratia* payments. The basis of charge for rates in England and Wales is the 'rateable value'; it may be defined as 'the rent at which the property might reasonably be expected to let from year to year free of all the usual tenants' rates and taxes, and title commutation rent-charge, if any, and deducting therefrom the probable average annual cost of repairs. . . . ' Till the new 'General Rate' of the 1925 act comes into operation there may be levied in an urban district—outside the Metropolis—a Poor Rate, General Rate, and a Borough Rate, all for practical purposes, charged on the basis of the 'rateable value.' London is not affected by the new legislation, so that the existing 'General Rate' of the Metropolis will continue; by it the expenses of local govern-

ment are met. In a 'rural' area the expenses of local government, including those of the County Council, have usually been raised by means of the Poor Rate. The accuracy of the rateable value of property, as it is shown in the Valuation List, may be questioned by a ratepayer—firstly, by means of an 'objection' to the assessment committee, and then if he is 'aggrieved' by the decision of that body by an appeal to Special or General Sessions.

As soon as the Rating and Valuation Act, 1925, comes into force, it will apply to England and Wales, but not to Scotland, Northern Ireland, or London. It drastically alters the administrative machinery for the making of valuation lists and the collection of rates; it does not alter the basis on which rates are to be levied—viz. the rateable value. Overseers are superseded by the 'rating authority,' which is to make the valuation list and the rates founded on it. This 'rating authority' is practically the local government authority of the area. The parish, as a rating area, is abolished, and in its place is put the local government area. While there are minor exceptions, the rate which these new authorities will 'make, levy, and collect' is to be a consolidated rate known as the 'General Rate,' and will include all the rates heretofore made. It is to be assessed at a uniform amount in the pound over the whole rating area on the occupiers of the various properties on the basis of the rateable values. The procedure by which the rateable value of a property is to be fixed is by means of the making of a valuation list, which is to be prepared by the 'Rating Authority.' An objection may be made to this list to an assessment committee on account of its 'incorrectness or unfairness.' This objection must be heard and decided by the committee. If a ratepayer is still dissatisfied he may appeal to the Quarter Sessions for the county or place in which the property is situated, or by agreement the case may be taken to arbitration. If during the currency of a rate the value of a property is altered, the 1925 act provides procedure for the necessary adjustment, either by the rating authority or on the motion of the ratepayer.

The Rating and Valuation Act, 1925, deals with the rating of machinery by overriding the practice and law whereby practically all machinery and plant was rated, and providing that only machinery and plant used for the generation and storage of power, heating, cooling, lighting, ventilating, and draining premises, and plant in the nature of a building, such as a gas-holder, shall be treated as part of the property being rated; other plant and machinery is therefore exempt. This rule does not apply, however, to properties valued on a 'receipts and expenditure' basis.

The new 'General Rate' is to be made and collected as the old Poor Rate, so that the various statutory exemptions given to churches, chapels, and voluntary schools continue. Agricultural land, in which expression are now included buildings used solely for agricultural purposes (but not the farmhouses) is given a three-quarter exemption from the General Rate; and tithe, railways, canals, and woodlands are also given partial exemption conditioned by the amount of such exemption previously being received.

Both under the law as it exists to-day (1926) and as it will exist when the 1925 act comes into force, provision is made for the payment of the rates by the owners in the case of certain properties of the smaller classes instead of by the occupiers.

In Scotland the basis on which rates are levied is laid down in sect. 6 of the Lands Valuation (Scotland) Act of 1854 as 'the rent at which, one year with another, such lands and heritages might

in their actual state be reasonably expected to let from year to year.' Where a rent is paid under an agreement fixed by the higgling of the market at arm's length, without any grassum or consideration, then it is to be taken as the 'annual value,' except in the case of ordinary properties let upon a lease the stipulated duration of which is more than twenty-one years, or in the case of mineral properties more than thirty-one years, and then the 'annual value' must be arrived at by the assessor by estimating that value at the date of the making of the valuation list. Estimation of value is also necessary where a property is occupied by the owner. For a property to form the basis of liability for rates in Scotland it must consist of one or more of the following: 'lands, houses, shootings, deer forests, fishings, woods, copse and underwood from which revenue is actually derived, ferries, piers, harbours, quays, wharfs, docks, canals, railways, mines, minerals, quarries, coalworks, waterworks, lineworks, brickworks, ironworks, gasworks, and factories.' The deductions made for repairs and maintenance by the local authorities under sect. 37 of the Poor Rate Act of 1845 vary; the act simply provides that such deductions shall represent 'the probable average annual cost of the repairs, insurance, and other expenses, if any, necessary to maintain such lands and heritages in their actual state.'

In many cases, prior to 1895, improvements carried out to a property during the currency of a tenancy escaped rating, owing to the fact that the rent paid was taken as the measure of annual value. It was not till such lease expired that these improvements could be allowed to affect the annual value. Now, however, such improvements may be brought to assessment, except in the case of improvements to agricultural properties and to some mineral properties. The accuracy of the annual value inserted in the valuation roll may be questioned by a ratepayer by getting the assessor to alter the list, failing that by appeal to county valuation committees or magistrates, or the borough valuation committee, and lastly to the Lands Valuation Appeal Court.

Rath, the Irish name for a prehistoric Hill-fort (q.v.).

Rathenau, WALTHER, German industrialist, financier, and statesman, born 29th September 1867 at Berlin, was educated there and at Strasburg. A prominent business magnate, Rathenau became conspicuous in the early years of the Great War by his activities to keep Germany supplied with raw material. As minister of reconstruction (1921), and foreign minister (1922) of the Weimar ministry, he negotiated several important agreements regarding reconstruction. He was murdered in Berlin 24th June 1922. A keen student of social and economic problems, Rathenau published numerous books, among them being *Zur Kritik der Zeit* (1916), *Von kommenden Dingen* (1917), and *Der Kaiser* (1921).

Rathenow, a town of Prussia, on the right bank of the Havel (here crossed by a stone bridge), 43 miles by rail W. by N. of Berlin. Optical

instruments, wooden wares, machinery, bricks and tiles, are made. Pop. (1925) 27,553.

Rathkenle, a town of Ireland, on the river Deel, 19 miles SW. of Limerick by rail; pop. 1700.

Rathlin, a crescent-shaped island off the coast of Antrim, 6½ miles N. of Ballycastle. Measuring 6½ by 1½ miles, and 3398 acres in area, it has fine cliffs, consists of columnar basalt and limestone, and attains a maximum altitude of 449 feet. The soil in the valleys is fertile, but fishing is the leading industry. Rathlin is identified with the *Ricinia* of Ptolemy, *Ricina* of Pliny, and *Raghlín* or *Ragherin* ('fortress of Ireland') of later writers. St Columba established a church here in the 6th century; and Bruce in 1306 is fabled to have taken refuge in a castle, now a ruin. The population has fallen from over 1000 in 1841 to 350.

Ratibor, a town of Prussian Silesia, stands on the left bank of the Oder, 44 miles SSE. of Oppeln. It is the chief town of the former principality of Ratibor, which, a sovereign duchy from 1288 to 1532, became subject to Prussia in 1742. The town has foundries and engineering works. Pop. 41,000.

Ratich, WOLFGANG (sometimes called RATKE or Latinised as RATICHUS), educationist, was born at Holstein in 1571, based a new system of education on Bacon's philosophy, which he expounded to the German princes at Frankfurt in 1612, and had an opportunity of putting into practice at Kothén in 1618, by favour of the prince of Anhalt. His principle was the realistic one of proceeding from things to names, and from the mother-tongue to the study of foreign ones. But he got into bad relations with the clergy and with his patron, and was actually imprisoned for eight months. A second chance given him at Magdeburg in 1620 ended also in failure, and after some years of ineffective wanderings he died at Erfurt in 1635.

There are monographs on him by Krause (1872), Störl (1876), and Schumann (1876); and see R. H. Quick, *Essays on Educational Reformers* (1868; new ed. 1890).

Ratio. See PROPORTION, FLUXIONS.

Rationalism, as 'a system of belief regulated by reason,' might be expected to mean the opposite of irrationality, crass ignorance, and perverse prejudice; and the growth of rationalism would then mean the progress of civilisation, the development of the intellectual and moral nature of men and nations. It is nearly in this sense that Lecky uses the word; attributing to its wholesome influence the decay of the belief in magic, witchcraft, and other hideous superstitious, and the substitution of a kindly tolerance in place of blind zeal for persecution.

But in ordinary English usage, general as well as theological, the connotation of the word is substantially different. Rationalists in ordinary parlance are those who are more 'liberal' or 'advanced' than the main body of the orthodox; in especial those who take a 'low' view of inspiration, and explain away the miraculous. Rationalism is not so much a body of doctrine as a mood of mind, a tendency of thought shown in the attempt to apply to religious doctrine, to biblical literature and history, the same methods of research and proof as are used in science and history generally, and the literatures of all times and peoples. This feature is recognised with approval by Lecky in his wider use of the word: 'Rationalism,' he says, 'leads men on all occasions to subordinate dogmatic theology to the dictates of reason and conscience. . . . It predisposes men in history to attribute all kinds of phenomena to natural rather than to miraculous causes; in theology to esteem succeeding religious systems the expression of the wants and aspirations of that religious sentiment which is implanted in man; and in ethics to regard as duties only

those which conscience reveals to be such.' Rationalism, not being a system but a temper or drift of mind, has different aims at different times. Opinions are expounded in sermons and books by theological professors without proving serious stumbling-blocks to the majority, which thirty years earlier would by all but a small minority have been regarded as distinctly rationalistic. Thus, not very long ago, it was alarming rationalism to dispute the Mosaic authorship of Genesis, the Solomonic authorship of the Song of Songs, and the Davidic authorship of any of the Psalms; now the newer view is assumed by orthodox teachers. Rationalism of this kind is a transition stage, but not necessarily a transition to unbelief.

The rationalistic temper may be traced in almost every age of the church's history: no doubt the extreme representatives of the Petrine party in sub-apostolic times regarded Paul's views as lax and rationalistic. If the Reformation was not rooted in rationalism (as to Catholics it seems to have been), many of the contentions of the reformers were such as all rationalists accept and sympathise with. Zwingli was a rationalist to Luther and the Lutherans; Socinus was on some points a thorough rationalist. The dry and barren dogmatic orthodoxy of Germany in the 17th century fostered a rationalism as cold and unspiritual. In the England of the 18th century, during the Deistic controversies, the Evangelicals of Germany thought, not altogether unjustly, that some of the most conspicuous opponents of the deists were not themselves free from the charge of rationalism; and the Evangelicals of Scotland regarded the 'moderates' of the 18th century, however orthodox in dogma, as thoroughly rationalistic in spirit. Rationalism is not so much opposed to orthodoxy as to mysticism, and what was called variously fanaticism, enthusiasm, 'high-flying,' and methodism. A soulless orthodoxy has not seldom been opposed by a fervent piety that by a not unnatural antithesis has tended to run into heretical extremes; while, on the other hand, actual rationalists have often been foremost amongst the champions of religion, and of revealed religion, against radical freethinking, deism, naturalism, and materialism.

In Germany the term rationalism is more definite in its reference than in England, but is not always used in quite the same sense. The two defective and mutually opposed schools of thought that Kant sought to supersede by his critical philosophy were, on the one hand, a shallow empiricism, and on the other a baseless and overweening metaphysical dogmatism or rationalism. Bacon also contrasted empirical philosophers with rationalists who spin their systems as spiders do cobwebs out of their own bowels. Wolff presents the most conspicuous example of the philosophical rationalism which held that all that is in heaven above and earth beneath could be 'proved' by pseudo-mathematical methods; and as God, responsibility, and immortality were amongst the things that could be proved at endless length and in various ways, this philosophical rationalism led directly up to a rationalist theology, which consisted mainly in a series of dogmas to be demonstrated from the philosophical axioms, including some at least of the doctrines of revealed religion. What in revelation could not be demonstrated according to this scheme was disallowed or explained away. Practical religion became in the *Aufklärung* a system of mere utilitarian morals.

Kant prepared the way for a deeper view of man, history, and the universe; but his own explicit statements on positive religion were pronouncedly rationalistic; and the negative side of his philosophy was well calculated to lay the foundations

of another school of theological rationalists (often called *Vulgar-rationalismus*), of whom Tieftrunk (died 1837), Bretschneider (1776-1848), and Wegscheider (1771-1849) may be taken as representatives. De Wette (1780-1849) shows the transition to Schleiermacher, who (though in the English sense of the word he was an outspoken rationalist) combined what was best in the opposing schools of rationalists and supernaturalists, founded a higher and truer religious philosophy, and heralded even the 'pectoral theology' of the mediation school.

But it was not in the sphere of speculation and dogma, but in that of biblical criticism, that German rationalism accomplished its main work, and left its deepest mark on subsequent theological development. In the early 18th century the 'Germans in Greek were sadly to seek,' as English scholars thought: the Germans themselves admitted that in studying the Scriptures they failed to escape from dogmatic presuppositions, and that it was the English divines who approached the New Testament in a historical spirit, which in the Germany of that day caused misgivings. It is noteworthy that Semler (1725-91), 'the father of rationalism,' obtained the doctorate for a thesis written against Whiston, Bentley, and other English scholars in defence of the 'three heavenly witnesses' of 1 John, v. 7. Semler in the schools, supported by Lessing and Herder in literature, was soon teaching that the books of the Bible must be studied as human productions: Eichhorn (1752-1827) thoroughly accepted and applied that principle. Rationalist criticism was carried to an absurd length by Paulus (1761-1851), who taught that the Gospels contained natural and not supernatural events, and whose most ingenious but inept 'explanations' of the miracles of the New Testament, 'retaining everywhere the husk but surrendering the religious kernel,' were made a laughing-stock by Strauss. Strauss's 'mythical theory' (excessively rationalist in the English sense of the term) was in its turn superseded by Baur (q.v.) and the Tübingen school, whose work marked the opening of an important new period in scriptural criticism. The 'notes' of the newer criticism, whether more or less rationalist from the older English point of view, are the conviction that all truth is one, whencesoever derived, and the willingness to accept what is apparently established by the consensus of scholars even where this involves giving up the belief in the inerrancy of Scripture. Many of the contentions of self-confident and aggressive rationalism have long since mutually destroyed one another. Nothing can be more contrary to the true historic and scientific spirit than the assumptions of a reckless sciolism: there is a false and a true rationalism; and it should be remembered that much that is now most surely believed by all has at one time or another been branded as rationalistic.

Ratisbon (Ger. REGENSBURG), a town of Bavaria, stands on the right bank of the Danube, 82 miles by rail NNE. of Munich. Formerly a free city of the empire and seat of the Diet, Ratisbon presents a strongly marked mediaeval character, with narrow crooked streets, and high, many-cornered, gabled houses. Among its churches the most remarkable is the noble Gothic cathedral, begun in 1275, but not completed till 1534, and restored in the 19th century. The Church of St James, formerly belonging to the Irish (*Scoti*) Benedictines, dates from the 12th century, and is built in the pure Byzantine style. The old town-hall was used for a century and a half (1645-1806) as the place of meeting for the imperial diet. At the Golden Cross Inn Charles V. met the mother of his son Don John of Austria. There are numerous interesting private dwellings, as the Thurn and Taxis Palace, with library, picture-gallery, &c., the royal villa, and others. A stone bridge (1135-46), 1024 feet long, connects Ratisbon with the busy trading suburb of Stadt am Hof. The manufactures include porcelain and stoneware, brass and steel wares, leather, tobacco, lead-pencils, chemicals, &c.; and there is an active trade, especially in corn and salt. Pop. (1875) 31,487; (1890) 37,365; (1925) 76,918. Originally a Celtic town, Radasbona (whence Ratisbon) was made by the Romans a frontier fortress. Later it was the capital of the Dukes of Bavaria. Frederick II. declared it (1245) a free imperial city. During the 14th century it was one of the most populous cities of southern Germany. Here were signed the Ratisbon Interim (q.v.) in 1541 and the armistice between France and Austria in 1684. The city was stormed by Duke Bernhard of Weimar in 1633, and by both the Austrians and the French in 1809. It was ceded to Bavaria in 1810.

Ratnagiri, a coast-town of India, 136 miles S. by E. of Bombay, with a fort and sardine-fishery; pop. 18,500.

Rattan, a walking-stick made from the stem of a palm that grows in Sumatra. See PALM.

Rattany. See RHATANY.

Rattazzi, URBANO, an Italian statesman, was born at Alessandria, June 29, 1808. He studied law at Turin and practised as an advocate with great success at Casale. After the proclamation of the constitution in 1848 he was elected member of the Second Chamber for Alessandria, and began his political career as a democrat. His eloquence and liberal principles raised him to the ministry: Gioberti made him minister of the Interior and later of Justice; but after the defeat of Novara he was obliged to retire along with the rest of the ministry. When Napoleon III. threatened the liberty of Piedmont, Cavour, Rattazzi, and their parties joined together to defeat his schemes, and in 1853 Rattazzi took the portfolio of Justice under Cavour, and presented the bill for the abolition of convents. Being accused of weakness in suppressing the Mazzinian movement in 1857, he retired from office early in the following year. In 1859, however, he was back again in office as minister of the Interior. The threatened cession of Savoy and Nice, which he opposed, led to his retirement in 1860. Having changed his views on this point, he was in March 1862 entrusted with the formation of a new ministry, but had to resign at the end of the year in consequence of his opposition to Garibaldi; and once more prime-minister for six months in 1867, he lost the post for the same reason. He

died at Frosinone, 5th June 1873. A want of stability was his chief drawback as a statesman.

His Speeches were edited by Seovazzi (8 vols. Rome, 1876-80). See a Life by Morelli (Padua, 1874), and Madame Rattazzi's *Rattazzi et son Temps* (Paris, 1881).

Rattlesnake (*Crotalus*), a genus of highly specialised venomous snakes in the sub-family Crotalinae or pit vipers, so called because of a sensory pit between the eye and the nostril. At the end of the tail is the 'rattle,' an instrument composed of a number of horny bells formed at successive moults. As they get worn some break off and others replace them, the total number at one time rarely reaching twelve. The bells are loosely jointed on one another, so that they produce a shrill noise (like that of an alarm-clock) when very rapidly vibrated by the excited snake. Rattlesnakes range from Southern Canada to Northern Argentina. The common species of the United States is *C. horridus*, about 4 feet long; and there are some ten others—e.g. *C. durissus*, which attains a length of 8 feet. Nearly related genera without rattles are *Ancistrodon* (including the Moccasin-snake or Copper-head) and *Lachesis* (including the *Per-de-lance* of South America).

Rattlesnakes are naturally sluggish and prefer defensive to offensive tactics, except when on the track of their natural prey—rabbits, rats, squirrels, and other small mammals. Not a few ideas about rattlesnakes must be dismissed as false; they do not fascinate or charm mammals or birds, though these may be overcome by an almost paralyzing

with this triumph of his art, but commenced a new statue of the queen, which he finished eleven years afterwards, a masterpiece of sculpture, now in the palace of Sans Souci. After this he lived principally at Berlin, but occasionally visited Rome, Carrara, and Munich. He laboured indefatigably in his profession, and by 1824 had executed seventy busts in marble, of which twenty were of colossal size. His works include two colossal bronze statues of Field-marshal Blücher (1827), a bronze statue of Maximilian of Bavaria (1835), and statues of Albrecht Dürer, Goethe, Schiller, and Schleiermacher. His masterpiece is the magnificent monument of Frederick the Great (1851) which adorns Berlin. He died at Dresden, 3d December 1857. See Life by Eggers (1873-90).

Raues Haus ('the Rough House,' so called) is the name of a great institution founded on 1st November 1831 and managed by Johann Heinrich Wichern (1808-81) at Horn, near Hamburg, in connection with the German Home Mission (*Innere Mission*). It is partly a refuge for morally neglected children; partly a boarding-school for the moral and intellectual education of children of the higher classes; lastly, a training-school for those who wish to become teachers or officials in houses of correction, hospitals, &c., in promotion of the objects of the Home Mission. Opened by Wichern with twelve neglected children, it has since then been very much enlarged. See works on the subject by Wichern (1833-83).

Raumer, FRIEDRICH LUDWIG GEORG VON, German historian, was born at Wollitz, in Anhalt, on 14th May 1781, studied law at Halle and Göttingen, and entered the Prussian state service in 1801. In 1811 he accepted the chair of History and Politics at Breslau; in 1819 he was called to fill the similar chair at Berlin. He was for some time secretary of the Berlin Academy. In 1848 he was sent to Paris as ambassador of the German parliament. He died on 14th June 1873. The first scientific historian to popularise history in German, Von Raumer wrote *Geschichte der Hohenstaufen* (6 vols. 1823-25), his best book, based on critical research, and agreeably written; *Geschichte Europas seit dem Ende des 15. Jahrhunderts* (8 vols. 1832-50); *Beiträge zur neueren Geschichte* (5 vols. 1836-39); and edited the useful *Historisches Taschenbuch* from 1830. In the years 1830-43 he journeyed in England, Italy, and the United States, and wrote books dealing with each country. See his *Lebenserinnerungen und Briefwechsel* (2 vols. 1861).

Raumer, KARL GEORG VON, geologist and geographer, a brother of the foregoing, was born 9th April 1783 at Wollitz, studied at Göttingen and Halle, and at the Mining Academy at Freiberg, was appointed professor of Mineralogy at Breslau in 1811, was translated in 1819 to Halle, and finally, in 1827, was appointed professor of Natural History at Erlangen, where he died 2d June 1865. His most ambitious book was *Geschichte der Paläozoologie* (1843-51), a portion of which was issued separately as *Die Erziehung der Mädchen*. His most popular books were, after these, *Beschreibung der Erdoberfläche* (6th ed. 1866); *Paläontologie* (4th ed. 1860); and *Lehrbuch der allgemeinen Geographie* (1832; 3d ed. 1848). He also wrote books on his special study, as *Geognostische Fragmente* (1811) and *ABC-Buch der Kristallkunde* (1820-21). See his Autobiography (1866).—His son, RUDOLPH VON RAUMER (1815-76), professor at Erlangen, won high repute in Teutonic philology.

Ravalliac, FRANÇOIS (1578-1610), a bankrupt schoolmaster, who, after long imprisonment and a brief service in the Order of Fenillants, was moved by Catholic fanaticism to stab the heretic Henry IV. (q.v.) of France. He was tried (with awful

Rattlesnake (*Crotalus horridus*) in act of striking.

fear; the rattling does not lure prey nor attract mates, but is rather a reflex expression of excitement, apparently warning off molesters on whom the snake is doubtless unwilling to expend energy in the exhausting act of striking; finally, the number of rings does not necessarily indicate the age of the animal, though new rings seem to be added at successive sloughings. Rattlesnakes are generally nocturnal. The young are brought forth alive. The poison is very deadly, rapidly paralysing the nerve-centres and affecting the respiratory and circulatory functions. When a man is bitten it is customary to ligature above the wound, to suck out the poison, to use stimulants freely, and to inject antidotes such as permanganate of potash. Often, however, the result of the bite is fatal (see SNAKE).

Ratray, a police burch of Perthshire, on the Erich, opposite Blairgowrie. Pop. 1700.

Rauch, CHRISTIAN DANIEL, sculptor, was born at Avelsen, in Waldeck, 2d January 1777. In 1797 he became valet to Frederick-William III., king of Prussia, but, resolving to devote himself to art, was enabled by the generosity of a nobleman to study at Rome, where he enjoyed the friendship of Thorwaldsen, Canova, and Wilhelm von Humboldt, the Prussian minister. In 1811 he was called by the king of Prussia to Berlin to execute the monumental statue of Queen Louisa, now at Charlottenburg. Rauch was not, however, quite satisfied

tortures), and torn asunder by horses. See Loiseleur, *Ravallac et ses Complices* (1873); J. and J. Tharaud, *La Tragédie de Ravallac* (1913).

Ravel, MAURICE, French composer, was born 7th March 1875 at Ciboure (Pyrénées), and studied music at Paris under Fauré. His output comprises two one-act operas, *L'Heure espagnole* (1907) and *L'Enfant et les Sortilèges* (1925), a ballet *Daphnis et Chloé* (1912), a string quartet (1903), a trio (1914), *Gaspard de la Nuit* (1908) and other piano works, *Histoires Naturelles* (1906) and other songs, and various works for orchestra. Ravel's style, influenced perhaps by that of Chabrier, is characterised by an exquisite clarity and reticence worthy of the 18th-century French clavichord writers; with a certain ironic humour, Ravel looks at classical forms through highly coloured modern harmonic spectacles, and brings them up to date, so to speak. His chamber music, especially, is of great brilliance and charm.

Ravelin. See FORTIFICATION.

Raven (*Corvus corax*), a species of Crow (q.v.), now somewhat rare in Britain except in remote regions or on rocky islands. It is, however, widely distributed in Europe, northern Asia, and North

Raven (*Corvus corax*).

America. The plumage is glossy black, with a purplish-blue lustre on some parts. The bill and legs are also black. In length the raven measures about two feet. The males are rather larger and more lustrous than the females. Very early in the year the bulky nest is built on a cliff or tree; the three to five eggs are bluish-green, with brownish spots. The raven's note tends to be harsh, but is refined at the pairing season, and the bird may be trained to parrot-like imitation with remarkable success. The flight is powerful, and the bird often soars high. On small mammals, such as rats, the raven is fond of feeding, and its attacks on game and even lambs have led to its extermination in many districts. In Scandinavia the raven was sacred to Odin, but in many countries it is a bird of ill omen. Instances are on record of ravens which lived for four-score years, and there is no doubt that its natural longevity is great. Three varieties or sub-species of the raven are known in North America. See CROW; and R. W. Schufeldt, *The Mythology of the Raven* (1890).

Ravenna, a city of Italy, 45 miles E. of Bologna, once close to, but now some 5 miles from, the Adriatic, with which it is connected by the Corsini Canal, is enclosed by walls 3 miles long, built by the Venetians in 1457 *sqq.* with five gates. It has been the seat of an archbishop since 438, and

possesses a museum, a public library, a picture gallery, &c. It has manufactures of silk, linen, paper, and glass, and a trade in wine and agricultural products. Agriculture has been much favoured by extensive drainage and reclamation works. The streets are wide, and the squares are adorned with statues of the popes. The exterior aspect of the town is not striking; but the interiors of the churches are exceedingly interesting. Pop. (1921) 22,442; of commune, 72,023.

Possibly a Thessalian settlement, afterwards held by the Umbrians, Ravenna passed to Rome as one of the cities of Cisalpine Gaul south of the Po. It first became famous under Augustus as the station of the Adriatic fleet, with Classis—a flourishing suburb—as its port, a site marked now only by a church, and separated from the sea by the pine forest celebrated by Dante, Boccaccio, Dryden, and Byron. Deserted by the sea, and strongly entrenched by canals and marshes, Ravenna became the refuge of the Emperor Honorius (402), and the capital of Italy for the next 350 years. Imperial until Romulus Augustulus doled the purple at the bidding of Odoacer (see ITALY), who ruled at Ravenna 476–493, it attained its greatest glory under Theodoric the Ostrogoth (493–526). Conquered by the generals of Justinian, Ravenna was the seat of Exarchs (q.v.) from Constantinople until 752, when it was taken by the Lombards, and afterwards by the Franks, by whom it was gifted to the pope. A republic in the early part of the 13th century, governed by its own dukes in the 14th, subject to Venice after 1440, it was won by Pope Julius II. in 1509, and continued papal until it became national in 1860.

Ravenna, chiefly on account of its numerous ancient churches, holds a unique position as 'the Pompeii of the 5th and 6th centuries'—that marked transitional period in late classical (or early mediæval) history. Many features of its architecture, as has recently been shown by Rivoira, are derived rather from Roman classical models than from the East. There are six churches of the time of Galla Placidia (390–450), the sister of Honorius and mother of Valentinian III., including her mausoleum. Theodoric, leaving, with rare religious toleration, the cathedral of S. Ursus (almost entirely rebuilt, 1734, though the baptistery with its splendid mosaics remains) and the other churches to the Catholics, erected for his Arian Goths the basilica of St Martin (now S. Apollinare Nuovo, with its marvellous mosaic processions of martyrs added about 560, when it was 'reconciled') as a cathedral, a baptistery (now Sta. Maria in Cosmedin), and S. Teodoro (now S. Spirito). He also built himself a large palace, remains of which were found in 1870 and 1908; while the building that bears the name is really a later guard-house; and a circular mausoleum outside the city walls, surmounted by an enormous block of Istrian stone, weighing over 300 tons. S. Vitale (well restored by Ricci, with contemporary portraits in mosaic of the emperor and Theodora)—the model for Charlemagne's cathedral at Aix-la-Chapelle—and the magnificent basilica of S. Apollinare in Classe belong to the age of Justinian. The round campaniles, perhaps of the 9th century, form another architectural feature peculiar to Ravenna.

Dante died at Ravenna, 14th September 1321, and is buried there. A column, 2 miles from the walls, commemorates the fall of Gaston de Foix at the head of the French army of Louis XII., after a bloody victory over the papal and Spanish troops, 11th April 1512. Byron resided at Ravenna from June 1819 to October 1821.

See Rivoira, *Lombard Architecture* (London, 1903), *passim*; Hutton, *Ravenna* (London, 1913).

Ravensburg, a town of Württemberg, 11 miles by rail N.E. of Friedrichshafen, on the Lake of Constance; pop. 17,000.

Ravenscroft, EDWARD, English dramatist of the later 17th century, evinced great skill in the writing of farce and in adapting themes of other dramatists. Of his plays, a dozen in number, the more important are *Mammoth* (1671), taken from Molière's *Le Bourgeois Gentilhomme*, *The Careless Lovers* (1673), *The London Cuckolds* (1683), *Dame Dobson* (1683), and *The Anatomist* (1697).

Ravenscroft, THOMAS (1592?-1635?), musical composer and author of *Melismata* (1611), and of a collection of psalm-tunes for four voices, *The Whole Book of Psalms* (1621) by various composers. Some of the tunes, such as St David's, Canterbury, Bangor, and many others, which have since become popular, are by Ravenscroft himself.

Ravenspur. See HUMBER.

Ravignan, GUSTAVE FRANÇOIS XAVIER DELACROIX DE, a celebrated Jesuit preacher, was born at Bayonne, 2d December 1795, was professor at Montreuil, and became famous in 1837 as preacher at Notre Dame in Paris. He died 26th February 1858. He published an Apology of his order in 1844, and in 1854 a more lengthened work with the same view, *Clément XIII. et Clément XIV.* See memoirs by Ponjoulat (1858) and De Ponlevey (1860; Eng. trans. New York, 1873).

Ravinala. See TRAVELLER'S TREE.

Rawal Pindi, a town and important military station of the Punjab, lies between the rivers Indus and Jhelum, 160 miles by rail N.W. of Lahore. Since the extension of the railway to Peshawar, and since the last Afghan war, the town has increased at a rapid rate. Pop. (1868) 28,586; (1881) 52,980; (1911) 86,483; (1921) 101,142. The place carries on an active transit-trade with Kashmir and Afghanistan. Here the Sikhs surrendered after their defeat at Gujrat (1849), and here too was held, in 1835, a great durbar or review, at which the Amir of Afghanistan met Lord Dufferin, Governor-general of India.

Rawitsch (Polish *Rawicz*), a town of Poland, 64 miles by rail S. of Posen; pop. 10,000.

Rawlinson, SIR HENRY CRESWICK, Bart., orientalist and diplomatist, was born at Chadlington in Oxfordshire, 11th April 1810, and entered the East India Company's army in 1827. In 1833 he proceeded to Persia to assist in organising the Persian army. During the six years he spent in that country he began to study the cuneiform inscriptions, and made a translation of Darius's famous Behistun inscription, which he published in the *Journal of the Royal Asiatic Society*. After he left Persia he was political agent in Kandahar during the troublesome times of 1840-42 (see AFGHANISTAN); he was appointed political agent at Bagdad in 1844, and consul-general there in 1851. He showed great bravery in the field, and remarkable skill and resource in diplomacy. In 1856, now made K.C.B., he was appointed director of the East India Company. In 1858-59 he was again in Persia as British minister; and was successively member (1868) and vice-president (1876) of the Council of India. In 1865-68 he sat in parliament for Frome. He held the presidency of the Royal Geographical Society (1871), to whose *Proceedings* he contributed valuable papers, a trusteeship of the British Museum (1879), and a directorship of the Royal Asiatic Society. He was made a baronet in 1891; and he died 5th March 1895. The 'father of Assyriology,' he wrote *A Commentary on the Cuneiform Inscriptions of Babylon and Assyria* (1850), *Outline of the History of Assyria* (1852), *The Cuneiform Inscriptions of Western*

Asia (with Norris and George Smith, 6 vols. 1861-80), and *England and Russia* (2d ed. 1875). See the Life by his brother (1898).

That brother, GEORGE RAWLINSON, orientalist and historian, was born at Chadlington in 1812, took a first-class in classics from Trinity College, Oxford, in 1838, and was elected a Fellow of Exeter College in 1840. In 1859 he preached as Bampton Lecturer on *Historical Evidences of the Truth of the Scripture Records*, and two years later was chosen Camden professor of Ancient History. In 1872 he was made a canon of Canterbury. His historical publications cover nearly the entire history of the ancient Orient. The series opens with an annotated translation of Herodotus (4 vols. 1858-60; 3d ed. 1876), which was followed by *The Five Great Monarchies of the Ancient Eastern World* (4 vols. 1862-67), *The Sixth Great Oriental Monarchy of Parthia* (1873), *The Seventh or Sassanian Empire* (1876), *History of Ancient Egypt* (1881), and *History of Phœnicia* (1889). He also wrote smaller popular works, commentaries, books on Scripture characters, sermons, and the article PHœNICIA in a former edition of the present work. He died 7th October 1902.

Rawlinson, SIR ROBERT, K.C.B. (1810-98), a great sanitary reformer in the Crimea and at home under the Local Government Board, and consulting engineer on water-supply and river pollution.

Rawmarsh, a town in the West Riding of Yorkshire, 24 miles N.E. of Rotherham (included in Rotherham parliamentary borough), with iron-works and collieries; pop. 18,000.

Rawtenstall, a municipal borough of Lancashire (incorporated 1891), 8 miles N. of Bury, forms part of Rossendale parliamentary borough. It manufactures cottons, woollens, shoes and shippers. Pop. 28,000.

Ray, a popular name applied to most of the lat cartilaginous fishes or Elasmobranchs. Skate (*Raja batia*), Thornbacks (*R. clavata*), Electric Rays (to *Torpedo*), Sting-rays (e.g. *Trygon*), Eagle-rays (e.g. *Myliobatis*) are representative. They lead a somewhat sedentary life at the bottom of the sea, moving sluggishly by undulations of the pectoral fins which form a large part of the flat body. They are all cannivorous. The true rays, of which skate and thornback are typical and very common species, form the family *Raidae*. Many attain a large size, sometimes measuring six feet across. The flesh is edible, but strongly flavoured and not very highly esteemed. See CARTILAGINOUS FISHES, DEVIL-FISH, ELECTRIC FISHES, SKATE, STING-RAY.

Ray, or WRAY, JOHN, naturalist, was born a blacksmith's son at Black Notley, near Brintree, in 1627. From Brintree free-school he went up to Cambridge, where he was fellow, Greek lecturer, mathematical tutor, and junior dean in Trinity College, but after a time began to devote himself entirely to the study of natural history. At the Restoration he accepted Episcopal ordination, but was ejected by the 'Black Bartholomew' (1662). Thereupon, accompanied by a kindred spirit, Francis Willughby, a friend and former pupil of his own, Ray travelled over most of the United Kingdom, collecting and investigating botanical and zoological specimens; and in 1663 they started on a tour through the Low Countries, Germany, Italy, and France, with a similar object, Willughby taking the zoology under his charge, and Ray the botany. In 1667 Ray was elected a Fellow of the Royal Society, to whose *Transactions* he occasionally contributed valuable papers. In 1672 his friend Willughby died, leaving him guardian to his two sons. After several changes of residence, in 1679 Ray settled down in his native village, where he died, 17th January 1705. As a botanist and zoologist he ranks very high, the

classification of plants which he proposed being practically in the main the foundation of what is now known as the 'Natural System' of classification (see BOTANY). Ray's zoological works are considered by Cuvier as the foundation of modern zoology. The chief of his works on botany are *Methodus Plantarum Nova* (1682); *Catalogus Plantarum Angliæ* (1670), the basis of all the subsequent floras of Britain; and *Historia Plantarum* (3 vols. 1686-1704). His zoological works include the *Synopsis Methodica Animalium* (1693) and three posthumous volumes on Birds, Fishes, and Insects, published by Dr Derham. He was also the author of some theological works. His friend Willughby, having collected the materials for an extensive work on the animal kingdom, left to Ray the task of arranging and classifying them (see WILLUGHBY). See *Memorials of Ray* (1846), and his *Correspondence* (1848), both edited by Dr E. Lankester for the Ray Society, which was founded in 1844.

Rayahs, the Christian peasantry, labourers, and small farmers, who lived under Turkish rule, or rather misrule, in the Balkan peninsula. The word means 'cattle,' and as cattle these people were treated by their Turkish masters in Bosnia, Serbia, Bulgaria, and the neighbouring states.

Rayleigh, JOHN WILLIAM STRUTT, third BARON, P.C. (1905), O.M. (1902), P.R.S. (1905-8), was born 12th November 1842, studied at Trinity College, Cambridge, and was the senior wrangler (1865), Smith's prizeman, and fellow of his college (1866). He was professor of Experimental Physics at Cambridge from 1879 to 1884; in 1881-1905 Tyndall's successor as professor of Natural Philosophy at the Royal Institution; and was Chancellor of Cambridge University. He was mainly instrumental in founding and fostering the National Physical Laboratory. He edited Clerk-Maxwell's *Heat*, and was author of *The Theory of Sound* (1877-78). His *Scientific Papers* were collected in 6 vols. (1899-1920). In 1894, with Sir William Ramsay, he separated from atmospheric nitrogen the new gas argon—hitherto undetected, but constituting about 1 per cent. of the atmosphere. He died 30th June 1919. See Life by his son the fourth baron (1924).

Raynouard, FRANÇOIS JUSTE MARIE, poet and philologist, was born at Brignoles, 8th September 1761, studied at Aix, and in 1791, an advocate and a deputy, joined the Girondins, and was for a time imprisoned. His poems and tragedies were successful, and in 1807 he was elected to the Academy, of which he became perpetual secretary in 1817. A member of the imperial legislative body from 1806, he continued to produce dramas, but towards the fall of the Empire turned his attention to linguistic and particularly Provençal studies. His researches into the origin and transformations of this tongue led to many valuable discoveries, though his theories of the relation of the language of the troubadours to the other Romance tongues are not now accepted. Raynouard died at Passy, near Paris, 27th October 1836.

Râzi. See RHazes.

Razor. See BEARD, CUTLERY.

Razor-bill, or RAZOR-BILLED AUK (*Alca torda*), a species of Auk (q.v.), very common on the coasts of Britain and of all the northern parts of the Atlantic Ocean. In March and April they congregate in great numbers on cliffs and islands for the breeding season. A single egg, measuring about 3 inches in length, and of a white or light brown colour streaked with dark brown, is laid in a crevice or under a ledge of rock. The male helps to sit on the eggs. The razor-bill

measures about 17 inches. The plumage is of a glossy greenish-black on the upper parts and dazzling white underneath. It is a handsomer bird than the Guillemot (q.v.), and can be readily distinguished from it at a distance by its upturned

Razor-bill (*Alca torda*).

tail. The flesh of the razor-bill is used for food, and the eggs are esteemed a delicacy. They are less easily obtained than those of the guillemot, being usually laid in concealed situations.

Razor-fish, or RAZOR-SHELL (*Solen*), a genus of bivalves of which the common British species *S. siliqua* and *S. cassis* are familiar examples. The shell is remarkably elongated, and gapes at both ends, the siphons are short, the foot is large and powerful. The species are numerous, and inhabit

Razor or Solen-fish (*Solen siliqua*).

the sands of all seas except in the coldest parts of the world. Some of the tropical species have shells of great beauty. The solens burrow in sand, making vertical holes 2 or 3 feet in depth, and ascending and descending by means of their foot, which is capable of being elongated and contracted to bore a passage for the animal, and to drag it through. They are used for food, and also by fishermen for bait. To obtain them, a hooked iron implement is used. Another method is to drop a quantity of salt on the mouth of the hole, which causes them to come up, when they are quickly seized.

Ré, ÎLE DE (*Rex insula*), is a small, low-lying island off the coast of the French department of Charente-Inférieure, opposite the city of La Rochelle, from which it is separated by the Pertuis Breton. It is about 18 miles long and 3 broad, and measures 28 sq. m. The west coast is rocky; on the east side there are some good harbours. The inhabitants are chiefly engaged in the preparation of salt, with oyster farming and wine-making.

Reade, CHARLES, novelist and playwright, was born at Ipsden House on 8th June 1814. The youngest of eleven, he came on both sides of good lineage, his father an Oxfordshire squire, his mother a clever Evangelical; from her he

'inherited his dramatic instinct.' After five years (all flogging) at Illey, and six under two other and milder private tutors, in 1831 he gained a demyskip at Magdalen College, Oxford, and in 1835, having taken a third class in honours, was duly elected to a lay fellowship. Next year he entered at Lincoln's Inn, and in 1843 was called to the bar, meanwhile having made the first of many tours abroad and at home, and developed a craze for trading in violins. 'I studied,' he tells us, 'the great art of Fiction for fifteen years before I presumed to write a line of it; and it was not till 1850 that he put pen seriously to paper, 'writing first for the stage—about thirteen dramas, which nobody would play.' Through one of these dramas, however, he formed his platonic friendship with Miss Seymour, a warm-hearted actress, who from 1854 till her death in 1879 kept house for him. She animated, counselled, guided him; and, apart from his quarrels and lawsuits (which were many), his life after 1852 is little except a record of the production of plays and novels, by the former of which he generally lost money, by the latter won profit and fame. The plays include *Masks and Faces* (1852), written in conjunction with Tom Taylor, and having Peg Woffington for its leading character; *Gold* (1853), the germ, and *Sera Nunquam* (1865), the dramatised form, of *Never too Late*; and *Drink* (1879), an adaptation of Zola's *L'Assommoir*. Of his eighteen novels may be mentioned *Peg Woffington* (1853); *Christie Johnstone* (1853), the Newhaven fisher lass; *It is Never too Late to Mend* (1856), a tale of prison abuses and life in Australia; *The Cloister and the Hearth* (1861), its hero Erasmus' father, condemned, like Reade himself, to celibacy; *Hard Cash* (1863), against private lunatic asylums; *Griffith Gaunt, or Jealousy* (1866); *Paul Play* (1869), in conjunction with Dion Boucicault, against ship-knackers; *Put Yourself in his Place* (1870), against trades-unions; *A Terrible Temptation* (1871); and *A Woman-hater* (1877), for woman's rights. His last years clouded by sorrow and ill-health, he died at Shepherd's Bush on Good Friday, 11th April 1884, and was buried in Willesden churchyard beside his 'beloved friend.'

Charles Reade was not one of the greatest novelists of the century (who number three, at most four); but of the second order he is perhaps the best. He is sometimes coarse, sentimental sometimes rather than dramatic, and sometimes even dull, weighed down with authorities—the blue-books, books of travel, and the like, with which he fettered his imagination. With the greatest novelists one is conscious only of the story, with him one is always conscious of the story-teller; some tone or mannerism from time to time jars upon us. And yet what a story-teller it is. How he carries us with him, stirs us, saddens, gladdens, terrifies, delights. No novels are better than his to read aloud. For they hold the listeners spell-bound, and 'Bravo!' or oftener just a long-drawn 'Oh!' attests Reade's magnificent powers far better than can all the fine-spin criticisms in which A. concedes and B. denies him the gifts of humour and pathos; in which M. declares that 'Reade invented the True Woman,' and N. that 'of the woman who is essentially of our time he has never had even the faintest conception;' in which X. discovers 'in the short *Wandering Heir* at least half a dozen situations all new and all strong,' and Y. pronounces it 'very decidedly the worst of Reade's shorter stories.' These things need not perplex us, the simple admirers of *Griffith Gaunt*, of the fight with the pirates, of the bursting of the reservoir, and of the scenes at the gold-diggings. At the same time we may rejoice in the unanimous verdict that is passed by the critics on *The*

Cloister and the Hearth. Swinburne—from whom praise is praise indeed—placed it 'among the very greatest masterpieces of narrative.'

Charles Reade: *A Memoir* (2 vols. 1887), by his brother and a nephew, is a most unhappy piece of biography. See Swinburne's *Miscellanies* (1886); *Readiana* (1882), a collection of fragments; Justin McCarthy's *Reminiscences* (1889); and Coleman's *Charles Reade as I knew Him* (1903).

Reading, a municipal, parliamentary, and county borough, the capital of Berkshire, on the Kennet, near its influx to the Thames, 36 miles by rail W. of London (by road 39, by river 74). Its strong castle was wholly demolished by Henry II.; and the splendid Benedictine abbey, founded in 1121 by Henry I., who was buried here, is represented by considerable ruins and a fine gateway, restored in 1861, and surrounded by public gardens. Nine parliaments were held within its hall; and the last of its mitred abbots was hanged by Henry VIII., with two of the brethren. There are handsome municipal buildings and two excellent town halls, a lofty clock tower, a free library, museum, &c. Other buildings are the Italian assize courts (1861); a large grammar-school (1486; rebuilt 1870-71), of which Dr Valpy was long headmaster; St Laurence's Church (1434; restored 1868); and the Royal Berkshire Hospital. The university (1926) grew out of the University Extension College, founded in 1892 and made a university college ten years later. It is strong in agriculture and dairying. There are many excellent schools. One of the largest of the public parks was gifted in 1891 by Mr G. Palmer. Reading is an important mart for corn and other agricultural produce, and has manufactures of iron, paper, sauce, &c., whilst two of its industrial establishments are world-famous—Huntley and Palmer's huge biscuit-factory and Sutton's seed emporium. Reading, which is in the diocese of Oxford, gives title to a suffragan bishop. Its representation was reduced from two to one in 1885. The first charter was granted by Edward III. Pop. (1851) 21,456; (1881) 46,054; (1891) 55,752; (1921) 92,278. Reading suffered much from the Danes between 868 and 1006, and in 1643 surrendered to Essex after a ten days' siege. It was the birthplace of Archbishop Laud, Justice Talford, and Goldwin Smith, but not of Miss Edgeworth, who is often claimed as a native. It has memories also of Chaucer and Bunyan.

Reading, a city of Pennsylvania, capital of Berks county, on the left bank of the Schuylkill River, 51 miles by rail N.W. of Philadelphia. It is pleasantly situated on an ascending plain, and from the neighbouring hills draws its water-supply and abundant iron ore. The principal factories are iron and steel works. These include many rolling-mills, forges, foundries, furnaces, machine-shops, nail-works, &c. Reading also manufactures shoes, hats, cigars, leather, paper, bricks, &c. Settled in 1748, it became a city in 1847, and is the seat of an Episcopal bishop. Pop. 110,000.

Reading, a town of Massachusetts, 12 miles by rail N. by W. of Boston, with boot and shoe and radio apparatus manufactures. Pop. 7500.

Reading Beds. See Eocene System.

Reading In. See INDUCTION.

Real, an old silver coin and money of account of Portugal, Spain, Mexico, and the old Spanish possessions, the 4th part of the *pie*, or 4th of the *peseta*, the franc of the Spanish decimal system, which took its place after 1868. The real, not now a current coin, was first coined in Spain in the time of Pedro the Cruel. In Java the name was also applied to a weight for gold and silver articles, equal to 17 dwt. 14 gr. troy weight.

Real is a term used by lawyers to describe the nature of certain rights and actions. The rights of an owner of property are real rights—i.e. he has a right to claim some specific thing and hold it against all other persons. Contractual rights, on the other hand, are personal—i.e. they are good only against the person who is bound to perform the contract. Forms of action are classified according to the nature of the right which is in dispute. The Roman law gave an action *in rem* for the recovery of any thing, whether movable or immovable, which was withheld from the person entitled; an action *in personam* was the form in which compensation could be obtained for breach of contract or other wrongful act. In Scotland, and in other countries where the Roman law has been studied and followed, real rights and real actions are defined very much as they were defined by the civilians; England has taken a course of its own. At the time when the common law was taking shape land was of primary importance. The owner of chattels (movable things) was entitled to damages if his property was detained from him or converted to the use of another; but he had no real action to recover the thing itself. A real action was an action to recover land or some right connected with land. Some interests in land (e.g. the interest of a tenant under a lease) were regarded as personal rights against the owner; in technical language the interest of a tenant for years is a chattel real, or a chattel which savours of the reality. The English law of property framed all its rules with reference to these somewhat arbitrary distinctions. But the Land Transfer Act of 1897 enacted that real property, which used to pass to the heir or devise, should devolve, like personal property (and chattels real), in the first instance on the executors or administrators for distribution among the persons named in the will or the next of kin. This enactment applies only in cases of death after the year 1897, and, as regards deaths occurring after 1925, it is now replaced. But, as regards such deaths, the provision of the Act of 1897 is in substance re-enacted by the Administration of Estates Act, 1925, which provides that real estate to which a deceased person was entitled for an interest not ceasing on his death is to devolve on his personal representative just like a chattel real, and the personal representative, i.e. the executor, original or by representation, or administrator, for the time being, is to be deemed the heirs and assigns of the deceased within the meaning of all trusts and powers, and is to be his representative in regard to such real estate as well as in regard to his personal estate. The new enactment is, however, more explicit than the old as to what is meant by real estate. The expression real estate is defined to include chattels real, and land in possession, remainder or reversion, and every interest in or over land to which the deceased was entitled at his death, and real estate held in trust (including settled land) or by way of mortgage or security, but not money to arise under a trust for sale of land, nor money secured or charged on land.

Realgar. See ARSENIC.

Realism in philosophy is diametrically opposed to Nominalism (q.v.), as involving the belief that genus and species are *real* things, existing independently of our conceptions and their expression, and that these are alike actually the object of our thoughts when we make use of the terms. Again, as opposed to Idealism, the word implies an intuitive cognition of the external object, instead of merely a mediate and representative knowledge of it.

In art and literature the word Realism or Naturalism is employed to describe a method of representa-

tion without idealisation, which in France was raised to a system and claimed a monopoly of truth in its artistic treatment of the facts of nature and life. It claimed that the enthusiasms and exaggerations of romanticism must give place to a period of reflection and criticism; that we must not select from the facts put before our eyes, but merely register them and the sensations they engender for themselves alone, apart from all considerations of mere beauty, to say nothing of religion or morality; and that the experimental romance must follow the rigid methods of science, in being based alone on 'human documents' supplied from the close observation of the present, or from laborious erudition—the retrospective observation of the past. This militant Realism was the offspring of the Positive philosophy and the physiology and psychology of its age; and in effect, in the hands of its apostles, it became a new morality which reformed not by precept but by example, not by the attraction of the good, but by the repulsion of the evil. The practical result is that for French realists there is in the moral world only the evil, in the visible world only the ugly.

Realschulen. See EDUCATION.

Reaping, the act of cutting corn, was from time immemorial until far through the 19th century performed with an instrument called a reaping-hook or sickle. The sickles in use among the ancient Egyptians, Jews, and Chinese appear to have differed very little in form from those employed in Great Britain. The reaping-hook is a curved instrument of about a foot and a half in length, tapering from a breadth of about two inches at the butt-end, where it is fixed into a wooden handle. The edge is sometimes serrated; but, as a rule, it has long been made plain and sharp like a knife.

Fig. 1.—Ancient Reaping-machine.

In many parts of the British Islands it was supplanted by the scythe in the earlier half of the 19th century. In other parts it lived until the modern reaping-machine was ready to take the place of it as well as of the scythe. The sickle or hook did its work admirably, but it was necessarily slow. On small farms in some districts it is still employed; and occasionally on large farms, when the crop is much laid and twisted, it is resorted to. By the scythe corn can be cut at a rather less cost per acre than with the hook; but the work is not always so neatly done. As nice a stubble will be left by a good hand with the scythe, and often nicer than by the hook, but the sheaves are not, as a rule, so tidy after the scythe, though they will stack rather earlier. Of a fair working crop an adept at the scythe would cut 2 or 2½ acres per diem. The average, however, would not exceed 1½ acres. In fact, if the crop is heavy, that extent is a very hard day's work.

An attempt to trace the history of the reaping-machine would carry us far back into the earlier stages of agriculture. Pliny the Elder, who was born early in the 1st century of the Christian era, found a reaping-machine in Gaul. He says: 'In

the extensive fields in the lowlands of Gaul vans of large size, with projecting teeth on the edge, are driven on two wheels through the standing corn by an ox yoked in a reverse position. In this manner the ears are torn off, and fall into the van.' Palladius, about four centuries later, found a similar appliance for reaping corn in Gaul. He gives a more detailed but similar description of the machine. Fig. 1, copied from Mr Woodcroft's *Appendix to the Specifications of English Patents for Reaping machines*, represents what is conceived, from the descriptions, to have been the form of this ancient reaper.

In modern times the idea of a mechanical reaper appears to have originated with Capel Lofft (q.v.),

Fig. 2.—Samuelson's Self-delivery Reaping-machine.

who in 1785 suggested a machine something after the pattern of the ancient one described above. Between that time and the Great Exhibition of 1851 in London, from which the general use of mechanical reapers may be said to date, the patents taken out for reaping-machines were very numerous. Among the most promising of these may be mentioned those of Mr Gladstone of Castle-Douglas; Mr Smith of Deanston; Mr Kerr, Edinburgh; Mr Scott of Ormiston; Mr Dobbs, an actor in Birmingham; Mr Mann of Raby, near Wigton; and the Rev. Patrick Bell of Carnyllie, Forfarshire. In 1826 Mr Bell constructed an efficient

to agriculture. In America Mr Hussey and Mr M'Cormick took out patents for reaping-machines of superior character in 1833 and 1834 respectively. The movements of the cutters of these machines were various. A few were advancing only, some sidelong and advancing, others reciprocating and advancing, a large number continuous and advancing, and others continuous and alternate. The reciprocating and advancing motion is that now employed on the machines in use.

The principal difference in the machines now so largely used for cutting corn is in the form and character of the cutters, and in the mode of delivering the grain after it is cut.

The cutting knives are of two kinds—one, obtuse-angled and serrated; the other, acute-angled and for the most part plain. Both are attached to a bar, and are made to work through another bar of iron fitted with hollow fingers, called guard-fingers, which, projecting forwards, catch the standing corn, and retain it firmly until it is cut. The serrated knife saws through it, the plain knife clips it, as it were, the finger-guard forming the fixed blade of the scissors.

The delivery of the sheaves divides the machines into three kinds—(1) those delivered by manual labour; (2) those delivered by mechanical labour, or self-delivers; and (3) combined reapers and binders, which deliver the sheaves ready bound. The delivery of the sheaves by manual labour is now chiefly at the back of the machine, the side-delivery being generally abandoned, unless in the self-deliveries. In delivering the grain, a man, with a short-handled rake in his hand, sits upon the machine almost opposite the cutting apparatus. With this he inclines the grain towards the knife; and, when enough has been cut to make a sheaf, he rakes it off the platform of the machine, on to which it has fallen, and deposits it on the ground. With the back-delivery the sheaves must be tied up and removed out of the way of the machine before it comes round again. Such a reaper, therefore, always requires a full supply of hands to attend upon it. Carefully handled, this machine will take up laid and twisted crops admirably.

The mechanical or self-delivery machines, as they are generally called, are of two kinds—one lays the cut corn in swathes, the other deposits it in sheaves. Samuelson's sheaf-deliverer will be made plain by fig. 2. The machinery consists of a series of four rakes—two toothed and two plain—attached to an upright shaft in such a manner as to admit of a free ascending, descending, and horizontal motion. The two toothless rakes or 'dummies' are shorter in the arms by six inches than the other two, and are merely employed to incline the grain towards the cutter. By an ingenious eccentric motion, the rakes are made to sweep the sheaves off the platform at intervals of about 12 feet apart, to the side, and out of the way of the horses.

The more recent automatic combined reaper and binder has now almost entirely superseded other reaping-machines. The general

Fig. 3.—Howard's Binder.

and simple machine, which long continued in use, and several features of which are observable in the reapers of the present day. The inventor of this, the first machine of the kind in Scotland, received a public testimonial from agriculturists in consideration of the services he thus rendered

appearance and arrangement of Howard's light steel-frame sheaf binder is shown in fig. 3. The cutting portion of the binder is very similar to that of an ordinary reaping-machine. The cut grain as it falls back on the machine is conveyed by an endless web over the top of the

driving-wheel to the knotter. Here it falls into two arms called compressor jaws. These retain it on the knotter table till a sheaf of the prescribed size has accumulated. 'Whenever a sheaf of the desired size has been delivered to the compressors these relieve the tripper, which sets in motion the needle (carrying the binding twine) and the knotting apparatus. The needle is circular, and in its course it passes the band (twine) round the sheaf, when the band is caught by the knotter, and almost instantaneously a firm and secure knot is tied, while the needle is drawn back ready to operate on a new sheaf. As soon as the knot is tied and the string cut, the sheaf is ejected from the machine in a horizontal position, dropping gently on the ground on its side quite clear of the machine' (*Book of the Farm*). With a moderate crop of standing grain the binder in its various improved forms does its work in a most admirable manner, though when the crop is badly 'laid' it cannot be used satisfactorily. It is expeditious, and surpasses all other methods in neatness and thoroughness of work. When the binder was first introduced wire was the binding material. There were strong objections to its use, however, and it was not until twine was substituted that the invention made any headway. There are now several British firms engaged in making binders, which are gaining in popularity year by year.

See *Woodcroft's Appendix to Patents for Reaping-machines*; Jacob Wilson's 'Essay on Reaping-machines,' in *Transactions of Highland Society* for January 1864; Henry Stephens, *Book of Farm Implements and Book of the Farm*; Bond, *Farm Implements and Machinery*.

Reason. See the articles in this work on Psychology, Logic, Induction, Kant, Philosophy, and works cited under these.

Réaumur, RENÉ ANTOINE FERCHAULT DE, physicist, was born at La Rochelle, 28th February 1683, and studied in the Jesuits' College at Poitiers, and afterwards at Bourges. In 1703 he went to Paris, where he attracted general attention by the publication of three geometrical memoirs; and in 1708 he was elected a member of the Academy of Sciences, and was charged with the supervision of the *Description des Divers Arts et Métiers*, published under the auspices of the government. Réaumur lightened his labours with occasional researches into various subjects of natural history. These studies occupied him from 1708 to 1715, and were followed by a series of investigations into the condition of the woods, auriferous rivers, and turquoise mines of France. The collections of Memoirs of the Academy of Sciences from 1722 till 1725 contain a number of papers by Réaumur, in which he details his discoveries of the mode of producing steel from iron, and of the mode of tinning iron. For his researches he received from government 12,000 livres, which he spent in promoting the industrial arts. In 1739 he produced an opaque glass equal to the porcelain of Saxony and Japan. He invented the Thermometer (q.v.) which bears his name. He died of a fall from a horse, 17th October 1757, leaving behind him a voluminous collection of works on all the subjects above stated, also a treatise on 'the silk of spiders,' a number of memoirs (1731-40), containing his thermometric researches on air, and on mixtures of fluids with fluids or solids, and his *Mémoires pour servir à l'Histoire des Insectes* (Amsterdam, 12 vols. 1737-48).

Rebec (Arabic *rebab*), an ancient musical instrument of the violin kind, like the mandoline in shape, was narrow towards the neck, and gradually enlarged till it rounded off at the lower end. Milton, in his *L'Allegro*, characterises this instru-

ment as the 'jocund rebec.' It is still used in North Africa and in the East.

Rebecca Riots, a series of popular outbreaks which originated in Carmarthenshire in 1843-44, and quickly spread over Pembroke, Cardigan, and Brecon. They grew out of the impatience of the people at the great increase of toll-gates on public roads, and owed their singular name to their adopting as a motto Genesis, xxiv. 60. Bands of men five hundred strong, their leaders disguised in women's clothes, scourged the country by night, threw down the toll bars, and then dispersed. A strong force of soldiers was poured into the country, but the rioters offered an obstinate resistance, and were not put down without great difficulty and considerable bloodshed. The commission appointed by government to inquire into the causes of the outbreak found that it grew out of a genuine public grievance, whereupon measures of relief were introduced, and those rioters seized were punished lightly.

Rebellion. 'The Great Rebellion' generally means the revolt of the Long Parliament against the authority of Charles I. (q.v.). See also CROMWELL, FALKLAND, HAMPTON, &c.; ENGLAND; and the works of S. R. Gardiner. The revolts on behalf of the House of Stuart in 1715 and 1745 are often, particularly in Scotland, spoken of emphatically as 'The Rebellion' (see JACOBITES). The term is applied to the events in Ireland in 1798 and 1916, and in the United States to the secession of the southern states.

Rebus, an enigmatical representation of a name or thing by using pictorial devices for letters, syllables, or parts of words—*non verbis sed rebus*. Devices of this kind, allusive to the bearer's name, were common in the middle ages, particularly in England; see BADGE.

Recall. See INITIATIVE AND REFERENDUM.

Récamiér, MADAME (*née* JEANNE FRANÇOISE JULIE ADELAÏDE BERNARD), a famous Frenchwoman, was born at Lyons, 4th December 1777. She grew up a girl of remarkable grace and beauty, and at fifteen she was married to M. Jacques Récamiér, a rich banker about thrice her own age. Her salon was soon filled with the brightest wits of the literary and political circles of the day, but fortunately for herself Madame Récamiér possessed a temperament that saved her from temptation and almost scandal. For Madame de Staël she had a warm affection that survived the exile required by the jealousy of Napoleon. Soon after this her husband was completely ruined, and Madame Récamiér visited Madame de Staël at Coppet in Switzerland (1806). Here she met Prince August of Prussia, who alone of all her innumerable admirers is supposed to have touched her heart. Indeed a marriage was arranged, provided M. Récamiér would consent to a divorce. The good man did not refuse, but his kindness was too much for the generous heart of Madame Récamiér, who declared she could not leave him in his adversity. The most distinguished friend of her later years was M. de Chateaubriand. In 1846 he became a widower, and he then wished to marry Madame Récamiér, whose husband had been dead since 1830, but the lady declined the honour without interrupting the current of their friendship. Chateaubriand died 4th July 1848, and she followed him to the grave on 11th May 1849.

Recanati, a town of Italy, 15 miles S. of Ancona, has a Gothic cathedral with a monument to Pope Gregory XII. (who died here) and some fine Renaissance buildings. Here Leopardi was

born. Pop. 16,000. Porto Recanati, 6 miles NE. on the Adriatic coast, has a pop. of 5000.

Receipt is the technical as well as popular term signifying a legal acknowledgment of money received in discharge of a debt or demand. In England it is often believed that a written receipt is the only legal proof of payment; the fact being that it is only one mode of proving it. If the money be paid in presence of witnesses, or even without witnesses, provided a jury or judge believe the statement on oath of the party paying it, this is in England quite as good evidence of the payment as if a written receipt were given; and even a written receipt is conclusive only where it is under seal, or endorsed on a conveyance under the Conveyancing Act of 1881, unless the purchaser had notice to the contrary, or on a marine policy between assured and underwriter. In other cases a receipt is only *prima facie* evidence, and may be explained. If a receipt (except for salary, &c.) is in writing and the sum paid is 40s. or more, it must be stamped with a 2d. receipt-stamp (which may be an adhesive stamp), to be cancelled before delivery, otherwise the receipt is inadmissible as evidence of payment; but on payment of certain penalties the receipt may be after-stamped with an impressed stamp. Not only is a receipt proper subject to stamp-duty, but also any note or memorandum given to a person on payment of money, and acknowledging payment of any part of a debt or demand, whether signed or not; so receipts given on payment of bills of exchange or promissory-notes are liable to stamp-duty. But a mere acknowledgment of indebtedness, as a receipt 'on loan,' or an I O U, is not stampable as a receipt. There are several exceptions from liability to stamp-duty. Such are receipts for deposits with bankers to be accounted for; receipts for any parliamentary taxes or duties, or for any payment to the Sovereign; receipts by officers, seamen, marines, or soldiers for wages or pay; receipts for purchase of government stock or for money due under Exchequer Bill; receipts written on any bill or note of the Bank of England or of Ireland, on the back of duly stamped bills of exchange or promissory-notes, or upon the back of duly stamped instruments acknowledging the receipt of money; and generally receipts to or by government departments. At one time, under the Act of 1803, it was supposed to be the duty of the debtor to provide stamped paper for a receipt, the creditor being liable in a penalty of £10 if he refused to sign. This act, however, is repealed, and the better view is that when the debtor tenders payment the creditor is bound to give a proper discharge, its form being regulated by custom. In Scotland the receipt of money cannot be proved by witnesses where the debt was created by writing, and it is not allowed to dispute the validity of a written receipt duly delivered except in cases of fraud. It is only in the case of ready-money sales that receipt of the price can be proved by parole. See *Alpe's Law of Stamp Duties* (18th ed. 1925).

Receiving Stolen Goods. See **THEFT**.

Recent Period. See **POSTGLACIAL AND RECENT SYSTEM**.

Rechabites, members of one of those Friendly Societies (q.v.) which make total abstinence (see *Jer. xxxv. 6*) a fundamental principle.

Recidivists is a modification of the French term for habitual criminals, many of whom have been sent to Cayenne and New Caledonia.

Recife. See **PERNAMBUCO**.

Reciprocity, in Political Economy, a term for an arrangement between two countries having a protective tariff against other countries, to admit

each from the other's territories certain specified taxable articles of commerce duty-free or at exceptionally light duties. The classes of articles are arranged to balance one another on one side and the other. Such mutual arrangements are sometimes called Fair Trade as opposed to Free Trade (q.v.) and thoroughgoing Protection (q.v.), and have been advocated for Britain and her colonies.

Recitative. See **MUSIC, OPERA**.

Reclamation. See **WASTE LANDS, BOG, &c.**

Reclus, JEAN JACQUES ÉLISÉE, geographer, was born at Sainte-Foix la Grande (Gironde) on 15th March 1830, and educated at Montauban and under Carl Ritter at Berlin. In consequence of his extreme democratic views he left France after the *coup d'état* of 1851, and spent the next seven years in England, Ireland, North and Central America, and Colombia. He returned to Paris in 1858, and published *Voyage à la Sierra Nevada de Sainte-Marthe* (1861). For his share in the Commune (1871) he was banished, but returned in 1879; and from 1893 he was a professor at Brussels. He died 5th July 1905. His masterpiece was the *Nouvelle Géographie Universelle* (19 vols. 1876-94). Other works were *La Terre* (1867-68), *Histoire d'un Russeau* (1866), *Les Phénomènes Terrestres* (1873), *Histoire d'une Montagne* (1880), and *L'Idéal Éclaircique* (1903).—His elder brother, MICHEL ÉLIE RECLUS (1827-1904), was also an anarchist, a geographer, and a professor at Brussels, and wrote on the natives of Australia.

Recluse. See **ASCETICISM, HERMIT, MONACHISM**.

Recognisance is a kind of judicial bond entered into with a court of record, the object of which is to secure the doing of some act, as the appearance of witnesses at a criminal trial, or the keeping of the peace by one who has threatened or assaulted another. The form of it is thus: 'A B doth acknowledge to owe to our lord the King the sum of ten pounds,' or some other sum, to be levied of his goods if he fail in the condition endorsed; and then a condition is added, which states that, if the thing secured is done, then the recognisance is to be void. This is the mode by which justices of the peace secure the attendance of the prosecutor and witnesses at the trial of a prisoner who has been committed for trial, or the future good behaviour of one who has committed a breach of the peace. If the thing secured is not performed, then the recognisance is estreated—i.e. extracted and put in force, a debt of the amount specified being forthwith due to the crown. In Scotland, the place of recognisances is filled by cautions; a caution in law burrows corresponds very nearly to a recognisance to keep the peace (see **CAUTION**). In the United States recognisances are used for much the same purposes as in England.

Recoil. See **CANNON, MONCRIEFF**.

Recollet (Lat. *recollectus*, 'gathered together'). See **FRANCISCANS**.

Record, as a legal term, is used in the United Kingdom to signify anything entered in the rolls of a court, and especially the formal statements or pleadings of parties in a litigation. In general the rule is well settled that the pleadings which make up the record do not enter into details of the evidence, but merely set forth the conclusions or inferences, leaving the details of evidence to be supplied at the trial before a jury, or, if there is no jury, at the hearing before the judge or court. One of the incidents of a Court of Record is that the court or judge can commit for contempt any person who insults the court or wilfully obstructs the business. A trial by record means that one

of the parties has set up some former decision of the court, while the other denies that such a decision ever existed; whereupon the only mode of solving the question is by producing the record of the former action, and so settling the dispute. In Scotland the closing of the record is a step which requires the sanction of the judge, who closes the record after each party has said all he wishes to say by way of statement and answer.

Recorder, ROBERT, mathematician, was born about 1510 at Tenby. He studied at Oxford, but, wishing to make medicine his profession, removed to Cambridge, where in 1545 he received the degree of M.D. In 1547 he was in London, engaged in the composition of *The Urinal of Physic* (1548), and was about the same time appointed physician to Edward VI., as afterwards to Queen Mary. Ten years later he died miserably in the debtors' prison in London. His works, in the form of dialogues between a master and his pupil, and written in the rude English of his time, are *The Grounde of Artes, teaching the Perfect Work and Practice of Arithmetike* (1543); *The Pathway to Knowledge* (1551), an abridgment of Euclid's *Elements*; *The Castle of Knowledge, containing the Explication of the Sphere both Celestial and Material*, (1551), an astronomical work, in which he compares the Ptolemaic and Copernican systems; *The Whetstone of Wit* (1557), a treatise upon algebra. In the appreciation of the general results derivable from algebraic formulae he is far beyond his contemporaries, with the sole exception of Vieta (q.v.).

Recorder is a judge of a city or borough court of quarter sessions. He must be a barrister of not less than five years' standing, is appointed by the crown, holds office during good behaviour, and the salary is paid by the city or borough out of the borough fund. He sits as sole judge of the court of quarter sessions for his district, but he cannot grant licenses or be an official in licensing matters, or order rates to be levied. The recorder is not prohibited from practising at the bar, and indeed his salary is usually small. He can appoint as deputy, in case of necessity, a barrister of five years' standing, and, if need be, an assistant-recorder. In London he is elected by the Lord Mayor and aldermen, and as 'monthpiece of the city' he certifies the customs of London. He is chief judge in the Mayor's Court of London, and is one of the judges sitting at the Central Criminal Court, commonly called the Old Bailey. Among the many well-known men who have held this post were Lord Coke and Lord-chancellor Jeffreys. There is no such office in Scotland, but the sheriff discharges similar duties.

Recorder, the name of an old musical instrument something like a flageolet, but with the lower part wider than the upper, and a monthpiece resembling the beak of a bird.

Records, PUBLIC (Lat. *recordari*, 'to remember'), may be described as contemporary statements of acts and proceedings in public affairs, officially authenticated and preserved in the public interest. The technical application of the term in England is fixed by the Public Record Office Act of 1838, and an Order in Council of 1852. The act included 'all rolls, records, writs, books, proceedings, decrees, bills, warrants, accounts, papers and documents whatsoever of a public nature belonging to Her Majesty,' and deposited in certain specified places. In effect the Master of the Rolls became custodian of the whole body of legal records. The Order in Council brought all departmental and state papers 'under the charge and superintendence' of the Master of the Rolls, though not actually into his 'custody.' By a working compromise the depart-

ments retain the power of regulating access to their documents.

In 1800 a select committee reported upon the state of the public records; but up till 1836 nothing practical was done to remedy the defect that they were scattered in various repositories, not very suitable and sometimes dangerous, such as the Tower, the Chapter House at Westminster, and the Rolls House and Chapel, and that they were under no general charge. The Select Committee of 1836 insisted upon the importance of 'proper custody,' and recommended the erection of a Record Office. In 1851 the present Public Record Office in Fetter Lane was begun. In 1900 it was finished; but extension will soon be necessary.

Though the report of 1800 did not immediately lead to reform in the matter of custody, or effective steps towards reducing the records to order, there was some activity in publication. Before the Public Record Office Act of 1838, various Record Commissions and the State Paper Commission issued more than 100 volumes. About 1856 the printing of national documents came under the superintendence of the Master of the Rolls, and the field of operations was enlarged in the interests of historical research. Calendars of Domestic, Colonial, and Foreign State Papers were successively undertaken. Materials relating to British history in the continental archives were examined and prepared for publication; at home recourse was had to various libraries, such as the British Museum or the Bodleian. In the 'Rolls Series,' which extends to more than 250 volumes, matter was derived from sources outside the Record Office; but, as these publications tended to divert energy from what lay within the office, practically no new work in the series was undertaken after 1886. The policy of issuing calendars of State Papers was pursued; and, in order to compensate for the termination of the Rolls Series, calendars of medieval records were begun. In 1890 'Record Office Lists and Indexes' were announced. This series, with the calendars, was intended to 'constitute a general catalogue of the contents of the Public Record Office.' The purpose of calendars is to make the contents of documents sufficiently accessible for ordinary reference, and to obviate the necessity of recourse to the original. In this respect a mere catalogue of documents is obviously deficient. The practical problem is to hit the mean between an excessively full, and therefore slowly executed, calendar, and a bare list which fails to indicate the nature of the subject-matter.

By the Act of 1838 the Master of the Rolls became responsible head of the Record Office Department; as, however, he had to attend to the business of his own special court, a Deputy-keeper of the Records was appointed to conduct administration and publication. When the Master of the Rolls became President of the Court of Appeal, he continued to be responsible keeper, but his deputy, in theory a subordinate official, assumed in practice the control of the Record Office. Though the Select Committee of 1836 did not recommend that the functions of preserving and publishing the archives should be permanently combined in one hand, the actual development since the Act of 1838 has, in this respect, differentiated English usage from continental.

The records under the superintendence of the Master of the Rolls include those (1) of the Courts of Chancery, King's Bench, Common Pleas and Exchequer; (2) of Special and Abolished Jurisdictions, such as the Marshalsea and Palace Courts, the Courts of Requests, Star Chamber, and Wards and Liveries; (3) of the High Court of Admiralty; (4) of the Palatinate of Durham; and (5) the

Palatinate of Lancaster; (6) of the Principality of Wales, with those of the Palatinate of Chester; (7) of the Duchy of Lancaster; (8) the State Papers, domestic, colonial, and foreign, formerly in the State Paper Office at Westminster, which was merged in the Record Office in 1854; (9) the records of the Government Departments; and (10) records of Abolished Offices and Expired Commissions of Enquiry.

Since 1890 much has been effected under Sir H. Maxwell Lyte, as deputy-keeper, to classify the contents of the Record Office, and make them accessible to the public. The first *Handbook to the Public Records*, published in 1853 by F. S. Thomas, was superseded by a *Guide to the Public Records*, compiled by S. R. Scargill-Bird (3d ed. 1908). Lists of Record Publications, printed by the Stationery Office, were inserted in each volume issued. H. Hall's *Studies in English Official Historical Documents* (1908), *Formula Book of Diplomatic Documents* (1908), *Formula Book of Legal Records* (1909) were important for the student.

A Commission on Public Records (England and Wales) was appointed in 1910, and the three Reports (1912-19) contain a great mass of statistical and historical information. It is stated that 'nowhere is the concentration of all public records and state papers in a single repository carried to the same extent as it is in England,' and that, abroad, 'the practical difficulties which might result from the division of the public records amongst a number of repositories are met by centralising the administration of the archives, instead of centralising the documents themselves.' The existence of provincial offices, the technical training required of archivists, and the scientific classification of documents, are held to assist historical education and encourage the study of local history.

During recent years the study of records as historical sources has been developed at the universities, notably at Manchester, Oxford, and London. This interest, represented in the 1910 Commission, has led to several publications, official and unofficial, since the Great War. A new *Guide to the Public Records* (2 vols., 1923-24) has been compiled by M. S. Giuseppe. The Royal Historical Society produced in 1920 a *Repertory of British Archives (England)*, by H. Hall, which contains a valuable historical introduction and surveys the local records. In 1925 the same author issued *British Archives and the Sources for the History of the World War*.

The Historical MSS. Commission was appointed in 1869 to describe the contents of private or semi-public local records of the United Kingdom. An account of the work will be found in the *Transactions of the Royal Historical Society* (3d series, vol. iv.). Some of the documents inspected are in the Public Record Office, of which the Commission acts almost as a branch; but it has reported upon very many local collections of records, which may be classified as (a) public, (b) semi-public, and (c) private. In spite of the centralising tendency in England, already noted, there is of course a great mass of local records which are of a public character. For example, we have (1) civil records, both administrative and judicial, such as those of counties and municipalities, and (2) ecclesiastical records, notably the old parish registers. Full information on this subject will be found in the Report of the Local Records Committee (1902), which contains matter relating also to Scotland and Ireland, and in Hall's *Repertory of British Archives*. Useful aids in consulting the Historical MSS. Reports are the *Topographical Guide* and the lists in Report XVII., both issued by the Commission.

Students desiring to work at the Public Record

Office must apply for tickets, as in the case of the British Museum. Access to the records of Government Departments, which are not in the 'custody' of the Master of the Rolls, is not uniformly regulated, and depends upon the departmental authority. In certain cases a permit is necessary.

Scotland.—An inventory of 1282 gives a list of some of the writs deposited in the King's treasury at Edinburgh. Edward I. removed from the Castle those affecting the contested succession (1291), and subsequently transferred them from Berwick to Westminster. Documents bearing upon the administration did not elude his grasp, and found their way to London, where such of these early Scottish records as survive are still retained. Another misfortune occurred in the Commonwealth period. Cromwell possessed himself of the national records on the surrender of Stirling Castle (1651). The Register of the Privy Seal, however, escaped capture. The books were carried for concealment to the Highlands, and were returned to public custody only in 1707. In 1657 no fewer than 1547 volumes relating to private rights were sent back to Edinburgh. On the Restoration the *Eagle* frigate was ordered to transport the rest of the captured records to Leith. The greater part of the cargo, however, was put on board a merchant ship at Yarmouth, and went down with her. The exact extent of the loss is not known, and may be exaggerated; but important ecclesiastical records, taken from the Bass (1652) and sent to London, may have been involved in the disaster. Additional particulars regarding these vicissitudes will be found in the published Acts of the Scottish Parliament (*v. Index*, under 'Records'), General Assembly Reports (1889), the official handbook mentioned below, and Thomson's lectures on *The Public Records of Scotland* (1922).

After the Restoration the records ceased to be preserved in Edinburgh Castle, and were deposited in the Laigh Parliament House, where they suffered from damp and neglect. Some of the hog-heads returned from London were not unpacked for almost a century. The absence of a suitable repository, and the practice of keeping registers in the private houses of clerks, account for some additional losses. The project of a Register House, taken up in 1765, was realised some twenty years later, and the building was gradually completed after the designs of Robert Adam.

The development in Scotland from the time of Alexander III., when we hear of a 'Clerk of the Rolls of the King's Chapel,' tended to place the national archives in the charge of a single official. The Lord Clerk-Register, as he was ultimately styled, came to be concerned *ex officio* with the proceedings of Parliament, Privy Council, Court of Session, and Court of Exchequer; his custody was also extended to registers relating to private rights. By an Act of 1879 the Lord Clerk-Register's duties were practically confined to the process of electing the representative peers, and the Deputy-Clerk-Register became Keeper of the Records. This official also exercised the function of Registrar-General, and a Deputy-keeper of the Records acted under him in the administration of the Record Office. At present the office of Deputy-Clerk-Register has been for some years vacant, and there is no properly constituted Record authority.

The tendency towards centralisation has prevailed in Scotland. Any detailed account of the records at present deposited in the Register House is rendered unnecessary by a *Guide to the Public Records of Scotland* (1905), by M. Livingstone, late Deputy-keeper. This book not only gives a classification and inventory of the various registers and collections preserved there, but also contains much information relating to their history and contents.

It is important to note that an appendix to the volume gives some account of certain records which are retained in departmental custody, such as those of the Court of Teinds and the Lyon Court, or Court of Arms. In the office of H.M. Chancery is retained the record of Retours, or returns made by juries proceeding upon briefs or royal warrants, the great majority of which are verdicts serving heirs to their ancestors. It is believed that the earlier records of Chancery were destroyed at Holyrood in Hertford's invasion (1544). The Services of Heirs from 1545 to 1700 were abridged and printed (1811); from 1700 to 1859 there is a printed index arranged by decades. Another important class of records not deposited with the Keeper of the Records are those of the High Court of Justiciary, and no description of them will be found in the handbook. For an explanatory account of the Scottish Records, based upon unique knowledge, the reader should consult Maitland Thomson's lectures, already mentioned.

Of the records in charge of the Deputy-Clerk-Register, the first class relates to the Crown, Parliament (to 1707), Revenue, and Administration. The Judicial records, secondly, comprise those connected with the Session as supreme civil court, and include the important Register of Deeds. Books and papers of the old episcopal or Commissary Courts, involving the valuable registers of Testaments, were fortunately brought in for preservation. There are also deposited many records of defunct local and heritable jurisdictions. Under the third head of titles to land, dignities, and offices, besides the Registers of the Great Seal (from 1306) and the Privy Seal (from 1488), there is the Register of Sasines, which extends to more than 20,000 volumes, and records the formal transfer of land to new proprietors. This register was fairly established in 1617, after more than half a century of experiment. There is also a valuable collection of original charters, calendared and indexed nearly to the end of the 16th century, and a number of protocol books, in which notaries recorded their official acts. The Burgh Registers of Sasines (from 1681) are an exception to the complete centralisation of land records. A fourth and miscellaneous class of books and documents contains certain important ecclesiastical records. The extant parochial registers, in the charge of the Registrar-General, are in the New Register House.

Publication of the Scottish Records was begun early in the 19th century, and more than 115 volumes have been issued; but there is also much information accessible in the English calendars, the Reports of the Historical MSS. Commission ('Index,' by Terry, 1908), and the various historical club books ('Catalogue,' by Terry, 1909). The Report of the Committee on Local Records (1902) contains returns for Scotland. The public records in local custody include not only the Burgh Registers of Sasines already mentioned, but the more important Sheriff Court Records. A Committee (1925) recommended that the latter should be centralised for preservation and accessibility.

Historical students who desire to prosecute researches in the Record Office must satisfy the Keeper of the Records in order to obtain a free permit.

Ireland.—Many records perished during the wars of conquest. A Record Commission, appointed in 1810, continued till 1830, and did much for the preservation and arrangement of the Irish archives. After a new Commission in 1848 a bill for proper custody was drafted, but was not carried. The public records were kept by several persons and often in unsuitable places; but a Record Office was ultimately established, and a Public Records (Ireland) Act was passed in 1867, in many respects based on the English Act of 1838. The Master

of the Rolls in Ireland took charge of records relating to the Chancery, Common Law, Probate, Admiralty, and Prerogative Courts, records in the Dublin Customs House, original wills, various rolls and parliamentary records, State Papers of the age of fifty years and upwards, and documents of defunct courts, commissions, and offices. Certain county records were included under powers conferred by the Act upon the Lord-lieutenant in Council. Most of the parochial registers of the Disestablished Irish Church were transmitted; but centralisation was unfortunately not compulsory, and some confusion resulted. As in Scotland, the local records which remained outside the capital were relatively fewer than those which are preserved locally in England. In 1919 a *Guide to the Public Records of Ireland* (H. Wood) was issued, with an introductory historical sketch.

Among the English Record Publications are a number of calendars relating to Ireland. There are also Irish Record Publications. The regular Reports of the Deputy-keeper (from 1869) contain calendars, lists, and indexes. These issues, with the Reports of the Historical MSS. Commission and volumes in the Rolls Series, are included in the general catalogue appended to the English Record Publications as they appear.

In June 1922 a great disaster befel the Irish Records in the destruction of the Four Courts in Dublin. Northern Ireland made a separate office for the custody of its records, as there was no repository in Dublin, even if political conditions had permitted a common centre. In his First Report (1924) the Deputy-keeper for Northern Ireland stated that, in view of the enormous destruction in Dublin, efforts were made to obtain copies from every possible source, and that one of the worst losses, viz. original wills, had been partially repaired.

Colonial and Foreign.—Information regarding continental systems appears in the *Reports of the English Commission* (1910). A recent and exceedingly useful review of record systems is due to the enlightened action of the South African Government. A report (C. G. Botha: Pretoria, 1921) contains an interesting comparative study dealing with practical questions, and a list which includes publications relating to records in Canada and the United States.

Recovery. See **ENTAIL**.

Recruit. See **ENLISTMENT, ARMY**.

Rectifying is a process applied to alcohol, chloroform, or other volatile liquid, by which the last traces of impurities are removed by distillation. Many varieties of stills and condensers have been devised for this purpose, for further reference to which see **DISTILLATION**, and **ALCOHOL**.

Rector (Lat. 'ruler'), in the Church of England, is a clergyman who has the charge and cure of a parish where the tithes are not inappropriate, and who accordingly has the whole right to the ecclesiastical dues therein; where the tithes are inappropriate the parson is a Vicar (q.v.). In the Episcopal Churches of the United States and (since 1890) Scotland all incumbents are called rectors. See also **EDUCATION**, and **UNIVERSITIES**.

Rectum, the terminal portion of the intestinal canal, named, from its comparatively straight course, the rectum (see **DIGESTION**), is the seat of various affections requiring medical or surgical assistance. Some of these affections, as fistula, fissure (see **ANUS**), piles, prolapsus ani, have already been considered. Amongst the other diseases of the rectum of sufficient importance to claim notice in these pages are—

(1) *Stricture of the Rectum*, which may be either of a simple or malignant nature. *Simple stricture*

consists in a thickening and induration of the sub-mucous tissue, less often of the muscular or mucous coat of the rectum, so as to form a ring encroaching on the calibre of the tube. It may occur as the result of injury or operation, of old ulceration (e.g. from dysentery), of syphilis, or without ascertainable cause. The symptoms are constipation and great pain, and a straining in evacuating the faeces, which, if not liquid, are passed in a narrow, flattened, or worm-like form that is very significant of the nature of the case. In an advanced stage of the disease diarrhoea often supervenes. However great may be the constipation, strong purgatives must be altogether avoided. Soft and unobnoxious evacuations must be procured by such medicines as the confection of senna combined with sulphur (see PILES), or by slines, which make the intestinal contents more fluid, or injections of castor-oil or of tepid water. The diet should be regulated so as to assist the action of the medicines. Gradual dilatation by suitable bougies often gives great relief, but must be steadily persevered with, as the contraction is almost certain to recur. *Malignant stricture*—most commonly due to the scirrhus, but sometimes to the epithelial form of cancer—is by no means a very rare affection. Until ulceration sets in the symptoms are like those of simple stricture, only exaggerated in degree; but afterwards there is a discharge of fetid muco-purulent matter streaked with blood. In this disease the treatment can, in most cases, be only palliative. Sometimes, however, if the tumour is low down and localised it may be removed with at least temporary relief. If complete obstruction occur, or is threatened, the surgeon may resort to the formation of an artificial anus in the groin, which not only may prolong life for several years, but leads to great relief in the symptoms of the tumour, which is no longer irritated by the faeces.

(2) *Spasm of the sphincter ani* muscle is characterised by extreme pain in the region of the anus, especially when an attempt is made to evacuate the bowels. The muscle contracts so firmly that the surgeon cannot easily introduce the finger into the rectum. The spasm may be caused by piles, especially by fissure of the anus, by ulceration of the rectum, and sometimes apparently by mere constipation. It is often relieved by the application of belladonna ointment or by a simple operation.

(3) *Neuralgia of the rectum*, known also as *proctalgia*, is sometimes met with, and is especially prone to attack children and gouty persons. It is usually relieved by the judicious use of aperient medicines and such treatment as is used for other forms of Neuralgia (q.v.).

(4) *Pruritus ani*, or *itching of the anus*, is a very common and extremely troublesome affection. Sometimes it depends on the presence of thread-worms, of old piles, constipation, or some other local cause of irritation, while in other cases it is one of the manifestations of some constitutional condition. The treatment must depend upon the exciting cause, but for this condition suppositories of zinc oxide and cocoa butter in equal parts are especially soothing.

Reculver, a village on the coast of Kent, 9 miles W. of Margate, with remains of the Roman station *Regulbium*.

Recusants, persons who refused or neglected to attend at the worship of the established church on Sundays and other days appointed for the purpose. The offence as a legal one may be held to date from 1 Elizabeth, chap. 2; but there were four classes punishable under the statutes against recusancy—simple 'recusants'; 'recusants convict,' who

absented themselves after conviction; 'popish recusants,' who absented themselves because of their being Roman Catholics; and 'popish recusants convict,' who absented themselves after conviction. Protestant dissenting recusants were relieved from the penalties of recusancy by the Toleration Act of 1 Will. and Mary, chap. 18. Catholics were partially relieved in the year 1791, and completely by the Emancipation Act of 1829.

Red. Most of the important red pigments are separately noticed. For carmine and crimson lake prepared from cochineal, and also for the madder reds, see LAKES. The reds of which oxide of iron is the colouring ingredient—viz. Indian red, Venetian red, and light red—are referred to under OCHRES. Vermilion (q.v.) is one of the finest and most beautiful reds, though not always so permanent, at least as a water-colour pigment, as was formerly supposed. For house-painters' use this colour is often adulterated with red lead, which, though forming a useful paint for some common purposes, is fugitive. See also DYEING.

Redan. See FORTIFICATION, SEBASTOPOL.

Redbreast (*Erithacus rubecula*), a bird of the family Sylviidae, well known in the British Isles because of its very general distribution, its early and legendary associations, its conspicuous plumage, and the fact of its being resident. Its range is gradually extending northwards, and now it is found breeding in the Hebrides and Orkneys; in spring it is found on the island of Jan Mayen, in autumn it visits the Faeroes. Southwards it breeds throughout Europe (but only locally in the south of Spain), in North-west Africa and the Canaries, Madeira, and the Azores; eastwards to the Ural Mountains. In winter its migrations extend to the Sahara, Egypt, Palestine, and Persia. The redbreast, known familiarly as Robin or Robin Redbreast, is about 5½ inches long, olive-brown in colour on the upper parts; chin, throat, and upper breast reddish orange, bordered with bluish gray on the sides of the neck and shoulders; under parts dull white; bill black; legs and feet brown; the body fairly full and round, the legs slender. The female is usually but not always duller than the male. In habit robins are domineering and pugnacious; solitary, or found only in pairs, preferring plantations, but coming near dwelling-houses when forced by severe weather. Nesting begins in March. The nest of dead leaves, dried grass and moss, lined with hair and feathers, is made in banks, hollow trees, and sometimes in strange and extraordinary places. The eggs, five to seven, are usually white with light reddish blotches, or pure white. Two or three broods are produced in the season. In autumn the young are forced by their parents to migrate, and at this season there is generally a great influx of robins from the northern parts of the Continent, where they have been passing the summer. The food consists chiefly of insects and worms; often of berries and other fruits; and in winter bread-crumbs and scraps of meat. Its song is sweet and plaintive, but of little compass, and not much noticed when other songsters abound. The widely distributed robin of the United States and Canada is a Thrush (*Turdus migratorius*).

Redcar, a popular bathing-resort in the North Riding of Yorkshire, 10 miles by rail N.E. of Middlesbrough. Its smooth, firm sands stretch 10 miles from the mouth of the Tees to Saltburn. Pop. (1921) 16,399.

Red Cedar. See JUNIPER.

Red Clay. See SEA.

Red Crag. See PLEISTOCENE SYSTEM.

Red Cross, THE, is the badge and flag adopted by every society, of whatever nation, formed for

the aid of the sick and wounded in time of war, recognised and authorised by the military authorities of its own nation, and enjoying certain privileges and immunities under the treaty known as the Convention of Geneva. Hence 'Red Cross Society' has become a generic name for all such voluntary efforts, and cannot be monopolised by any one of them. For three centuries and more a medical service has been attached to armies, and was long thought sufficient for every emergency, but the revelations made during the Crimean war (1853-56) were terrible. The merciful mission of Florence Nightingale and her companions, while reducing the losses by one-half, threw light upon shocking defects, and compelled the acknowledgment of want of organisation in everything connected with the health of the troops and care of the wounded. Nevertheless, when war broke out in Lombardy (1859) similar inefficiency was apparent. Loud complaints arose, but the first practical result ensued from the publication by M. Dunant of his *Souvenir de Solferino*. The account of this battle (June 24, 1859), which lasted fifteen hours and in which 300,000 combatants were engaged, was so heart-rending as to force public attention to the necessity for supplementing the medical and sanitary service by volunteer societies trained and organised in time of peace. The book was discussed at Geneva at a meeting of the *Société Générale d'Utilité Publique*, February 9, 1863, a date which may be taken as the starting-point of the Red Cross. An international conference assembled at Geneva, October 26, 1863, and included among its thirty-six members delegates from fourteen governments and six associations. The main recommendations agreed to were (1) the formation in each country of a committee to co-operate with the army sanitary service in communication with the government, and occupying itself in time of peace with preparing supplies of hospital stores, training nurses, &c., and during war furnishing the same in aid of their respective armies, neutral nations being invited to assist such national committees; (2) the declaration of the neutrality of hospitals, of the officials of the sanitary service, of the unpaid nurses, of the inhabitants of the country aiding the wounded, and even of the wounded themselves. The conference suggested the adoption of the same distinctive and uniform badge (the red cross on a white ground) for all hospitals and sanitary officials as well as for the volunteer relief agents. A treaty, the Convention of Geneva, embodying these resolutions was signed at a second conference at Geneva in 1864 by twelve out of sixteen representatives there assembled, and it has since been acceded to by every civilised nation. International conferences have been held at Paris (when the convention was extended to naval warfare), Berlin, and Vienna, but the resolutions passed at Geneva have undergone no material alteration. By the Covenant of the League of Nations 'The members of the League agree to encourage and promote the establishment and co-operation of duly authorised voluntary national Red Cross organisations having as purposes the improvement of health, the prevention of disease, and the mitigation of suffering throughout the world.' (Art. xxv.) For some years prior to the Great War the British Red Cross Society and the Order of St John (see HOSPITALIERS) had occupied themselves in the training of Voluntary Aid Detachments throughout the country, primarily for service with the territorial force in time of need. During the Great War, however, these became a vital part of the general Red Cross organisation, and did valuable work in all branches of the army at home and abroad. The two British organisations were for wartime purposes directed by a joint-committee, which

co-ordinated their services, and which was continued after the declaration of peace in order to facilitate the work proposed by the League of Nations.

See an American book by Davison (1920); A. de Lisle, *The Story of the Red Cross* (1905); a series of articles in the *Times*, September 24-29, 1917; and Hall, *International Law* (1924).

Red Cross, THE ROYAL. This decoration was instituted by Queen Victoria in 1883. It is conferred on any ladies, English or foreign, recommended by the Secretary of State for War, for special exertions in providing for the nursing, or for attending to sick and wounded soldiers and sailors. The decoration is a cross of crimson enamel gold-edged, attached to a dark-blue ribbon red-edged, one inch in width, tied in a bow and worn on the left shoulder.

Red Deer, or STAG (*Cervus elaphus*), a large and very handsome animal, inhabiting some of the forests of Europe, West Asia, and North Africa. Those living in the more northern parts are smaller. In Britain red deer are found on Exmoor, in the Highlands of Scotland, and in some parts of Ireland.

Stag, Hind, and Calf (*Cervus elaphus*).

The full-grown animal stands over 4 feet at the withers, and is dark reddish brown in colour, slightly grayish in winter. The antlers (q.v.), with which the rival males fight, belong to what is called the elaphine type, having protrusive brow-tines, well-marked bez-tines, a rounded beam, and terminal snags 'arranged in a cup or crown.' As usual, they are shed in the spring of each year, and gain 'points' with each year's fresh growth, a 'royal stag' having twelve, though this is not the maximum. Darwin mentions an antler 30 inches in length with fifteen snags, and another with thirty-three, while Flower refers to 'a pair of antlers, weighing 74 lb., and with forty-five points.'

The male stags are distinguished by the possession of antlers, and are rather larger and stronger than the females. Their voice is also stronger, for they bellow very loudly when enraged or when challenging their rivals. The combats are very fierce, and sometimes fatal even to both combatants, for their antlers sometimes interlock inextricably. In fighting, the projecting brow-tines form most effective weapons. The breeding season is in September or October, but the young are not born till the end of May or the beginning of June. As in most species of *Cervus* they are first slightly spotted with white. In the first year the young male has only a hint of antlers, in the second year

only small unbranched beams; thereafter a tine is gained each year. Nearly allied is the North American Wapiti (*C. canadensis*), and there are closely related species or varieties in Persia, Kashmir, and Tibet. Scottish red deer—the poorest breed in Europe, as the animal is naturally a woodland deer—have of late been successfully crossed with Canadian and Asiatic Wapiti.

See DEER, DEER FORESTS, STAG-HOUND; *Red Deer*, by Jeffries (1884); *The Red Deer*, by Macpherson and others (1896); and Winans, *Deer-breeding for Time Heats* (1913).

Redditch, a town on the borders of Worcester and Warwick shires, on an acclivity 13 miles SSW. of Birmingham, makes needles, pins, fish-hooks, fishing-tackle, motor-cycles, cycles, and springs. Pop. (1851) 4802; (1911) 15,463; (1921) 16,231.

Reddle, **RADULE**, or **RED CHALK** (Scot. *keel*), an impure peroxide of iron (ferric oxide) associated with very variable proportions of clay or chalk, or sometimes other substances. It varies greatly too in hardness, some kinds being difficult to crush and others quite soft. In colour it passes from a pale brick-red to a tint occasionally nearly as bright as vermillion. It is found in many places abroad, and in England in Somersetshire, the Forest of Dean, at Watwaster in Cumberland, and, of a quality valuable for polishing optical glasses, near Rotherham in Yorkshire. Some kinds of it are used for marking sheep, others for carpenters' and masons' pencils, and the finer qualities for artists' crayons. Red ochre is one of the varieties.

Red Earth, the name given to the reddish loam or earth which so frequently occurs in regions composed of limestones. This earth is the insoluble residue of those portions of the calcareous rock which have been dissolved by rain. Such red earths are of common occurrence in limestone caverns. See CAVE.

Redemptionists, one of the names of an order of monks devoted to the redemption of Christian captives from slavery. They are more frequently called Trinitarians (q.v.).

Redemptorists, called also LIGUORIANS, a congregation founded by St Alfonso Liguori (q.v.).

Redesdale, the valley of the river Reed in Northumberland, extending almost from the Scottish border in a south easterly direction for over 16 miles, until it opens up into the valley of the Tyne, the river joining the North Tyne at Reedsmouth. It is for miles a mere mountain vale, sloping upwards into bleak and dreary moorland, but it has a quiet beauty of its own that is not easily forgotten by the traveller. The river springs out of the Cheviot Hills, which lie athwart the head of the dale, and down its course from Carter Toll on the border lay one of the chief roads into England. Dere Street traverses it. Near the southern end of Redesdale is the famous field of Otterburn (q.v.), but 16 miles from the border, which point again is but 10 miles from Jedburgh. The men of Redesdale of old were brave and turbulent, and bore more than their share in Border feuds and forays.

Redeswire, **RAID OF THE**, a battle fought 7th July 1575 close to the English border at the pass leading across the Cheviots into Redesdale. A party of Scots was being beaten back and on the point of utter rout, when the provost and townsmen of Jedburgh arrived hot from the 10 miles' march, and at once set on the enemy. The Englishmen were soon completely defeated, with the loss of several considerable prisoners. There is a prosy ballad on the subject in Scott's *Border Minstrelsy*.

Red-eye, or **RUDD** (*Scardinius erythrophthalmus*), a fresh-water fish related to the Roach (q.v.), with which it may hybridise. It is common in

England and Ireland in lakes, slow rivers, and fens; and extends through Europe to Siberia. It

Red-eye or Rudd (*Scardinius erythrophthalmus*).

has a general coppery colour, with red fins and red iris, and may attain a length of 18 inches. Its flesh is not of much account.

Redgrave, **RICHARD**, painter, born in London on 30th April 1804, in 1826 was admitted a student of the Academy, and was elected an A.R.A. in 1840, an R.A. in 1851. From 1847 onwards he took a prominent part in art instruction, and in 1857 was appointed Inspector-general of Art Schools, which office, with that of Surveyor of the Royal Pictures, he resigned in 1880. In 1883 he ceased to exhibit. He wrote, with his brother, *A Century of English Painters* (1866), and edited several valuable catalogues. He died 14th December 1888. See *Memoir* by his daughter (1891).

Red-letter Days. See **BLACK LETTER**.

Redmond, **JOHN EDWARD**, Irish politician, was born of an old Catholic family of Wexford, at Dublin in 1857. He was educated at Clongowes Jesuit College, Trinity College, and King's Inn, Dublin, but in 1879 his father, member of parliament for Ballytrent, obtained for him a post as clerk in the vote office of the House of Commons. Two years later he entered parliament as the member for New Ross, becoming in 1885 member for N. Wexford, and in 1891 for Waterford. In the same year he assumed the leadership of the Parnellite party, and in 1900 that of the united Nationalist party. Until his death in London, 6th March 1918, he laboured unceasingly in the cause of Home Rule. See *IRELAND (History)*, and books by W. B. Wells (1919) and S. Gwynn (1919).

Redoubt. See **FORTIFICATION**.

Redout Kalé, a fortified post on the Black Sea coast of Georgia, is in a marshy region, about 10 miles N. of Poti. It was the chief shipping-place for Circassian girls to Turkey, and was captured by the British fleet in 1854.

Redpoll. See **LINNET**.

Red River, the lowest western branch of the Mississippi, rises near the eastern border of New Mexico, flows eastward through Texas, forming the entire southern boundary of Oklahoma, thence south-east through Arkansas and Louisiana, and enters the Mississippi below 31° N. lat. It is 1600 miles long, and receives numerous branches, the Washita (Ouachita) the most important. It is navigable for seven months to Shreveport (350 miles). A few miles above was formed the Great Raft, of driftwood, which blocked up the river.

Red River of the North, a navigable river of the United States and Canada, rises in Elbow Lake, Minnesota, near the sources of the Mississippi, and flows south and west to Breckinridge, then north, forming the boundary between Minnesota and North Dakota, and so into Manitoba and through a flat country to Lake Winnipeg. Its course is 665 miles (525 in the United States). The

Red River Settlement was the origin of Manitoba (q.v.). For the Red River Expedition, see CANADA and RIEL.

Red Root (*Ceanothus*), a genus of shrubs of the family Rhamnaceæ. The common Red Root of North America (*C. americanus*), which abounds from Canada to Florida, is a shrub of two to four feet high, with beautiful thyrsi of numerous small white flowers. *New Jersey Tea* is an infusion of its leaves, or of those of *C. ovatus* (Canada to Texas). A Mexican species (*C. azureus*) has blue flowers, and a Californian kind (*C. thyrsiflorus*) is used for evergreen hedges.

Redruth, a town of Cornwall, on a hillside (414 feet) in the centre of a great mining-district, 9 miles by rail W. by S. of Truro. It has a town-hall (1850), public rooms (1861), &c. William Murdoch (q.v.) here in 1792 first used gas for lighting purposes. Pop. 10,000.

Red Sea. The Red Sea is an arm of the Indian Ocean, running north-north-west from the Gulf of Aden, with which it communicates by the Strait of Bab-el-Mandeb, $13\frac{1}{2}$ miles across. Its length is about 1200 miles, and its width in the central portion is between 100 and 200 miles, the greatest breadth being about 250 miles; it narrows towards the southern entrance, while in the north it is divided by the peninsula of Sinai into two gulfs, the Gulf of Suez, 170 miles long by 30 miles wide, and the Gulf of 'Akaba, 100 miles in length.

The Arabian coasts of the Red Sea are usually narrow sandy plains backed by ranges of barren mountains; the African coasts towards the north are flat and sandy, but farther south high tablelands rise some distance inland, culminating still farther south in the lofty mountains of Abyssinia. A marked feature in the configuration of the Red Sea is found in the large existing and upraised coral-reefs running parallel to both the eastern and western shores, those to the east being more extensive and farther from the coast than those to the west; the most important are the Farisan Archipelago in the eastern reef, and the large island of Djulali, lying off Annesley Bay, in the western reef. In addition to the islands of organic formation mention may be made of the volcanic group lying in 14° N. lat., the largest of which, Jebel Zughr, is 10 miles long, 7 miles wide, and 2074 feet in height; farther north, on the islet of Jebel Teir is a volcano not very long extinct. A dangerous reef, the Dieldals, lies directly in the path of steamers in $24\frac{1}{2}^{\circ}$ N. lat., and a lighthouse has been placed on it. The principal harbours are Mocha, Hodeida, Lokkeyah, Jiddah, and Yenbo on the Arabian coast, Massana, Snakin, El Kosseir, and Port Sudan on the African coast.

In ancient times the Red Sea was used as a means of communication by the Phenicians and other maritime peoples, until the discovery of the route round the Cape of Good Hope diverted the traffic into another channel, only to be revived, however, on a much more extensive scale with the construction of the Suez Canal.

The tides are very variable, depending largely on the direction and force of the winds, which also to a great extent determine the direction and velocity of the surface currents. The hot climate is due to the almost cloudless sky, and consequent want of rain, the altitude of the sun, and the absence of rivers. The mean temperature of the air generally ranges between 70° and 94° F. during the day, though readings of over 100° are often registered in the shade; but during the night the temperature may fall to the freezing-point, owing to radiation in the clear atmosphere. The prevailing wind on shore is north-north-west almost universally, but from October to May south-south-east

winds prevail over the southern portions of the sea, a belt of calms and variable winds occurring in the central regions, while in the northern portions the usual north-north-west winds are met with. Evaporation is very great, and the air over the water is always very moist in the summer; hurricanes are unusual, but rain-squalls frequently occur with the southerly winds, and moderate gales and sandstorms, called 'dragons' in the popular language of the Arabs, are not uncommon.

The mean temperature of the surface water in the Red Sea varies at the northern end between about 65° and 79° F. in the central regions between 75° and 86° , and at the southern end between 78° and 89° ; readings of over 100° have been recorded at the south end of the sea. The temperature of the water below the surface decreases down to a depth of about 200 fathoms, from whence down to the bottom a mean temperature of about 71° is found all the year round; this agrees with the temperature conditions prevailing in the enclosed seas of the East Indies, for instance, according to the observations made on board the *Challenger*, the depth at which the minimum temperature occurs (i.e. 200 fathoms in the Red Sea) indicating the depth of water over the barrier separating the Sea from the open ocean. In winter, in the northern part, the whole body of water from surface to bottom usually has a mean temperature of 71° .

The salinity of the water is almost constant at about 1.030 (ordinary ocean water is about 1.026), and this is due to the fact that no rivers flow into it, little rain falls, and the evaporation is excessive. It has been estimated that, were the Red Sea entirely enclosed, it would become a solid mass of salt in less than two thousand years, but this is prevented by an inflow of water through the Strait of Bab-el-Mandeb, and it is also known that a current of very salt water flows out underneath the incoming surface current.

The greatest depth in the Red Sea is about 1200 fathoms, and the mean depth of the whole area about 375 fathoms. From the point of greatest depth, which is near the centre, the bottom rises towards each end. Owing to the absence of rivers the deposits approach in character those formed in the open ocean, being largely composed of Foraminifera, Pteropods, and other pelagic shells. The marine fauna and flora are extensive; a migration of the Red Sea and Mediterranean fauna is taking place along the Suez Canal. The origin of the name—the lat. *Mare Rubrum* and the Gr. *Erythra Thalassa*—is much disputed.

Redshank. See SANDPIPER.

Redstart (*Ruticilla phoeniceus*), a bird of the family Sylviidae, ranging in Europe from the North Cape to the wooded regions of central and southern Europe; in Asia to the valley of the Yenesei in summer, and to Palestine, Arabia, and Persia in winter; in Africa from the Canaries and Madeira and Senegal to Abyssinia in winter. In Great Britain it is a summer visitor to most parts, though unaccountably absent from some; in Ireland it has been very seldom recorded, but since the summer of 1885 it has nested annually at Power's Court, Conny Wicklow. The male is about $5\frac{1}{2}$ inches long, has the head, back, and wing-coverts slaty-gray; the forehead and eye-streak white; chin, throat, and cheeks jet black; wings brown, with pale outer edges; the tail and upper tail-coverts bright rufous chestnut; the rest of the under parts buff; bill black; legs and feet brown. The female has the upper parts grayish brown, under parts lighter, the tail less brilliant, and no bright colours on the head. The redstart is a bird of lively manners. Its food consists of flies, gnats, small butterflies, and other insects; the young are fed

largely on caterpillars. The nest is built of moss and dry grass, lined with hair and feathers, in holes in trees or walls; the eggs are usually six in number, and of a light blue colour. The song is slight, but soft and melodious; the alarm note is a plaintive *cheet*. In some parts of the country this bird is called the 'Fire-tail,' *start* being derived from the Old English *steort*, 'tail.' The Black

Redstart (*Ruticilla phoeniceus*).

Redstart (*R. titys*) is now a well-known visitor to many parts of the English coasts, especially of Devon and Cornwall, in autumn and winter, and also to the east and south coasts of Ireland. It is more rare in Scotland, but it has been found as far north as the Pentland Skerries. It has been recorded in Iceland, the Faeroes, southern Scandinavia, and Denmark. From Holland southwards it is abundant in spring. Its home is in southern Europe and Northern Africa, whence it ranges eastwards to the Ural Mountains, Palestine, and Nubia. Other species of redstart are found, one (*R. mesoleuca*) in Cyprus, Asia Minor, and Persia; another (the Indian Redstart, *R. ruficentris*) from Lebanon eastward; and a third (*R. ochrurus*) in the Caucasus and Armenia.

Red Water. See BLACK WATER.

Red Water (*Piroplasmosis*), a cattle disease known on the Continent as Hemoglobinemia or Hemoglobinuria, in the United States as Texas Fever, in South America as Tristeza or Bovine Malaria, in Australia as Tick Fever. It was first scientifically studied in the United States by Smith and Kilborne from 1889 to 1892. They found it was due to a somewhat pear-shaped parasite found in the red blood corpuscles, generally in pairs, hence they called it the *Piroplasma bigeminum*. It is not a contagious disease in the ordinary sense of the word, but is only communicated from animal to animal by the bites of ticks. It is much more fatal to adult cattle than to young animals; and in countries, or even districts, where it is indigenous and prevalent, the calves grow up practically immune to it. But there is great risk in introducing cattle from a country where it is not known to a Red Water country or district. Hence the danger of sending cattle from Britain to South Africa, even as far north as Rhodesia. Animals can be rendered almost immune by inoculation.

Redwing (*Turdus iliacus*), a species of Thrush (q.v.), well known in Britain as a winter bird of passage. It spends the summer in the northern parts of Europe and Asia; it occurs in Iceland, and straggles even to Greenland: its winter range extends to the Mediterranean, Persia, Northern India, and Siberia as far as Lake Baikal. In size it is somewhat smaller than the song-thrush or

mavis. Its flight is remarkably rapid. The general colour is a rich clove-brown on the head, upper parts of the body, and tail; the wing-feathers darker, but with lighter external edges; the lower parts mostly whitish, tinged and streaked with

Redwing (*Turdus iliacus*).

brown; the under wing-coverts and axillary feathers bright reddish orange. The redwing arrives in Britain rather earlier than the Fieldfare (q.v.), and, like it, congregates in large flocks, but is less numerous and less gregarious. Its food consists of insects, small snails, and berries. It has an exquisite, clear, flute-like song, which it pours forth from the summit of a high tree, gladdening the woods of the north.

Redwood. See PINE, SANDALWOOD. The Redwood of Australia is *Eucalyptus transcontinentalis*, one of the chief tannin-bearing species, common in the Western Australian goldfields.

Ree, LOUGH, a lake in the centre of Ireland, between Connaught and Leinster, is an expansion of the river Shannon (q.v.)

Reed, the common English name of certain tall grasses, growing in moist or marshy places, and having a very hard or almost woody culm. The Common Reed (*Phragmites communis*, formerly *Arundo Phragmites*) is abundant in Britain and continental Europe, in wet meadows and stagnant waters, and by the banks of rivers and ditches. It grows chiefly in rich alluvial soils. The culms are 5 to 10 feet high (the variety *P. c. pseudodumax* reaches 33 feet near Luckau in Prussia), and bear at the top a large, much-branched panicle, of a reddish-brown or yellowish colour, having a shining appearance, from numerous long silky hairs which spring from the base of the spikelets. The two outer glumes are very unequal; and the spikelet contains 3 to 4 perfect florets, with a barren one at the base. The culms are used for making garden-screens, for light fences, for thatching, for making a frame-work to be covered with clay in partitions and floors, &c. So useful are reeds in these ways, and particularly for thatching, that it is found profitable in some places to plant them in old clay-pits. Probably they might be planted with advantage in many peat-mosses where they are now unknown. The plant is not very common in Scotland; but in the fenny districts of the east of England it covers large tracts called *reed-ronds*, and similar tracts occur in many parts of Europe. Nearly allied to this is *Arundo Donax*, plentiful in the south of Europe. It is 6 to 12 feet high, and has very thick, hollow, woody culms, and a purplish-yellow panicle, silvery and shining from silky hairs. The woody stems are an article of commerce, and are used for reeds of clarionets, mouth-pieces of oboes, &c., walking-sticks and fishing-rods. (See also WRITING.) The creeping roots contain much farina and some sugar. Of

Arundo Karika (called *Sur* in Sind) the flower-stalks are very fibrous; and the fibres, being partially separated by beating, are twisted into twine and ropes. The Sea Reed is *Ammophila*—or *Psammodi*—*arundinacea*.

Reed, in Music, the sounding part of several instruments, such as the clarinet, bassoon, oboe, saxophone, and bagpipe, so called from its being made from the outer layer of a reed (*Arundo Donax*) found in the south of Europe. The name is also applied to the speaking part of the organ, though made of metal. Reeds are generally divided into two kinds—the *beating* reed, used in the organ, clarinet, &c., requiring to be placed within a tube to produce a musical sound, and the *free* reed, used in instruments of the harmonium and concertina kind. The Organ (q.v.) reed (fig. 1) consists of a metal tube, *a*, with the front part cut away and having a metal (brass, German-silver, or steel) tongue, *b*, covering the orifice, attached at the upper end, and bent forward at the lower end to permit of vibration. The admission of a current of air to the outer tube causes the tongue to vibrate against the edge of the opening in the tube *a*, producing a musical note, the pitch of which is determined by the length of the free end of the reed;

Fig. 1.

Fig. 2.

this is regulated by a strong movable spring, *c*, pressing against it, the quality of the sound depending on the length and form of the outer tube. In the Clarinet (q.v.) reed the mouth forms the outer tube. The reed in the drone of the bagpipe is on the same principle as the organ reed, and is made of a piece of reed tube a few inches long, cut across a knot at one end so as to make a stop. A slit is cut in it with a knife to make the tongue. It is shown in fig. 2, *a*, *in situ*, the outer tube being shown in section, the air enters from the bag in the direction of the arrow; the free end is the stopped one. The double beating reed (fig. 2, *b*) is that used in the bassoon, oboe, and the chanter of the bagpipe, and consists of two reeds, shaped so as to be tied together in the form of a tube at one end, either with

Fig. 3.

or without the aid of a metal pipe, to fit the end of the instrument, and thinned away at the other

end, where the two meet with a little space between them in the centre. The air being blown into the thin end causes the two reeds to vibrate against one another. The free reed, shown in fig. 3, consists of a metal tongue, *b* and *c*, fixed at one end to a metal plate, *a*, having an elongated slot large enough to allow the free end of the tongue to vibrate through it on the admission of a current of air; and this vibration forms the note, the pitch of which is regulated by the length of the reed.

Reed Bird, Reed Mace, Reed Warbler. See BOB-O-LINK, BULRUSH, WARBLER.

Reel, a lively dance, popular in Scotland, which may be danced by two couples, but admits a greater number. The music is in general written in common time of four crotchets in a measure, but sometimes in jig time of six quavers.

Rees, ABRAHAM (1743–1825), a native of Montgomeryshire, and Unitarian minister for forty years at the Old Jewry, London, re-edited the Encyclopædia (q.v.) of Ephraim Chambers (1778, 1781), and compiled one of his own (1802–1820).

Reeve (O.E. *gerfa*), an old English magistrate; thus there were *borough-reeves*, *port-reeves*, &c. The Sheriff (q.v.) is the *shire-reeve*. The reeve in Chaucer is the Scottish *griec* or land-steward.

Reeve, CLARA, novelist, daughter of the rector of Freston in Suffolk, was born at Ipswich in 1729, lived a quiet life, and died unmarried, 3d December 1807. She translated Barclay's *Argenis* (1772), and in 1777 published the *Champion of Virtue*, a Gothic Story, renamed next year *The Old English Baron*, avowedly an imitation of Walpole's *Castle of Otranto*. She produced four other novels, and *The Progress of Romance* (1785).

Reeve, HENRY, C.B. (1813–95), was born at Norwich, and educated there and on the Continent, where he formed many acquaintances with French men of letters. He was registrar to the Privy Council (1843–87), and editor of the *Edinburgh Review* (from 1855), and edited the *Greville Memoirs* (1875, 1885, 1887).

Reeves, JOHN SIMS (1818–1900), born at Shooter's Hill, Kent, appeared in public as a baritone at Newcastle in 1839, and acquired fresh fame, but as a tenor, in London. He studied at Paris (1843), sang at Milan, and was recognised as the first English tenor. Leaving the operatic stage (after 1860) he became popular as a ballad-singer at concerts and in oratorio. See his own *My Jubilee* (1889), and the Lives by Sutherland Edwards and Pearce.

Referendum. See INITIATIVE AND REFERENDUM.

Reflection. A surface on which a beam of light falls may be either rough or smooth. If it be rough, the greater part of the incident light is irregularly scattered by the innumerable surface facets, so as to be reflected or dispersed in all directions; if it be smooth, a proportion (but never the whole) of the incident light is regularly reflected or turned back in definite paths. A smooth, dustless mirror is not visible to an eye outside the track of rays reflected from it. If the polished surface be that of a transparent substance (e.g. glass) optically denser than the medium conveying the light to it, comparatively little light is reflected; but the more oblique the incidence, the smoother the polish, and the greater the difference between the optical density of the glass and that of the medium in which it is immersed, the greater the proportion reflected. Thus less light is reflected from glass

under water than from glass in air; and conversely, if the light travel in the denser medium and strike the bounding surface between it and a rarer medium—as where light ascending through water strikes its upper free surface—it will, if its obliquity of incidence exceed a certain limit, be almost totally reflected: the small loss that ensues arising wholly from absorption, while no light is transmitted into the air above. This may be shown by holding a clear tumbler of water above the head: the image of objects beneath is seen reflected in a bright mirror surface; and a phenomenon of the same order is seen on thrusting a test-tube containing air below the surface of water, when it will appear to have a lustre like quicksilver. If the reflecting surface be that of an opaque body the bulk of the incident light is reflected, a percentage being lost by absorption. What has been said about light applies equally to ether-vibrations of all kinds, and therefore the theory of reflection has general reference to radiant heat, light, actinic radiation, and electro-magnetic undulations (see MAGNETISM). Reflection arises in all cases from a difference in the transmissibility of ether-disturbances on the two sides of the bounding surface.

On reflection from polished surfaces we have, so far as regards the directions of the reflected rays, the following laws observed: (1) The incident 'ray,' the normal (i.e. a line drawn perpendicular to the surface at the point of incidence, and the reflected 'ray' all lie in one plane, the 'plane of incidence;' and (2) the angle of incidence (the angle which the incident 'ray' makes with the normal to the reflecting surface) is equal to the angle of reflection (the corresponding angle between the normal and the reflected 'ray'). These laws apply equally to ether-waves of all lengths, and therefore to light of all colours; and they also hold good whatever be the shape of the surface. If the surface be plane their application is simple; and if the surface be curved we have, in effect, to consider the curved surface as made up of indefinitely small facets, to each of which the above laws can be applied. The geometrical consequences of these laws make up what used to be called *Catoptrics*, that part of geometrical optics which deals with reflection; and this coincides in its propositions with that part of kinematics which gives an account of the reflection of waves. Here the ether-waves (using the term 'waves' in its most general sense) are assumed to travel through optically homogeneous media, and can consequently be traced out by imaginary lines drawn at right angles to the wave fronts or along the directions pursued by the waves, these imaginary lines being called 'rays.'

Plane Reflecting Surfaces.—(1) Rays which are parallel to one another before striking a plane reflecting surface are parallel after reflection. (2) If light diverging from or converging towards a point, Q , be reflected from a plane mirror, it will appear after reflection to diverge from or converge towards a point, q , situated on the opposite side of the mirror and at an equal distance from it. In fig. 1, the rays diverge from Q ; after reflection they appear to diverge from q . If,

Fig. 1.

on the other hand, the course of the light is such that the rays appear before reflection to converge upon q , they will after reflection actually pass through Q . (3) A consequence of the preceding proposition is that when an object is placed before

a plane mirror the virtual image is of the same form and magnitude as the object, and at an equal

Fig. 2.

distance from the mirror on the other side of it. The right hand of the image, taken as looking towards the mirror, is necessarily opposite to the left hand of the object; so that no one ever sees himself in a single plane mirror as others see him or as a photograph shows him, but he sees all his features reversed. (4) When two mirrors are placed parallel to one another, light from an object between them is reflected back and fore, so as to appear on each occasion of reflection as if it came from images more and more remote from the mirrors. On each occasion the course of the rays of light is the same as if the virtual image behind the mirror had been a real object; and a new virtual image is produced, apparently as far behind the reflecting mirror as the virtual object had been in front of it. Thus, in fig. 3, where AB and CD are mirrors, the distance $Q \cdot CD = CD \cdot q_1$; $q_1 \cdot AB = AB \cdot q_2$; and so on indefinitely; and also $Q \cdot AB = AB \cdot q'$; $q' \cdot CD = CD \cdot q'$; and so on indefinitely; so that if the mirrors were perfectly plane and parallel, and if they reflected all the light

Fig. 3.

which fell on them, an observer between the mirrors would see in this experiment (which is called the *endless gallery*) an indefinite number of images. A variation of this experiment, carried out with mirrors not parallel to one another, but inclined at an angle which is some aliquot part of 360° , gives the principle of the *Kalidoscope* (q.v.).

(5) When a beam of light is reflected from a mirror and the mirror is turned through a given angle the reflected beam is swept through an angle twice as great. This principle is utilised in the construction of many scientific instruments, in which the reflected beam of light serves as a weightless pointer, and enables us to measure the deflection of the object which carries the mirror. (6) When a beam of light is reflected at each of two mirrors inclined at a given angle the ultimate deviation of the beam is (if the whole path of the light be within one plane) equal to twice the angle between the mirrors; for example, in fig. 4, the angle SDB , which measures the ultimate deviation of the original beam SA , is easily proved equal to twice the angle BCA between the two mirrors. This proposition is applied in the *Quadrant* (q.v.) and *Sextant* (q.v.). (7) When a wave of any form is reflected at a plane surface it retains after reflection the form which it would

Fig. 4.

have assumed but for the reflection, this form being, however, guided by reflection into a different direction.

Curved Reflecting Surfaces.—In these we have to trace out the mode of reflection of incident rays from each 'element' or little bit of the reflecting surface; and this leads, through geometrical working, to such propositions as the following: (1) Parallel rays, SP , travelling parallel to the axis of a concave paraboloid mirror (fig. 5) are made to converge so as all actually to pass accurately through F , the geometrical focus of the paraboloid; and, conversely, if the source of light be at F , the rays reflected from the mirror emerge parallel to one another—a proposition of great utility in lighthouse work, search-lights, &c. (2) If the paraboloid mirror be convex, parallel incident rays have, after reflection, the same course as if they had come from the geometrical focus of the paraboloid. (3) In a concave ellipsoid mirror, light diverging from one 'focus' of the ellipsoid is reflected so as to converge upon the other 'focus' of the curved surface; and by a convex ellipsoidal mirror light converging towards the one focus is made to diverge as if it had come directly from the other focus. (4) In a hyperboloid reflector the two geometrical foci have properties corresponding to those of the ellipsoid. (5) In spherical reflectors, which are those most easily made, there is no accurate focus except for rays proceeding from the centre and returning to it. When parallel rays are incident on a concave spherical mirror we see from fig. 6 that if they be parallel to the axis of the mirror each ray is made to pass after reflection through a point, q , which is nearer to F (a point midway between the mirror and its centre, O) the narrower is the pencil of rays. If, therefore, the pencil of rays be very narrow in comparison with the radius, OA , the rays will after reflection approximately converge upon F , which is called the principal focus of the mirror; and the principal focal distance, $AF = \frac{1}{2}AO = \frac{1}{2}r$, where r is the radius of the spherical mirror. The farther any ray is from the axis AO , the farther from F is the point, q , to which that ray is reflected; and the difference, Fq , is called the longitudinal aberration for that ray. The reflected rays from the various parts of the mirror form by their intersection a Caustic (*q.v.*), the apex or cusp of which is at F . If,

Fig. 5.

Fig. 6.

Fig. 7.

instead of using a parallel beam of incident light, we have light coming from a point at a definite distance along the axis, we find (see fig. 7) first that any ray from Q to A travels back along AO , whence the focus of reflection is somewhere in the line AOQ ; and that any ray, QP , is reflected to a point, q , such that the angle $QPO = qPO$; and

therefore (since by Euclid, vi. 3, $QO : qO :: QP : qP$) if the pencil be relatively very narrow, so that QP comes to be equal to QA , and qP to qA , we have $QO : qO :: QA : qA$. This proportion reduces to the equation $1/Aq + 1/AQ = 2/AO$; whence we can readily find Aq when AQ and AO are known. Thus, if, for example, the radius of curvature AO be 12 inches (the principal focal length being then 6 inches), and if Q be 30 inches from A , we have $1/Aq + 1/30 = 2/12$; whence $1/Aq = 8/60$ and $Aq = 7\frac{1}{2}$ inches. The same formula may be written $1/d + 1/d' = 1/f$, where d and d' are the distances from A of the two 'conjugate' foci, q and Q , and f is the principal focal length. The two 'conjugate' foci are reciprocal; if light start from q it will be reflected to Q . As Q , the source of light, approaches O , q also approaches O ; when Q is at O , q also is at O ; as Q continues to move towards F , q moves out more and more rapidly beyond O ; when Q is at F , q is at an infinite distance, or

Fig. 8.

the reflected rays are parallel; when Q is between F and A the reflected rays are divergent, as if from a virtual focus on the opposite side of A . If the mirror be convex, fig. 8 shows that AO and AQ have, with respect to the reflecting surface, opposite signs; so also have AO and AQ ; so the equation

above becomes $1/Aq + 1/AQ = -1/AO$; whence, taking the same numbers as before, Aq is equal to -5 inches; a virtual image, seeming to come from a point 5 inches on the other side of the reflecting surface.

In the foregoing it has been assumed not only that light is propagated with equal velocities in all directions, but also that the mirror itself is at rest. The guiding principle is then Huyghens's Principle. Assume a plane wave-front to strike a plane mirror obliquely; the different elements of the plane wave-front impinge upon the plane mirror at successive instants of time. Consider the instant t at which the wave-front has come to encounter a more remote point of the mirror; at that point and that instant reflection is merely beginning; but at that same instant reflected light must have already travelled in space from an earlier reflection point as far as somewhere on the surface of a sphere whose centre is the earlier reflection point and whose radius depends on the interval of time involved in the expression 'earlier.' Consider an array of such earlier reflection points, each with its own time interval, and its own smaller or larger sphere; the aggregate result will be that the light will, at the instant t , have reached a reflected plane wave-front the direction of whose propagation (the 'reflected ray') follows the fundamental laws (1) and (2) above. If, however, the mirror be itself in motion, the centres of the respective spheres are progressively displaced in space and the geometry of the construction is distorted; we still have a reflected plane wave-front which follows law (1), and we still have an 'angle of reflection,' but law (2) is departed from and replaced by a much more complicated expression.

As to the quality of the light reflected there are some peculiarities to be observed. From the surface of a transparent body, of greater optical density than the surrounding medium, light polarised in the plane of incidence and reflection is more largely reflected at oblique incidences than light polarised at right angles to that plane; when the angle of incidence is such that the

reflected and refracted rays tend to be at right angles to one another, the whole of the light reflected is polarised in the plane of incidence and reflection; and if light polarised at right angles to that plane be made to fall upon glass at the particular angle of incidence just referred to, it will not be reflected at all, but will wholly enter the glass. Plane-polarised light polarised in any other plane than that of incidence or one at right angles to it, is, after total reflection in glass, found to be elliptically polarised (see POLARISATION); and this phenomenon is always presented in reflection from metals. In the case of electro-magnetic radiation (see MAGNETISM) theory and practice concur in indicating that conductors are good while non-conductors are bad reflectors; and the same general proposition holds good with reference to those more frequent but otherwise similar ether-oscillations to which the phenomena of Radiant Heat, Light, and Actinism are due.

Reflex Action. See NERVOUS SYSTEM.

Reform is a comprehensive name for those changes in the law by which the House of Commons has been made a more truly representative body. In the 18th century only freeholders voted in English county elections; in many boroughs the franchise was restricted to members of the corporation; boroughs of this class were usually under the influence of the crown or of some wealthy individual who regarded them as a part of his property. In 1745 Sir P. Dashwood moved an amendment to the address, claiming for the people the right to be freely and fairly represented; in 1766 Lord Chatham took up the cause of Reform; Wilkes proposed an excellent scheme of redistribution in 1776; in 1780 the Duke of Richmond proposed annual parliaments, universal suffrage, and equal electoral districts; but his plan met with no support. Pitt entered public life as an avowed reformer, and in 1785 he introduced a measure of redistribution; the part of his scheme most open to objection was the proposal to compensate owners of rotten boroughs. His bill was rejected, and he dropped the subject. The king was opposed to change, and in the public mind reform came to be identified with the revolutionary opinions which were beginning to prevail in France. Fox kept alive the demand for a wider franchise and a better distribution of power. Lord J. Russell's first motion on the subject was proposed in 1820, and in 1830 he accepted office under Lord Grey. A Reform Bill was brought in, and the second reading was carried by a majority of one. A subsequent defeat in committee compelled the government to dissolve. The country declared unanimously for Lord Grey; his second Reform Bill was passed in the Commons by a large majority. It was rejected by the Lords, and the same fate would have befallen a third bill introduced in 1832, but the resistance of the Lords was overcome by the threat to create as many new peers as might be necessary to pass the bill. After something like a century of discussion the first Reform Act received the royal assent. The greater part of the labouring classes were still unfranchised; but the Radical reformers were still unsatisfied; but the Whigs and Tories were unwilling to disturb the settlement of 1832. Agitation was stimulated by the so-called People's Charter put forth in 1838; but it was not till 1852 that Lord J. Russell reopened the question of Reform. Successive governments continued to bring in abortive schemes, until at last in 1867 Lord Derby and Disraeli succeeded in passing the act by which household and lodger franchises were extended to the boroughs. In 1884 Gladstone proposed to assimilate the franchise in counties to that which had been given to the boroughs; but the Lords refused to pass any bill for extending the

franchise until the details of the government scheme of redistribution were before them. The bill was reintroduced in autumn, and the question at issue between the two Houses was settled by a compromise. The government agreed not only to communicate their plan of redistribution to the leaders of the opposition, but to settle the details by mutual arrangement; Lord Salisbury and Sir S. Northcote attended meetings of the cabinet, and conferred with ministers. The results were embodied in bills which were passed into law before the general election of 1885. The Representation of the People Act (1918), besides redistributing seats on the basis of one member for every 70,000 of the population (43,000 in Ireland by another act), enfranchised all men of twenty-one years not specially incapacitated, who were qualified by residence or by occupation of business premises of £10 yearly value; and all women of thirty years who were, or whose husbands were, so qualified. The lodger franchise (for furnished rooms) was abolished.

At the end of the reign of George III. there were, in a population of 22,000,000, only 440,000 voters. The Reform Bill of 1832 added less than 500,000; the reform of 1867-68 increased the electorate from 1,136,000 to 2,448,000. At the passing of the measures of 1884-85 the electorate had by natural growth risen to about 3,000,000; the Act of 1884 added 2,000,000 voters. In 1918 the number was raised from about 8,350,000 to 21,270,000.

See PARLIAMENT, REPRESENTATION, CHARTISM, GLADSTONE, GREY (EARL), RUSSELL; May's *Constitutional History*; Butler's *Passing of the Great Reform Bill* (1914); and the speeches of Gladstone, Bright, Disraeli, &c.

Reformation. The religious revolution of the 16th century, known as the Reformation, is the greatest event in the history of civilisation since Paganism gave place to Christianity as the faith of the leading nations of the world. It marks the supreme importance of this revolution that the age which preceded and the age which followed it belong to two different phases of the human spirit. With the Reformation begins what is distinctively known as *Modern Europe*, while the epoch that preceded it bears the equally distinctive designation of the *Middle Ages*. As a revolution in which all the countries of western Europe were more or less directly involved, the subject of the Reformation has necessarily been treated in the different accounts of these countries. In the articles on Luther, Charles V., Henry VIII., Calvin, Knox, and others further details will be found regarding the aims and methods of the revolution in the various countries where it declared itself. Here, therefore, it will be sufficient to indicate briefly the general causes which produced it, the special course and character it took among the different peoples, and its chief results for the human spirit at large.

The central fact of the Reformation was the detachment from papal Christianity of the nations distinguished by the general name of Protestant. By this severance an order of things came to an end under which Christian Europe had been content to exist from the close of the 8th century. From the year 800, when, by a mutual understanding of their respective functions, Charlemagne was crowned emperor of the Romans by Pope Leo III., western Europe had come to regard the papacy as the essential condition of individual and corporate life, as prime a necessity in human affairs as the sun in the course of nature. Thus conceived, the power of the church underlay all human relations. It was the consecration of the church that constituted the family; the church defined the relations of rulers and their subjects, and the church was the final court of appeal on the ultimate questions of human life and destiny.

In the nature of things such a power could never be realised as it was ideally conceived. Yet during the 11th and 12th centuries, the period when the power of the popes was most adequate to their claims, they undoubtedly went far to make the idea a reality. But the energies of the human spirit were bound sooner or later to issue in developments with which medieval conceptions were fundamentally irreconcilable. By the 13th century, along every line of man's activity, there were already protests, conscious and unconscious, against the system typified in the pope at Rome.

The most remarkable of these protests was the order of ideas associated with the name of Joachim of Flora in Calabria (died 1202). Under the name of the 'Eternal Gospel' (used for the first time in 1254) these ideas ran a course which for a time seriously threatened the existence of the mediæval church. The new teaching struck at the very root of the papal system, for its essence was that the hour had come when a new dispensation, that of the Holy Spirit, should supersede the provisional gospel delivered by Christ. During the second half of the 13th and the first half of the 14th century the influence of these ideas is traceable in every country of Christendom, and it was only the unflinching action of the church that postponed its disintegration for other three centuries. The numerous sects which either sprang from or were quickened by this movement speak clearly of the revolutionary fever that had seized on men's spirits and was impelling them to other ideals than the traditions of Rome. Mainly the offspring of the third order of St Francis, these sects swarmed throughout every Christian country under the names of Beguins, Beghards, Fratricelli, Flagellants, Lollards, Apostolic Brethren, &c., and everywhere spread discontent with the existing church. Even John Knox (in answer to a letter by James Tyrie, a Scottish Jesuit) claims Joachim of Flora as an ally in the work which it was the labour of his own life to achieve—the ruin of the papacy, and the promotion of what he deemed a purer gospel.

Simultaneously with this manifestation of revolutionary feeling there were tendencies in the sphere of pure thought in essential antagonism to the teaching of the church. The labour of the thinkers of the middle ages was to reconcile faith, as inculcated by religious authority, with human reason as they found it embodied in the accessible writings of Aristotle. In the 13th century, however, the Arabic texts of Aristotle, and notably that of the great commentator Averroës, made their way into the Christian schools, and thenceforward a leaven of scepticism was a present element in all the universities of Europe. As the result of the teaching of Averroës, a name of the most sinister import to every true son of the church, materialism and pantheism became common creeds among thinkers, and the notion spread even among intelligent laymen that Christianity was not the absolute thing the church had taught them to believe. In Dante's (died 1321) fierce exclamation that the knife is the one reply to him who denies the immortality of the soul we have the outburst of a passionate faith in presence of a widespread libertinism of thought.

But the most serious menace against the integrity of the papal system lay in the political development of Europe during the last three centuries of the middle ages. As the countries of western Europe became more and more individualised, their peoples grew every year into a fuller consciousness of distinct national interests and national ideals. While this was the tendency of the various nations, the pope during these centuries gradually lost his position as the disinterested empire of Europe, and sank into an Italian prince, with a temporal

policy of his own which led him to seek allies among other potentates as they fell in with his own special ends of the moment. But such alliances naturally gave offence to the princes excluded from them, and led to a suspicious discontent with the Roman see, which, as was afterwards proved in the case of England, needed only the requisite occasion to flame into outright rebellion. The saying of Philip Augustus (died 1223) 'Happy Saladin, who has no pope!'—expressed the feeling, which every century grew stronger, that the pope would become an impossible factor in European politics. To this feeling should be added the fact that, as the middle classes grew in intelligence and well-being, they looked with envy on the immense wealth of the clergy, and grumbled at the large sums that annually went to the coffers of Rome.

During the 14th and 15th centuries mediævalism gave every sign of an exhausted phase of human development. By the so-called Babylonish Captivity, when the papal residence was fixed for seventy years at Avignon (1305-76), and by the Great Schism (1378-1417), during which the spectacle was seen of first two and afterwards three popes claiming to be the vicar of God on earth, the papacy suffered a loss of prestige in the eyes of all Europe which it never afterwards fully recovered. It was the further misfortune of the church during this eclipse of its ancient glory that all spiritual life seemed to have gone out of every rank of its clergy. Testimonies from every country prove beyond question that by the end of the 15th century the clergy had become grossly unfit to be the spiritual guides of the people. The sources of intellectual life had equally tailed wherever the old philosophy authorised by the church continued to be the subject of teaching and study. In the later half of the 15th century scholasticism had become the veriest trifling which ever engaged the mind of man. In all the interests of man's well-being, therefore, a renaissance was needed to evoke new motives and supply new ideals which should lift humanity to a higher plane of endeavour. Such a renaissance came, and fortunately the church did not prove equal to suppressing this second burst of life as it had suppressed that of the 12th and 13th centuries.

It was again in Italy that the new life first declared itself. While north of the Alps scholasticism reigned in all the schools, the movement known as the Renaissance (q.v.) had in Italy been in full course for above a century. In itself the Renaissance was as far as possible from leading men to higher ideals in religion; yet in two of its results it gave a direct impetus to the Reformation. Inspired by the life of antiquity, the humanism of the Renaissance paganised the church and quickened that moral disintegration which was the prime cause of the religious revolution. On the other hand, through its opening of men's minds by new studies and new measures of things, the Renaissance lightened the load of tradition, and made a new departure in the life of Christendom a less formidable conception. In Erasmus (1467-1536), who has always been regarded as a true nursing father of the Reformation, we clearly discern these two results of the revival of the ancient literatures. In so many words he states his grave fears lest the church should be wholly paganised by the universal imitation of classical modes of thought and speech; while his own unsparring criticism of the church and its traditions proves how much he owed to the so-called 'new learning.'

The very zeal with which the revival of antiquity was pursued in Italy was itself a countercheck to religious reform in the country that of all others needed it the most. All contemporary literature

proves that during the later part of the 15th and the opening of the 16th century the court of Rome was as profoundly immoral as that of any of the heathen emperors had been in the same city. The spiritual claims of the papacy were the jest of ecclesiastics themselves. 'This fable of Christ,' a certain dignitary of the church is reported to have said in the Vatican, 'has been to us a source of great gain.' Among the Italian people, however, there was never the slightest indication of a national movement towards any serious breach with the papacy. The religious melodrama enacted by Savonarola at Florence (1489-98) never struck at the central ideas of papal Christianity; and Savonarola, besides, never like Luther or Knox woke a deep response in the national consciousness. While in Italy, therefore, there was no widespread religious quickening as in other countries of Christendom, there was no political reason such as elsewhere produced a breach with the papacy. For the Italian people the pope was not a foreign prince with temporal interests of his own conflicting with those of the nation at large. The different republics which partitioned the country might at times regard the pope as an enemy to their individual ambitions; but the nation as a whole was fully conscious of the honour of having the vicar of God in their midst, and as in the past they had stood by him against the emperors, so in the great religious revolution of the 16th century they also remained faithful to him throughout the gradual dismemberment of his spiritual dominion.

Of the countries north of the Alps Germany was the first to be widely influenced by that revival of learning which had its origin in Italy. In Germany, however, the new spirit wrought under fundamentally different conditions, and lighted the way to vastly different issues. There was every reason why Germany should lead the way in the schism from Rome. Outside Italy Germany was the country where every abuse of the mediæval church was seen in its grossest form. The ignorance and sensuality of the clergy, the scandalous sale of livings, the disproportionate papal exactions—all these evils came to be vividly realised by the quickened consciousness of the nation. Between Rome and Germany, moreover, an antagonism existed in the very conditions from which mediævalism had sprung. It was in virtue of the mutual understanding between pope and emperor that the church came to fill the place it did in western Europe. But almost from the first the interests of Rome and the empire had been in collision, so that pope and emperor came to be mere rivals for the first place among the western powers. It was natural, therefore, that in Germany Rome should be regarded with a jealousy and suspicion which might easily grow into irreconcilable hostility.

These workings of the national mind found intensified expression in the acts and writings of Martin Luther, who, with a genius and audacity which have given him a place among the moulders of man's destinies, proclaimed the need of a new departure in the religious life of humanity. In rejecting the traditional claims of the papacy Luther at the same time supplied a new principle by which, as he contended, a higher and truer life of the soul might be lived. By his doctrine of Justification by Faith Luther threw each individual on his own responsibility for the reason and life which is entrusted to him. Hitherto the deepest concerns of men had been inextricably bound up with pope and priest, and in this had lain the essential principle of mediæval Christianity. By the new principle Luther made the pope no longer an indispensable factor in individual or corporate

life, and thus initiated a new phase in the development of society. As was to be expected, this principle, so organic in its working, cleft the German nation in twain, and gave rise to a struggle which did not close till more than a century after the death of Luther himself. Luther's attack on the sale of indulgences (1517), the burning of the papal bull (1520), Luther's condemnation by the Emperor Charles V. at the diet of Worms (1521), his temporary triumph at the first diet of Spire in 1526 (the beginning of modern Germany, according to Ranke), the confession of the Protestant faith at Augsburg (1530), are the outstanding events in the contest closed by the peace of Augsburg in 1555, nine years after Luther's own death, but again renewed in the disastrous Thirty Years' War (1618-48), and finally settled by the peace of Westphalia (1648).

The religious revolt of Germany left no country of Christendom unmoved. Before the 16th century had closed the bulk of the Teutonic peoples had followed her example and broken with the papacy. Under one aspect, indeed, the Reformation may almost be regarded as a Teutonic revolt against the domination of the Latin races. Between 1525 and 1560 Denmark and Sweden, taking the occasion of a political revolution, both declared for Protestantism; and in 1581 the United Provinces definitively threw off their double allegiance to Spain and the pope. But it is more important to trace the course of the revolution in the great powers of the West.

In Spain heresy of all kinds had no chance of finding a home. In its terrible inquisition, reorganised in 1478, it had an institution ready made for effectually dealing with all attempts at reform or revolution. Luther found followers in Spain as in other countries; but they were literally extinguished before their voices could be heard, and of all the great powers Spain profited least by the quickening spirit of the Reformation.

Much more interesting and important is the history of religious reform in France. Between 1520 and 1530, the period of Luther's greatest activity, both renaissance and reform found a firm footing in France, and so many circumstances seemed to favour the future of both that for a time it was doubtful with which side the victory would eventually lie. On the one side was the university of Paris, which throughout the middle ages had claimed for itself the right—denied to the pope himself—of sovereign decree on the truth or falsity of all religious doctrine. As its decrees had in every case the strenuous support of the parliament of Paris, the university was a formidable force to be reckoned with by every innovator in studies or religion. In 1519 Luther's dispute with Eck had been referred to the doctors of Paris for decision, and their judgment, delayed for two years, had been the unqualified censure of Luther's position. Thenceforward every advocate of the new religion, and they daily grew in numbers, especially among the middle class, both in Paris and in the provinces, was pursued by the unrelenting hate of the parliament and the university. On the other hand, the king (Francis I.), eagerly encouraged by his famous sister, Margaret of Navarre, who herself had strong Protestant leanings, was at first disposed to use the new religious movement as a weapon to his hand in his dealings with the court of Rome. In the end Francis saw that separation from Rome meant the disruption of the French nation, and after 1534 he resolutely set himself to the extermination of every heretic in his dominions. His son and successor, Henry II. (1547-59), carried out this policy with even greater rigour, but in spite of all efforts to suppress them the French Protestants grew into a body formidable alike by their position,

wealth, and intelligence. The Huguenot wars, the Massacre of St Bartholomew (1572), and the Edict of Nantes (1598) are the outstanding events in this long struggle, which, involving political as well as religious questions of the first importance, threatened the very existence of France by suggesting to Philip II. the possibility of annexing the divided country as a province of Spain. By the Edict of Nantes the French Protestants attained a certain measure of religious freedom; by its revocation in 1685 Protestantism was stamped out of the country, and France thus deprived of the noblest elements in its society.

The religious revolution in Switzerland is second only to that of Germany in its direct influence on the subsequent fortunes of the European nations. In Switzerland we have the case of a double revolt from Rome springing from the same conditions, yet each having a character and an animating soul of its own. At Zurich, as early as 1519, and independently of Luther, Ulrich Zwingli, who, according to Ranke, combined in himself the best elements of renaissance and reform, gave rise to a movement which split the Swiss cantons into two hostile sections, and issued in the peace of Cappel (1531), which permitted to each canton the choice of its own form of faith. More important than the movement of Zwingli at Zurich is that associated with Calvin and Geneva. As in almost every other case of revolt, political considerations wrought with religious zeal in the breach of Geneva with Rome. Before 1530 the town had received the new religion from French refugees, who thus gave its peculiar character to the creed eventually associated with Calvin and Geneva. But it was in the successful effort of the town in throwing off the yoke of the Catholic Dukes of Savoy (1534) that it found itself forced to join the great Protestant schism, and to fashion a civil and religious polity compatible with an independent corporate life. It was in the accomplishment of this task that Calvin proved himself the great consolidator of the tendencies that underlay the Protestant movement. Inspired by Calvin, it was the pre-eminent destiny of Geneva at once to produce a reasoned civil and religious creed and a type of Christian believer that offered a solid front against the vast powers still at the command of the Roman see, and assured to Protestantism its own independent course in the history of mankind.

In 1532 the schism of England from Rome also became an accomplished fact. In this result had issued the negotiations of Henry VIII. with Pope Clement VII. for his divorce from Catharine of Aragon. But the view summed up in Gray's line, 'And gospel light first dawned from Bullen's eyes,' implies a totally inadequate recognition of the many forces that went to produce the English Reformation. The king's divorce was the mere occasion of what must sooner or later have been the only solution of England's relations with the popedom. In England all the forces, in greater or less degree, were at work which had produced the religious revolution in Germany. As in Germany, the church alike in its teaching and practice no longer represented the highest consciousness of the nation. It has been shown that its degradation was far from being so general or so complete as the official reports of Henry had seemed to prove; yet the state to which it had come was clearly such as to lend some countenance to the most drastic measures against it. By the end of the 15th century, also, the Renaissance, which was everywhere the solvent of tradition, had found its representatives in England. Linacre, Grocyn, Colet, and Sir Thomas More were all men more or less emancipated from medievalism, though none of them broke communion with Rome. Both More

and Colet spoke their minds freely on the unworthy lives of the clergy; and the latter by his foundation of St Paul's School in 1510, and by his placing it under lay supervision, took a step of the highest importance in the direction of the new order. But it is in the political development of England that we find the adequate explanation of her final breach with Rome. For centuries the pope had come to be more and more regarded as a foreign prince, whose powers, as he claimed the right to exercise them over Englishmen and English property, were incompatible with English interests and English liberty. Moreover, by the date of Henry's accession the pope was a mere Italian prince, whose own interests led him to seek the support of the strongest arm. When Clement VII., therefore, declared against the divorce from Catharine, Henry regarded the decision not as the oracle of Christendom, but as the counsel of an earthly prince whose own interests left him no other alternative.

The breach with Rome was thus inevitable; but it still remained to be settled whether the old or the new religion should finally gain the English people. Henry himself to the close of his life professed to have broken with the old only in the one point of the headship of the church. In the reign of Edward VI. a clear departure was made from the doctrinal system of the ancient church; but the temporary reaction under Mary showed how strong a hold that system still possessed on the hearts of the people. When Elizabeth came to the throne in 1558 it was only her prudent policy that saved the country from the intestine divisions of France and Germany. Three parties were equally bent on realising their own conceptions of a religious settlement. The adherents of the old religion, who still probably made a half of the people, had not lost hope of a return to the old spiritual allegiance. Those who had renounced the papacy themselves made two distinct parties, each bent on ends so conflicting, that it was evident from the first that they could never work in common. The governing principle of the one party, from which eventually sprang the Church of England, was to minimise the differences between the old faith and the new, and as far as possible to maintain the continuity of the religious tradition in the country. The other, which drew its inspiration from Calvin and Geneva, and was afterwards known as the Puritan party, aimed at a root and branch rejection of papal Christianity as at once in the interest of what they thought a purer creed, and as the only safeguard against a return to the old constitution. It was owing to her politic handling of these conflicting parties that at Elizabeth's death England was of one mind regarding the question of the papal supremacy, and that the severance from Rome became a definitive fact in the development of the country. By happy turns of events, such as her excommunication by Pius V. in 1570, and by the extraordinary issue of the Spanish Armada in 1588, not only was the number of Catholics reduced, but such as still clung to the ancient faith thenceforward put their allegiance to their native prince before any claim of the Roman see. It was this final triumph of the Protestant revolution in England that saved the movement in all the other countries of Europe.

The triumph of the Protestant movement in Scotland is likewise a fact of the first importance in European history. In Scotland, from the very beginning of Luther's revolt, we find the presence of the same elements which elsewhere led to revolution. In Scotland as elsewhere the clergy had lost the respect of the country. As early as 1525 Lutheran books were so widely read that an act of parliament was passed forbidding

their importation. The very efforts of the church to stamp out the new heresy, as in the burning of Patrick Hamilton in 1528, and of George Wishart in 1546, served only to hasten the turn of affairs which it had dreaded. Jealousy of the wealth and political influence of the clergy disposed the nobility to throw in their lot with the party of revolution. When in 1559 Knox returned from his long sojourn abroad, his unflinching zeal and personal force supplied the momentum that was needed to complete a revolution already in full course; and in the following year Protestantism was formally established as the religion of the country. The consequences of this revolution extended far beyond Scotland. Had Mary on her return in 1561 found Scotland united in the Catholic faith, she would have commanded the destinies of England. Elizabeth could never have effected a religious settlement, and, with England paralysed, Protestantism could not have held its own against the united forces of Catholicism.

Christianity. At the beginning of the revolt the authorities of the ancient church did not fully realise that the forces arrayed against them menaced their very existence. When the true extent of the danger was realised the church displayed all the resources of an institution whose roots were in the very heart of Christendom, and which, alike by its traditions and by its special adaptations to the wants of the human spirit, appealed to the deepest instincts of a large section of all the peoples of western Europe. The Society of Jesus, founded in 1540, supplied an army of enthusiasts, whose policy and devotion saved Rome from dissolution. By the decrees of the Council of Trent (1545-63), inspired by the spirit and aims of the Jesuits, the church reaffirmed its traditional teaching, conceding nothing either to renaissance or reform; and a succession of popes during the latter half of the 16th century carried out with a zeal worthy of the better ages of the papacy the policy marked out for them by the Jesuits. Through the dismissal of the Protestants and the strenuous efforts of the papacy, the middle of the 16th century saw the tide of revolution checked; and in certain countries, more especially in Germany, the Jesuits even gained ground which had been lost. By the close of the same century Europe was partitioned between the two religious parties by the same dividing lines as exist at the present day.

It has been said that the central fact of the religious revolution of the 16th century was the severance of the Protestant nations from the Roman see; but the great schism inevitably led to issues of which the Protestant reformers never dreamed, and which they would have denounced in as unqualified terms as any theologian of the mediæval church. The reform of religion preached by Luther or Calvin implied no real change in the modes of thought that distinguished mediævalism. Their theology was but another form of scholasticism; their attitude to the classical tradition or to any departure from their own conception of the scheme of things was precisely that of the Schoolmen trained on the Decretals and Aristotle. For an infallible church they substituted the Bible as the unerring expression of God's relation to man; the interpretation of the Bible they left to the individual consciousness. This freedom was of necessity only nominal, since the members of any Protestant church were members only on condition of their accepting the church's interpretation of the contents

of the Bible, and since each different church deemed itself the special depository of the only true conception of the perfect will of God. Nevertheless, it was from this attitude of the Protestant reformers to the Bible that the developments of modern thought sprang. A reformer like John Knox would have stamped out every form of thought hostile to his own synthesis of things divine and human; but it was not in the power of the Protestant system to do what had been so effectually done by the church of the middle ages. In the mediæval conception church and state made one organism; what menaced the life of the one menaced the life of the other. Hence the state was at the church's bidding, whenever its arm was needed to deal with any suggestion of heresy. But having no great central head, such an organic union was impossible for any Protestant church, and religious error could not be regarded as a crime against the existing government. So complete was the revolution wrought by this changed relation of church and state that toleration of different creeds, and not an iron uniformity, was in time seen to be the indispensable condition of civil society. But in this lies the fundamental distinction between mediævalism and the modern spirit. Mediævalism rested on the belief that society was threatened if any of its members questioned the body of truth of which the church was the custodian; it is the distinctive principle of the modern spirit that truth shall be followed wherever facts are believed to lead.

For further information see the articles in this work on the chief reformers, especially Luther, Melancthon, Calvin, Zwingli, Cranmer, and Knox, and the works named there; also the articles on Renaissance, England (Church of), Scotland (Church History), Roman Catholic Church, Pope, Charles V., Henry VIII., Elizabeth. Here we can only enumerate certain important books along the lines of the foregoing article, and dealing more or less fully with the subject or part of it. Bryce, *The Holy Roman Empire*; Renan, *Joachim de Flor et l'Évangile Éternel*, and *Averroës et l'Arroisme*; J. A. Symonds, *The Renaissance in Italy*; Bishop Creighton, *A History of the Papacy during the Period of the Reformation*; Ranke, *Deutsche Geschichte im Zeitalter der Reformation*; Harnack's *History of Dogma* (vol. vi. transl.); Armstrong's *Charles V.*, the standard church histories from Gieseler to Meoiler (of the latter especially vol. iii.); Von Bezold and Veldner on the German Reformation; for the Roman Catholic point of view Dollinger's work on the Reformation, Pastor's *History of the Popes*, and Janssen's *History of the German People at the Close of the Middle Ages*; James Gairdner's *Lollardy and the Reformation*; Pollard's *Cranmer and the English Reformation*; McOrie, *Reformation in Spain*; Michelet, *Histoire de France* (vols. ix.-xii.); Baird, *Rise of the Huguenots*; Burnet, *History of the Reformation* (in England); Strype, *Memoirs of the Reformation*; Froude, *History of England* (first four vols.); Dixon, *History of the Church of England from the Abolition of the Roman Jurisdiction*; Worsley, *The Dawn of the Reformation*; Aubrey Moore, *Lectures on the History of the Reformation*, the relevant volumes of the *History of the Church of England*, edited by Stephen and Hunt, of the *Political History of England* by Hunt and Poole, of the *History of England*, edited by Oman; as well as Lingard and Gasquet on the Roman Catholic side; for Scotland the church histories by Lee, Cunningham, Grub, and MacLellan, Bellesheim being the standard on the Roman Catholic side; Seebohm's *Era of the Protestant Revolution*; Beard's *Reformation of the Sixteenth Century*; Smith's *Age of the Reformation*; the second volume (*The Reformation*, 1904) of Lord Acton's *Cambridge Modern History*; and *A History of the Reformation* by T. M. Lindsay (2 vols. 1906-7).

Reformatory and Industrial Schools. or Home Office schools, are defined for England and Wales by the Children Act of 1908 as schools respectively 'for the industrial training of youthful offenders,' and 'for the industrial training of

children,' juveniles of both categories being 'lodged, clothed, and fed as well as taught.' There are no state schools of the kind; the schools have been founded and are managed by bodies of private philanthropists, or by societies or religious bodies, or by local authorities. Control by the state is indirect and limited. The managers of a school desirous of receiving cases committed from the courts apply to the Secretary of State for a certificate, which is granted if on inspection the place be found suitable for the purpose. Should the subsequent conduct of the school at any time prove inefficient or unsatisfactory, the certificate may be withdrawn after six months' notice. Every certified school is inspected at least once a year by inspectors of the Children's Branch of the Home Office.

In the popular mind the distinction between reformatory and industrial schools is seldom as clear as it should be. A reformatory school can only receive a child between twelve and sixteen years of age after a recorded conviction for an offence punishable in the case of an adult with penal servitude or imprisonment, whereas a child under fourteen years of age may be sent to an industrial school without conviction. A proportion of the children have not been before a magistrate at all, but are 'voluntary cases'—troublesome children sent by friends or relatives or Poor Law Guardians, who pay a large proportion of the cost, or even the whole cost, of maintenance. Primarily industrial schools exist for the reception of children under fourteen who are found begging, wandering without proper home or guardianship, in the care of criminal or drunken parents, frequenting the company of thieves or prostitutes, living in brothels—in short, the victims of parental neglect whatever form it may take. A considerable proportion of the children, however, are committed for petty larceny, and indeed the neglect is often first brought to light when the child, as a direct result, commits a theft or other noteworthy offence. Essentially, however, industrial schools are for potential, as reformatory schools are for actual, delinquents. The single purpose of both alike is not punishment but training. Under the Children Act of 1908 managers of industrial schools may board out children under eight years of age with foster parents, but so far have availed themselves little of the power. Children are committed to reformatories for not less than three or more than five years, and must be discharged by the nineteenth birthday, though remaining under supervision up to that age however young when licensed out. Industrial school children must be licensed on or before attaining the age of sixteen, but remain under the supervision of the managers and are liable to recall up to the age of eighteen. Both classes of children commonly leave the schools some months before the completion of the full age, and some reformatory schools make a regular practice of licensing well-behaved boys after eighteen months' or two years' detention. The record of conviction often involves a life-long stigma in punishment of an offence committed by a mere child. It is hoped at an early date to get legislation to abolish this. Day industrial schools are for boys and girls whose homes, though not criminal or vicious, are so poor that the children require supervision and meals throughout the day. This type of school is, however, dying out.

The first so-called industrial school was really a junior reformatory established by the Middlesex justices in 1854, at Feltham, for convicted children between the ages of seven and fourteen years. But this was a comparatively late event in the history of the movement, a movement in which the state had taken no direct part further than the reservation

of Parkhurst Prison (1837) for boys under eighteen. The Marine Society had been founded as early as 1756 as 'an expedient to provide for poor boys who might become a nuisance.' The Philanthropic Society, now represented by the Reformatory Farm School at Redhill, was founded in 1788 'for the protection of poor children and the offspring of convicted felons, and the reformation of children who have themselves been engaged in criminal practices.' Pitt in 1793 brought in a bill to provide what would have been an industrial school, but it was rejected. In 1838 the Home Secretary was empowered to pardon boys sentenced to transportation or long periods of imprisonment on condition that their guardianship was undertaken by the managers of specially provided schools; the Treasury was authorised to contribute to their support. Here we have the beginning of the system, which still obtains, of government-supported voluntary schools. Many of them grew out of the ragged school movement, a school of industry at Dundee, and Dr Guthrie's school at Edinburgh (1846) being among the first. (See *RAGGED SCHOOLS*.) In 1846 a bill was brought in for the establishment of reformatory schools. This also failed to pass. But the public conscience was growing increasingly sensitive to the scandal of committing young children to the common gaols, and in 1851 a conference was held in Birmingham, of which the outcome was the foundation of several schools and the encouragement of renewed efforts in the House of Commons. The first Reformatory Act was passed in 1854, four years later than the first French Act. It enabled schools to obtain a certificate dependent on a satisfactory report from the inspector of prisons, and authorised the commitment of children under sixteen after not less than ten days' preliminary imprisonment, a condition not abolished till 1899, and not even optional up to 1893. In 1857 forty-four schools had been certified, and the first inspector was appointed. An Industrial Schools Act was passed in this year, and an act of 1866 amended and consolidated the law relating to the schools, and practically unaltered, remained in force until 1908. Day industrial schools were established by the Education Act of 1876. Several departmental committees have made important suggestions for increasing the efficiency of the work, among others that the Board of Education should assist with the inspection of the reformatory and industrial schools department. This recommendation has been adopted. The passing of the Education Act (1918), the findings of a department committee on salaries and conditions of service (1919), and a radical change in the system of Treasury grants (1920) closed an important decade in the history of the schools, and involved more progress in the treatment of the delinquent child than any legislation since the act of 1866.

The schools themselves vary considerably in character. Generally the buildings are well situated and suitable. Some were built for the purpose, but many are old residences adapted. There is now only one training ship, the *Cornwall* in the Thames. Experience has shown that for the younger boys at any rate the old training ships were unhealthy. Of nautical schools which have succeeded former ships there remain the *Haswell* (*Akbar*) and *Farnworth* (*Clarence*) reformatories, and the National Nautical (*Formidable*) and *Wellesley* industrial schools. For some years there has been a decrease in the number of boys leaving the schools to go to sea. As a result of their conviction ex-reformatory boys, known as such, are not accepted for the Royal Navy except in the capacity of stokers, but there is no restriction on their enlistment in the Army.

Though some of the children committed to re-

reformatory and industrial schools are of a fine type, many are mentally and physically below the normal of their class; but with improved hygiene, more generous dietaries, and the reduction of household drudgery formerly considered beneficial to character, a high standard of health has been attained. The death-rate of children in these schools is now less than that for children of the same age-periods for the country as a whole. Several special schools are certified for the reception of mentally deficient, ophthalmic, and other defective committed children, and there are schools for girls whose vicious tendencies or deplorable experiences render them unsuitable for association with others.

There are differences of opinion among managers as to the relations which should be maintained between the school and the parents. A few try to sever the connection, while others keep in close touch with their children's homes, allow frequent visits and letters, visit the homes, permit well-behaved children to spend a week or a fortnight at home once or twice a year if a sufficient standard of cleanliness and decency is maintained, and make it their aim to raise not only the child but the family, with a view to eventual reunion under respectable conditions. This latter course has been strongly advocated by the Home Office, and with marked success. When a child is committed to a school the magistrate usually makes an order for the parent to contribute a small weekly sum towards his maintenance, but such payments only amount to about 5 per cent. of the income of a school. Until recent years, in the majority of schools the children were expected by their labour to contribute largely to the cost of maintenance and also perform the whole of the domestic work of the school. Now, however, the provisions of the Education Act, 1918, are enforced, and the children under fourteen years of age receive much the same type of education as the child in the public elementary school—indeed, in some instances the children attend the local school with excellent results. In addition to this most industrial schools have well-equipped manual-instruction shops and also give valuable training in gardening, instrumental music, and in the girls' schools domestic subjects. The reformatories give, in addition, definite vocational training in farming, gardening, carpentry, and engineering, and provide educational classes of a wide scope. The training of girls has in recent years been greatly improved by the reduction in non-educational laundry-work, and the appointment of resident or visiting domestic science teachers. From a few institutions specially clever girls are sent to attend secondary schools, commercial courses, and trade schools, while shorthand and typewriting are quite commonly taught on the premises.

The value of sports and field games has long been recognised in the schools, and in boys' and girls' schools alike the facilities for indoor recreation and the pursuit of hobbies are excellent. The notion, still quite common among the public, that the schools are practically junior prisons is not justified. Bolts and bars have practically disappeared, and, as a result, absconding; and the best schools not only grant home leave, but freely allow boys or girls who have not forfeited the privilege by misconduct to go out by themselves at frequent intervals. Nearly all schools, too, provide for a summer holiday, generally at the sea.

Discipline in the majority of schools is maintained largely by systems of privileges and rewards. All forms of punishment are defined and safeguarded by strict rules, and every case has to be reported quarterly to the Home Office.

When the time approaches for a boy or girl to

leave a certified school on licence, it becomes the duty of the managers, commonly delegated to the superintendent, to find suitable occupation, and arrange for residence either with parents or friends, with employers, or in lodgings or hostels. Some schools have certified auxiliary homes in which homeless children can lodge until they become self-supporting, and to which others may return for holidays, or when changing situations. A government grant of 3s. per week, up to the age of eighteen, is made for each child when necessary, and many local authorities supplement this. A common form of disposal for boys, other than those from the nautical schools, is to farm service or army bands. An increasing number are also placed in skilled trades. For girls domestic service, until very recent years, was practically the only outlet, but now the more advanced schools are turning out a few teachers, shorthand typists, clerks, and nurses.

The managers of schools generally keep in close touch with their boys and girls for three years after they leave the school, and this 'aftercare' is now a well-established and important feature of the work. Those who are not doing well may, with certain limitation as to age and period, be recalled to the schools and given a fresh start.

The results are difficult to estimate, but the turns show that about 90 per cent. do well. The schools are seriously handicapped in their work from their inability to say too much of their successes. Obviously they cannot advertise the fact that a well-known public servant was educated in a certified school, but, on the other hand, if a boy or girl trained in a Home Office school in years to come is convicted of crime, the system is discredited by the prominence given by the press to the fact that he or she is an ex-inmate of a certified school. Probably the number who become good citizens is in the same proportion as from any other type of school.

At the present time a Departmental Committee is considering the whole question of juvenile delinquency, and will, no doubt, make many recommendations to facilitate and improve the training and disposal of these young people.

Detailed information concerning the working of these schools can be obtained from the Annual Reports of the Children's Branch of the Home Office.

The departmental committee on the schools in Scotland, which reported in 1914, urged that they should be transferred to the control of the Scottish Education Department, a recommendation vigorously supported by the Home Office Department. The transfer was effected in 1920.

Throughout the British empire, even in quite small colonies, reformatory acts have been passed, and schools for young delinquents have been provided, in many cases, by government. Training ships have been discarded. Speaking generally, the colonial administrations have viewed with disavour the herding of children in big barrack institutions, and have adopted, whenever practicable, the principle of boarding out. In general, also, they extend the age of criminal minority.

The United States possessed a very large number of reformatory institutions for boys and girls, but many have been closed owing to the development here, too, of the boarding-out system and general recognition of the disadvantages of institutional life. Many of the older institutions have been reorganised as cottage colonies—the only system now approved by public opinion. Thus the state agricultural and industrial school of Rochester, which, since 1884, had replaced the House of Refuge founded in 1824 (the first reformatory school in the world established by law), was reopened at Industry, New York, in carefully classified colonies of twenty-

five children. The Glen Mills schools, Delaware, again, are on the cottage system. There is no Federal law concerning reformatory and industrial schools, so each state has its own laws and its own schools. But the general principle is the same in each—a recognition of the fact that the children are not in the schools for punishment, and an endeavour that life should be as free and home-like as possible.

In Belgium the schools belong to the state. The technical training is very advanced, but the régime appears too prison-like. Denmark has both state and certified voluntary institutions for delinquent children. In France no conviction can be recorded against a child under thirteen, the limit of criminal minority is eighteen, and young persons may be detained or kept under supervision up to the age of twenty-one. For sentences of less than six months a child is sent to a juvenile prison, for those of over six months up to two years to a state reformatory (Colonie Pénitentiaire), and for sentences of over two years to a senior reformatory or 'correctional colony.' In the state reformatories parental rights are forfeited. The institutions for girls are known as Ecoles de Préservation. In addition to the state reformatories there are various voluntary institutions, one of which, Mettray, is the oldest reformatory in Europe. As in most continental establishments of the kind, corporal punishment is absolutely forbidden. In Germany the system is one of voluntary management, with maintenance entirely provided out of the public funds of the state and the province. Das Rauhe Haus, founded in 1833 near Hamburg, was one of the earliest models for industrial schools; it is conducted on the cottage system. The reformatory at Nordhansen, Saxony, founded in 1910, is also on cottage lines, and in 1913 was described as the best reformatory in existence; it is splendidly equipped, and every endeavour is made to approximate to family life, and to give all possible freedom and responsibility; a house-mother as well as house-father is present in each boys' cottage. Throughout Germany supervision of ex-inmates continues up to twenty-one years of age. In Holland by law of 1901 imprisonment was abolished for children under eighteen, and only those over fourteen might be committed to a school for a first offence. In most cases detention is only for six months or a year, but it may continue up to the age of twenty-one. In Hungary, Aszód, the first of several state reformatories, was opened in 1884. This institution and Kassa (now in Czechoslovakia), opened in 1900, became distinguished by their efficiency as schools of arts and crafts, agriculture, and horticulture. Wages, amounting to one-third or one-half of the value of work done, were paid. Árpád was established in village form. In addition to these state schools, others of a voluntary character were founded by the National Child-Protection League, which had in view a system of graded homes, with promotion from one to another. The League also adopted responsibility for the after-care of children from the state reformatories, a system being devised whereby owners of industrial undertakings provided well-managed hostels for old boys from the schools. In Italy the system is one of state and voluntary schools. Technical instruction reaches a very high level, and ex-inmates, in high percentage, are placed in the trades they have learnt. Wages are paid within the institution to boys who have acquired sufficient skill to earn them. In Norway the controlling authority is the Education Department. Some of the schools, being on otherwise uninhabited islands, are able to afford almost unrestricted liberty. In Russia the first schools were voluntary, but under the control of the Minister of Justice. Many prisons had also

special sections for children who were there kept under much the same régime as in the reformatories. In 1909 the institution of government reformatories was sanctioned. In Sweden the

public and private, the only such institutions were fifteen to eighteen. In Switzerland there is no Federal system, but some cantons manage reformatories, and there are also various small private institutions corresponding to industrial schools.

In 1908 Japan passed a law concerning the establishment of industrial schools; there is no corporal punishment. A reformatory at Gezireh in Egypt is said to be second to none in the world in equipment and in efficiency of technical instruction, but is described as being unduly penal in character. See also JUVENILE OFFENDERS.

Reformed Churches. A term employed in what may be called a conventional sense, not to designate all the churches of the Reformation, but those in which the Calvinistic doctrines and still more the Calvinistic polity prevail, in contradistinction to the Lutheran (q.v.). The influence of Calvin proved more powerful than that of Zwingli, which, however, no doubt considerably modified the views prevalent in many of these churches. The Reformed Churches are very generally known on the continent of Europe as the *Calvinistic Churches*, whilst the name *Protestant Church* is in some countries almost equivalent to that of *Lutheran*. One chief distinction of all the Reformed Churches is their doctrine of the sacrament of the Lord's Supper, characterised by the utter rejection not only of transubstantiation, but of consubstantiation; and it was on this point, mainly, that the controversy between the Lutherans and the Reformed was long carried on. See LORD'S SUPPER, and SACRAMENT. They are also unanimous in their rejection of the use of crucifixes, and of many ceremonies retained by the Lutherans. Churches belonging to the Reformed group are those of England (in some respects) and Scotland, some churches of various parts of Germany, the Protestant Churches of France, the Netherlands, Switzerland, Hungary, Poland, &c., with those in America which have sprung from them.

Reformed Episcopal Church (otherwise called the Reformed Church of England) was founded by the Right Rev. Bishop C. D. Cummings, D.D. (assistant bishop of Kentucky), in the United States in 1873. Its relationship to the Church of England is derived from the possession in its holy orders of the same historical succession, though the See of Canterbury, common to both Churches. In orders, worship, and doctrine it takes outside the Established Church the position of the Evangelical party within. This Church has spread widely, and is now working in the United States, Canada, India, and England.

Reformed Presbyterians. See CAMERONIANS.

Refraction. When a beam of light, travelling in a transparent medium, impinges obliquely upon the surface of another transparent medium, what occurs in the vast majority of cases is that a part of it is reflected (see REFLECTION) and a part of it enters the second medium, but in so doing is *refracted* or bent out of its former course. If, for example, the light travel in air and impinge obliquely upon glass, the course of the refracted portion is bent so that the refracted light travels more directly or less obliquely through the glass; and, conversely, if the light travel in glass and impinge upon an air-surface, the portion which is refracted into the air will travel through the air more obliquely with respect to the refracting sur-

face than the original light had approached it. The law of refraction was discovered by Snell in 1621, and is the following: the refracted ray is in the same plane with the incident and the reflected ray, and is therefore in the *plane of incidence* (see REFLECTION); and the sine of the angle of incidence bears to the sine of the angle of refraction a ratio which remains constant, for any two media, whatever be the angle of incidence.

In fig. 1 a ray, AO , impinges on a denser medium at O ; the angle of incidence is AON (ON being at right angles to t' : refracting surface); the refracted ray, instead of going on towards a' , is bent so as to pass through A' . Draw a circle cutting AO and OA' in c and c' ; draw ed and $c'd'$ at right angles to NN' : these lines, ed and $c'd'$, are, for the radius Or , the sines of the respective angles AON and $A'ON'$. These sines bear to one another a certain proportion, ascertained by measurement; let it be $3:2$; then Snell's law is that any other ray, say from B , will be so refracted that the sines, similarly drawn, will bear to one another the same proportion of $3:2$. Between air and water the ratio of these sines is almost exactly $4:3$; between air and crown-glass it is nearly $3:2$. Now observation shows that light passing from water into crown-glass is so refracted that the sines have the ratio $\frac{3}{2}:\frac{4}{3}$, or $9:8$, so that the rays are less bent than when they pass from air into any of these media.

Fig. 1.

The ratio of these sines when *air* is one of the pair of media involved is called the *refractive index* of the other medium; thus, water has, for sodium monochromatic light and at 18°C ., a refractive index of 1.3336, and crown-glass one of 1.5396; and the ratio of these refractive indices, ascertained with respect to air, governs the ratio of the sines, whether air be one of the pair of media experimented on or not. A direct consequence of this is that, if light pass successively, say, through air, glass, and water, the ultimate deviation will be the same as if the glass had been absent; and so for any number of intervening terms, it being always assumed that the bounding surfaces are parallel to one another; and if a parallel beam of light, passing through air, come to traverse any number of parallel refracting-surfaces, and if it regain the air, it will be found to travel parallel to, if not directly in, its original course.

The observed fact that light is differently bent in its course by different refracting media shows that there is a difference between bodies in their power of receiving light through their bounding surfaces. Newton, in accordance with his corpuscular theory (see LIGHT), interpreted this as showing that when the luminous corpuscles come very near the surface

of a denser substance they are as it were jerked or made to swerve out of an oblique path and hurried in by the attraction of the denser substance so as to enter that substance more directly; and that when the light quits the denser substance it is retarded by a similar attraction. The consequence of this would be that light would travel in the denser medium perhaps not appreciably faster than in air, but with a mean velocity certainly not less. On the undulatory theory, however, refraction is a necessary consequence of a slower travel of ether-disturbances in the denser medium.

In fig. 2 A is a plane wave-front, advancing obliquely towards B , the surface of a denser medium. At the end of a certain time the wave-front is at A' ; after an equal interval it is at A'' . During the next equal interval a gradually diminishing breadth of the wave is traversing the original medium with the original velocity; but a steadily widening portion of the wave-front enters the denser medium and is there hampered. At the end of the interval the aggregate disturbance, that is to say, the wave-front, will be found to have swung round into the position and direction represented by α , just as a line of soldiers would tend to do on obliquely entering more difficult ground. During the next equal interval the wave-front advances parallel to itself, but traverses smaller distances in equal times, so that aa' is less than AA' . To this explanation it is essential that in optically denser media light should travel more slowly; and it has been absolutely established that this is the case. Optical density, so called, does not, however, always coincide with mass-density: bisulphide of carbon, which is lighter than glass, has for sodium light a refractive index of 1.63, while crown-glass has an index about 1.5, and flint glass one about 1.6. If the course of any ray between any two points in the two respective media be studied, it will be found that no other path between the two points could have been traversed in so short a time.

If we go back to fig. 1, and assume the rays to pass from A' , B' , &c. towards O , we find the rays emerging from the denser medium more nearly parallel to SS' : a ray from C' , so far as it is refracted at all, emerges parallel to SS' ; and for

Fig. 2.

rays approaching O from points between C and S' the construction for the refracted ray becomes impossible. The angle $C'ON'$ is the *critical angle*, beyond which there is no refraction, but total reflection (see REFLECTION). This angle is such that its sine is equal to $\frac{1}{\mu}$, where μ is the ratio between the refractive indices of the denser and

the rarer medium. For water and air it is, for sodium monochromatic light, $48^{\circ} 27' 40''$. Where this ratio μ (the 'relative index of refraction') is high, this critical angle is small and total reflection is well marked, as in the sparkle of the diamond.

When a spherical wave impinges on a plane surface it travels in pseudo-hyperboloids, the centre of curvature of the central portion of which is, as regards its distance from the refracting surface, farther away than or nearer than the centre of the sphere in the ratio of the refractive index of the second medium to that of the first. An eye within a rarer medium will thus see the image of a point situated within the denser medium as if it were nearer than it really is; hence a stick appears bent when partly immersed obliquely in water; and, owing to differences in the amount of refraction at different angles, the bottom of a tank looked down upon appears sunk in the middle.

In fig. 3 light starts from a point X, and impinges directly upon a spherical surface of a denser medium; the centre of curvature of the spherical surface is at C. During a certain interval of time the front of the wave advances from A' to A; during the next equal interval it would, but for the denser medium, have been at B'D'. It has not, however, got so far as R in the time; the central part of the wave-front has only got as far as R', where $AR : AR' :: \mu : 1$. Any non-axial ray, such as XP, which would have reached Q, can only have originated a disturbance at P', which would have travelled from P' in some direction to a distance not equal to P'Q, but to P'Q reduced in the same

Fig. 3.

ratio of $\mu : 1$. We might then, knowing μ , the relative index of refraction of the denser medium, draw, with centre P and radius = $PQ \div \mu$, an arc of a circle; the disturbance will have got to some point on that circle. Doing the same for all the P's, we have a series of circular arcs which may be connected by a line drawn so as to touch them all. This line will be a curve; and it will, for some distance from the axis, coincide very nearly with the arc of a circle whose centre is at X', so that the wave-front will travel in the denser medium approximately as if it had originally come from X'. The relation between the distances AX, AX', and AC is given by the formula $\mu_1/AX' - \mu_0/AX = (\mu_1 - \mu_0)/AC$, where μ_0 is the refractive index of the original, and μ_1 that of the refracting medium. For example, let $\mu_0 = 1$ (air) and $\mu_1 = 1.5$ (crown-glass); $AC = 2$ inches; $AX = -1$ inch (i.e. the source of light is one inch to the left of A); then $1/AX' + 1/1 = \frac{1}{2}$; whence $AX' = -2$, or the light travels in the denser medium as if it had come from a point 2 inches to the left of A. If the wave-front be plane as it approaches A, that is equivalent to $AX = -\infty$ or $\mu_0/AX = 0$; whence AX' is equal to $+6$, or the light converges on a point in the denser medium 6 inches to the right of A. If, however, a plane wave-front approach A in the denser medium, that is equivalent to $AX = +\infty$; but, as the original medium is now the denser one, $\mu_0 = \frac{1}{2}$ and $\mu_1 = 1$;

whence, by the formula, $AX' = -4$, and the convergence is on a point 4 inches to the left of A. These distances of the points of convergence for plane waves, at $-4 (=f)$ and $+6 (=f')$ from A, are the Principal Focal Distances for the curved surface and the media in question; and they bear numerically the same ratio to one another as the refractive indices do; from which, together with the previous equation, we get $-f/AX + f'/AX' = 1$; which shows, still keeping to our numerical example, that when the object lies at a greater distance than 4 inches to the left or 6 inches to the right of A, the image is a real one on the opposite side of A; whereas when it is at a less distance from A, X and X' are on the same side of A, and the image is virtual. X and X', thus determinable when one of them is known, are *conjugate foci*; and they are interchangeable, so that an object at either will produce an image, real or virtual as the case may be, at the other.

The refracting medium may not be of indefinite extent, but may be bounded in the path of the light by another surface. If the two surfaces be both symmetrical round a common axis, we have a Lens (q.v.); and, by repeating our calculations of the refraction at the second surface as if the image produced by the first were itself an object, we arrive at the formulae given in the article on LENSES.

If a parallel beam of light enter one plane surface and be there refracted and emerge by another which is not parallel to the first, we have the essentials of a Prism. Assume the incident light to be monochromatic; then fig. 4 shows the incident beam SP taking the course SPQR.

The elements of the problem are, μ being the relative index of refraction of the prism: (1) $\mu \sin QPn' = \sin SPn$; (2) $\mu \sin PQn' = \sin RQm$; (3) angles $QPn' + P'Qm' = \text{angle } A$, by the geometry of the figure; and (4) angles $SPn + RQm = \text{angles } A - mn'n$, this last being the Deviation produced by the prism. These four equations contain seven terms; and it is sufficient to measure three of these, say the angles A, SPn , and $mn'n$, in order to ascertain the rest, including μ , the relative refractive index of the prism for the particular monochromatic light employed. If, however, the light employed be not monochromatic but mixed, as ordinary daylight, we find that the prism sends each wave-length—each colour sensation-producing component of the daylight (see COLOUR)—to a different place, and thus produces a Spectrum (q.v.). Each wave-length has its own μ and its own deviation: the more frequent and therefore shorter waves being the more refrangible by a given piece of glass and travelling the less rapidly within it.

If in fig. 4 the prism be turned so that S and R lie symmetrically with reference to the angle A, the deviation is then a minimum; and in that position of minimum deviation a monochromatic beam, divergent from S, will come to focus at R. In examining the spectrum of light from a source S it is necessary to turn the prism so as to ensure sharpness by producing this minimum deviation for each part of the spectrum in succession. When the deviation is a minimum everything is symmetrical: $SPn = RQm$; $QPn' = P'Qm'$; whence, by equations above, $SPn = \frac{1}{2}(A + mn'n)$, and $QPn' = \frac{1}{2}A$; whence $\mu = \{\sin \frac{1}{2}(A + mn'n) \div \sin \frac{1}{2}A\}$, which determines μ , when A (the angle of the prism) and $mn'n$ (the deviation) have been measured. The refractive indices of liquids and of

Fig. 4.

gases are determined by enclosing them in hollow prisms of glass whose walls are made of truly parallel glass; the parallel glass produces no deviation. In liquids the angle of total reflection or 'critical angle' may also be readily measured; then the sine of this angle $= 1/\mu$. The refractive index varies with changes of density, $\mu - 1$ being approximately proportional to the density; and it bears certain intimate relations with the molecular constitution of the refracting matter.

As to why ether-disturbances of differing wave-lengths are differently refracted in such a medium as glass, we may adopt two main lines of inquiry. First, with v. Helmholtz, we may consider the vibrating ether as putting the atoms in a molecule out of place and expending energy in so doing; and the atoms as being so pulled, but also as being elastically returned to the molecule, with an absorption of energy by friction or damping; then these assumptions lead to the conclusion that the refractive index for a particular wave-length depends upon the relation between that wave-length and the natural period of vibration of the atoms. Second, in terms of the modern electromagnetic theory of light, we may consider the rapidly reversing electric forces in the medium as setting in motion charged electrons or groups of electrons, which themselves have positions of equilibrium with reference to the atoms to which they belong, and which therefore vibrate, with an absorption of energy by friction or damping; and also consider the electric current at each point to be partly due to the forces in the field and partly to the actual transport of charged electrons; then these assumptions lead to similar conclusions: similar, not identical in detail, but rather better in conformity with experimental observations. In all these cases we find ourselves obliged to assume that the bend of the rays is not abrupt at the reflecting or refracting surface, but involves an exceedingly thin superficial film or skin.

The general result is that, where we have an absorption-band in the spectrum, on the red side of it the refrangibility increases as the wave-length diminishes, and that more and more rapidly until at the absorption-band a high maximum is reached; but on the other side of the absorption-band the refrangibility first presents a low minimum, then rapidly increases, and then increases more and more slowly, as the wave-length continues to diminish. In so-called normal dispersion the determinant absorption-band is outside the visible spectrum; but its presence is revealed by the want of coincidence, as regards the distribution of colours, between the prism-spectrum and the diffraction-spectrum, in which latter the deviation for each wave-length depends directly upon the wave-length itself; and for different substances (e.g. flint-glass prisms and crown-glass prisms) by a want of coincidence between the spectra produced by these respectively, even though these spectra be made of equal length. Besides,

Fig. 5.

in any substance not perfectly transparent, which no substance is, the local absorptions tend to complicate the distribution of colours in the spectrum. The irregularity of distribution of colour in the spectrum is called the *Irrationality of Dispersion*. If now we take two prisms, such as C (crown-glass) and F (flint-glass) in fig. 5, and pass a beam of light through; then, if the angles of these prisms be suitable, the rays dispersed by the one will be collected by the other, and there will on the whole be deviation without dispersion; but not absolutely so, on account of the irrationality of dispersion of both prisms, the effect of which is that a calculated ratio of angles and refractive indices which will

cause deviation without dispersion for any given pair of wave-lengths will, to a very slight extent in most cases, fail to do so for the other wave-lengths present in the mixed light transmitted through the system. By the use of three prisms three wave-lengths may similarly be achromatised.

Where the absorption-band is within the visible spectrum, remarkable consequences may follow—e.g. iodine vapour refracts red light more than blue, and blue less than violet; and fuchsine in solution refracts blue and violet light less than it does red, orange, and yellow, while it absorbs the rest. These are classified as phenomena of *anomalous dispersion*; but they are direct consequences of the laws of the relation of dispersion to absorption-bands. Further, in these cases of 'anomalous dispersion,' the substance generally has, in the solid form, a surface colour different from that seen through the solution.

DOUBLE REFRACTION.—The wave-surface developed when a disturbance originates at a point in a homogeneous medium, such as glass, is spherical in form. In uniaxial crystals (see CRYSTALLOGRAPHY) the disturbance travels with two wave-fronts, one spherical, the other ellipsoidal; and the two wave-fronts are coincident along the direction of the optic axis. Of such crystals some are *positive*, such as quartz and ice, and in these the sphere encloses the ellipsoid; in *negative* crystals, such as Iceland spar and tourmaline, the ellipsoid encloses the sphere. If then a beam of light, plane-fronted,

Fig. 6.

fall upon a slice of Iceland spar, the disturbance at any point such as A (fig. 6) is transmitted from that point in two portions: one portion is refracted, according to the principles of fig. 2 in article REFRACTION, as an *ordinary* refracted ray, O; the other is refracted in a way determinable by using in the construction, instead of the spheroid or arcs of a circle, the corresponding ellipsoid, or arcs of the appropriate ellipse, and it gives rise to the *extraordinary* refracted ray, E. The radius of the smaller circle is to that of the greater as $1:\mu$; the tangent to the greater circle, at right angles to XA, cuts SS' in T; tangents TO' and TE' to the smaller circle and the ellipse are also drawn so as to pass through T; the ray XA is deflected so as to pass through the points at which these tangents touch these curves; and thus there are two refracted rays, and an eye towards OE will see two images of X. The light in the ordinary ray O is found to be polarised (see POLARISATION) in a plane containing both the incident ray and the crystalline axis: the extraordinary ray E is polarised in a plane at right angles to this. In binaxial crystals the three optical axes are dissimilar, and the wave-surfaces become complex: there are two refracted rays. If a doubly refracting substance be put between two crossed Nicol's prisms (see POLARISATION), light passes; and

by this means it is found that many substances ordinarily not double refracting become so when exposed to unequal stress, as by pressure, heat, or rapid cooling.

CONICAL REFRACTION.—In certain cases light,

and in others a single ray, falling on the plate, becomes a cone inside the crystal, and emerges as a hollow cylinder. These extraordinary appearances were predicted from the wave theory of light by Sir W. R. Hamilton (q.v.), and experimentally realised by Lloyd. See Preston's *Theory of Light* (4th ed. 1912).

Refrigerants are remedies which allay thirst and give a feeling of coolness, although they do not in reality diminish the temperature of the body. The following are the refrigerants in most common use for internal administration: water, barley-water, dilute phosphoric or acetic acid, citric and tartaric acids taken in combination with bicarbonate of potash as effervescent draughts, ripe grapes, oranges, lemons (in the form of Lemonade, q.v.), tamarinds, chlorate of potash (ten grains dissolved in water, and sweetened with syrup, to be taken every third or fourth hour), and nitrate of potash, which may be taken in the same manner as the chlorate, or as *nitre-whey*, which is prepared by boiling two drachms of nitre in a pint of new milk; the strained milk may be given in frequent doses of two or three ounces.

Refrigeration, the artificial production and maintenance of low temperatures, is a modern art chiefly developed for the preservation of perishable foods. No doubt the observation that meat, milk, &c., keep longer in cool weather is a very ancient one, but the power to create favourable conditions at will involved a knowledge of the properties of insulating materials, availability in hot weather of ice, the only practical cooling medium, while the demand for such accommodation would only arise at a certain stage in material development. Frigorific mixtures for producing low temperatures were known in the beginning of the 17th century, and are still in use for scientific or minor purposes. In the early years of the 20th century a small ice-making machine was placed on the market, depending on the refrigerating effect of ammonium nitrate dissolved in water, and for making ice cream, the ice-and-salt method is still the principal one in this country. Fahrenheit, in working out his thermometer scale, obtained what he conceived to be the absolute zero from a mixture of ice and salt in 1762. Ice has been made in certain districts in India from a time that cannot be dated, by the atmospheric evaporation at night of water in shallow trays placed on an insulating layer of straw to cut off the earth heat. Practical refrigeration, however, for commercial purposes can hardly be said to have existed earlier than the middle of last century, although the idea of the refrigerating machine had been gradually developing in the previous hundred years.

The use of ice and of the refrigerating machine for cold storage went forward together. The first mild cured bacon in this country was produced by the aid of ice, and not so long ago many of the Danish factories used ice only, accumulating great stores in the winter time, and insulating the heaps with sawdust.

The refrigerating machine has everywhere been substituted, but ice still holds a very important place in refrigeration, and although large numbers of butchers, dairymen, fishmongers, and other small users have mechanical refrigerating plants, the greater number, especially of butchers and fishmongers, still depend on insulated chambers cooled

with ice, for fish and fresh meat, or ice and salt mixture for frozen meat. The refrigerating machine now holds the entire field for large scale work, and for the smaller purposes it is also gradually attaining the lead.

All refrigerating machines are founded on the transformation of energy involved in the latent heat of expansion or of evaporation. When a solid changes into a liquid, or a liquid into a vapour, a considerable amount of heat is absorbed, or, in the old phrase, becomes latent. In reality the heat has been transformed into the mechanical energy necessary to change the state of the material. In refrigerating machines the expansion or evaporation is usually effected or assisted, not by the application of heat, but by mechanical power, and the refrigerant is, therefore, compelled to find from its surroundings the heat necessary to the change of state, and in this way the refrigerating effect is produced.

Refrigerating machinery is divisible into several distinct classes, in accordance with the nature of the refrigerant and the refrigerating process made use of.

When air is compressed, heat is liberated in amount proportionate to the degree of compression. If this heat is removed with cooling water, and the compressed air allowed to expand, and at the same time made to do mechanical work, the heat required to maintain it in its original state is reabsorbed from the surroundings, and refrigeration is produced. This is the principle of the cold-air refrigerating machine, which, as perfected by Bell-Coleman, Lightfoot, and Haslam, brought over the first three successful cargoes of frozen meat from Australia in 1880. Owing to the fact that the air is merely compressed—not liquefied—the cold-air machine requires an excessive amount of power, and this, together with some difficulties connected with the freezing of the moisture in the air, has led to its supersession, except for some purposes where costs do not count.

The vacuum machine for ice-making was invented by Dr Cullen in 1755, but the first practical machine was Edmond Carré's, developed about a hundred years later. In the vacuum process, ice is made by the rapid evaporation at reduced pressure of a portion of the water being frozen. The pressure must be lowered sufficiently to enable the water to boil at, or under, freezing-point, and this is brought about by the action of an air-pump, aided, in Carré's machine, by an absorbent—sulphuric acid. Although vacuum plants have been made of considerable capacity, they have not come much into use, as they are expensive and troublesome to work, and the ice produced, which is opaque, or rotten, does not find favour among users. Small plants of this type are still exported in fair numbers to hot countries, and hand-driven sizes turn out a pound or two of ice in a few minutes.

The absorption system was the invention of Ferdinand Carré, a brother of Edmond, and the first machine was produced in 1858. The laboratory type consisted of two iron cylinders joined overhead by an arched iron pipe. One cylinder was about half full of strong ammonia solution. When heated, ammonia gas distilled off and was liquefied in the other cylinder, which was placed in cold water. After the distillation of gas was completed the process was reversed, the distilling cylinder going into the cold water, and that containing liquefied ammonia into the water to be frozen. The liquid ammonia under high tension rapidly distilled back, and dissolved again in the water of the distilling cylinder, while the heat, becoming latent during evaporation, was withdrawn from the water being made into ice. This simple apparatus was not very efficient, as a considerable

amount of water distilled over with the ammonia gas into the liquefying cylinder.

On a large scale reversing was got rid of by the use of pumps, and means were devised for condensing the water vapour accompanying the distilled ammonia. The plan then consisted of the following elements: the generator, in which the ammonia solution was distilled, and the analyser or desiccator, in which the vapours from the generator met a descending current of ammonia liquor, which condensed practically all the water vapour and carried it back to the generator, while the purified ammonia gas passed on to the condenser where it was liquefied by its own pressure and cooling water in pipe coils. From the condenser the liquid ammonia went to the evaporator placed where the cooling effect was required, and the evaporated anhydrous ammonia was again dissolved in water in the absorber. This water usually consisted of the spent liquor from the generator, drawn off and pumped through an exchanger, where it gave up its heat to the current of cold ammonia solution from the absorber on its way back to the analyser and generator. And so the process went on continuously in a closed cycle. At the present time the absorption machine has still a certain vogue; large and much improved units are in existence, and where exhaust steam can be used as the heating agent, the process is said to be very economical, although somewhat extravagant, in cooling water. Certain small installations avoid the use of pumps by having two cylinders, each used alternatively, as generator and absorber, and these are useful where the vibration of running machinery would be objectionable.

The compression machine, which now carries the greater part of the burden of refrigeration, is founded on the principle that volatile liquids evaporated *in vacuo*, or, at diminished pressure, develop low temperatures. This observation was made by Dr Cullen in 1755, but the first practicable compression machine was that patented in 1834 by Jacob Perkins. It contained all the elements of the present day compression system, which are illustrated in the accompanying diagram. On one side is the evaporator with one or a series of

Diagram showing the compression system as applied to modern refrigerating machines.

pipe coils, in which the refrigerant is rapidly evaporated by the diminished pressure created by the compressor, which is really a pump. It is shown in a brine tank in which an unfreezable brine—generally a 25 per cent. solution of calcium chloride in water—is cooled to a low temperature by giving up its heat to the evaporating liquid in the coil. The cold brine is then circulated by a pump to where the cooling effect is required. The compressor delivers the evaporated refrigerant to a corresponding coil, or coils, shown on the other side of the diagram, which is called the condenser. This coil is placed in a tank through which is a circulation of cold water, and as the compressor condenses the vapour the heat absorbed in evaporation reappears, and is removed by the cooling

water, and the refrigerant is again liquefied. The ends of the coils are connected by a pipe, on which is a regulating valve, adjusted to give the correct flow of liquid refrigerant back to the evaporator, in accordance with the readings of pressure gauges placed on each side of the system. The process is thus continuous, and one charge of refrigerant would be everlasting, if leakages could be prevented.

Various refrigerants have been proposed, and used, in compression machines. Jacob Perkins made use of a volatile liquid obtained by the destructive distillation of caoutchouc. Ether was the refrigerant in the earlier machines, and the ether machine is still, to some extent, in favour in hot countries. Permanent gases, liquefied under pressure, are far more powerful refrigerants, and sulphur dioxide (SO_2), carbonic anhydride (CO_2), and anhydrous ammonia (NH_3), now almost monopolise the field, although methyl chloride has a certain limited and local vogue. The machines using these various refrigerants, although alike in principle, differ considerably in detail. SO_2 has a working pressure of 35 to 50 lb. per sq. inch, CO_2 750–1000 lb., and NH_3 140–150 lb., and the quantities required to be evaporated for a given refrigerating effect differ widely. SO_2 requires large cylinder space; CO_2 a very small; and NH_3 a medium pumping capacity. The widely different working pressures necessitate corresponding differences in construction; but, with well designed machines, the refrigerating output for a given amount of power is very nearly alike for each refrigerant. There are many types of compression machines—vertical and horizontal, single or double-acting, belt-driven or direct coupled to engine, and duplex and marine types: designed to economise space. The condenser may be of the submerged type as indicated in the diagram, or it may be of the atmospheric type which economises cooling water, or the double-pipe condenser which is coming into favour.

The refrigerating effect is conveyed in different ways to the insulated cold storage rooms and other spaces or apparatus to be cooled. The brine circulation, already referred to, is very commonly through grids of pipes on the ceiling or sides of the cold room, or the brine pipes may be stacked together in a separate room, and the air of the cold rooms circulated over them by a fan, or the brine may be exposed in cascades or films in the separate room to the action of the fan. Frequently the brine is eliminated, and the expansion pipes made to replace the brine pipes in the cold room, or built into a separate expansion air-cooler with a fan. The direct expansion method avoids many losses inherent in brine circulation.

Ice-making, which is now a large industry, is conducted in insulated tanks, usually of iron or mild steel, and the freezing is effected by a circulation of cold brine from the refrigerating machine, or the expansion pipes are placed in a compartment of the ice-tank, and the brine is circulated over them by a propeller. An ice-tank may be divided into spaces by hollow partitions in which the cold brine circulates, large slabs called plate ice being thus produced. If the water-freezing spaces between the partitions are divided by lateral partitions, cell ice is the product. The larger quantity of ice, however, is now made in galvanised sheet steel moulds hung in the ice-tank, and this is described as 'can' ice.

To get the ice clear and hard, agitating gear is required to eliminate the minute bubbles of air which separate as the water freezes, and which, if left, produce opaque or rotten ice. Ice adheres tenaciously to the partitions or cans, and is separated from the former by a circulation of warm

brine, while the latter are dipped in a tank of lukewarm water, the thin film melted in either case loosening the blocks.

The overseas trade in frozen meat is now of very large dimensions, and the shipping of fresh meat carried at just above freezing-point is increasing rapidly. Success in the business is secured by maintaining a constant temperature throughout, variations not exceeding one degree either way, with assistance on the longer voyages from a circulation of antiseptic gases.

Fresh meat is more valuable than frozen meat. Refrigerated butter, cheese, and hard fruits, such as apples, come over from Australia and many other places in large quantities, and Canadian and other colonial cheese is largely ripened in cold storage. The difficulties in the way of shipping soft fruits have not yet been overcome, but progress is being made in this direction. The freezing of fish for transport has now become practicable, the use of a very low-temperature salt brine having got over the tendency of all kinds of frozen fish to 'fall down,' or become flabby when thawed. Under the conditions the salt does not penetrate, and the fish throw out fresh. To handle these various goods, a network of public and private cold storages on an expensive scale is required at home and abroad.

Refrigeration has revolutionised the bacon trade. In the old way, curing could only be done successfully in the cold months of the year, and the bacon had to be made very salt to keep. The necessary low temperatures are now maintained continuously, and curing goes on throughout the year, so that bacon is produced only for quick consumption, and is mild cured and more palatable and nutritious than it used to be.

Brewers ripen their beer in cold storages, and they use quick chilling in conjunction with carbonating plant to 'condition' beer rapidly. Refrigeration is also an essential element in the manufacture of bakers' yeast.

In the preparation of lard and lard compound, revolving chilling drums, with an internal circulation of cold brine, are extensively used to produce a smooth waxy product without 'grain.' Oils, such as cod-liver, whale, neat's foot, &c., have their steams separated by exposure to a low temperature, and, in a similar manner, solid paraffin wax is separated from lubricating oils. Most of the large general stores now have far rooms, where far garments are kept, at a temperature of 40° F. or under, in the summer. At this figure the eggs of moths, which produce destructive grubs, cannot hatch out, and damage is thus avoided.

Refrigeration has been applied on a large scale with economical results to freezing out the moisture in air supplied to blast-furnaces. Another use is the solidifying of wet or boggy ground through which it is necessary to sink pits or wells, brine circulation through a ring of double pipes sunk in the ground being the method employed.

The air in some theatres and restaurants in Germany and the United States has been cooled by mechanical refrigeration in the hot weather. One rather curious application is the separation of optical glasses from the bituminous matrix in which they are held in grinding. The old method was to chip them out with a chisel, with an average of breakages of 10 per cent. Now the msh-room head with the glasses is dipped in cold brine, and the separation takes place by differential contraction with scarcely ever a breakage.

Regalbuto, a town of Sicily, 25 miles WNW. of Catania; pop. 12,500.

Regalia, the ensigns of royalty, including more particularly the apparatus of a coronation. The regalia, strictly so called, of England consist of the Crown (q.v.), the Sceptre (q.v.) with the cross, the verge or rod with the dove, the so-called staff of Edward the Confessor (made in reality for Charles II.), the orb of king and queen, the blunt sword of mercy called Curtana, the two sharp swords of justice, spiritual and temporal, the ampulla or receptacle for the coronation oil, the anointing spoon (probably the only existing relic of the old regalia), the armilla or bracelets, the spurs of chivalry, and various royal vestments. All these, with the exception of the vestments, are now exhibited in the Jewel-room in the Tower of London. See BLOOD (THOMAS), and Sir G. Younghusband, *The Jewel House* (1920).

The proper regalia of Scotland consist of the crown, the sceptre, and the sword of state. The sceptre is of the time of James V.; the sword was a present from Pope Julius II. to James IV. in 1507. During the Civil War the regalia were removed by the Earl Marischal for safe custody from the Crown-room of Edinburgh Castle, their usual place of deposit, to his castle of Dunnotar (q.v.); and from the Restoration to the Union the regalia continued to be kept in the Crown room as formerly. From the Union till 1818 the regalia remained locked in a chest in the Crown-room; but in 1818, an order being obtained from the Prince-regent, the chest was broken open, and the crown, sword, and sceptre are now in the charge of the officers of state for Scotland, and are exhibited in the Crown-room. See Sir Walter Scott, *The Regalia of Scotland* (1819); and Douglas Barron, *The Defence of the Regalia* (1911), and *The Castle of Dunnotar* (1926).

Regelation. See ICE.

Regeneration, a technical term in biology for the regrowth of lost parts—e.g. arms of starfish, legs of crab, tail of lizard. The regenerative capacity tends to occur in those organisms and in those parts of organisms which are in the natural conditions of their life particularly liable to non-fatal external injury. See T. H. Morgan, *Regeneration* (New York, 1901).

In theology, regeneration is the spiritual change which passes on all men in becoming Christians; its necessity in some shape is recognised by all branches of the Christian church. As the condition of his becoming truly Christian, a man must pass from a state of nature to a state of regeneration, from a state in which he obeys the mere impulses of the natural life to a state in which a new and higher—a divine—life has been awakened in him. The words of Christ to Nicodemus: 'Verily, verily, I say unto thee, except a man be born again, he cannot see the kingdom of God,' are accepted as the expression of this universal necessity by the Christian church. It may be further stated that every branch of the Christian church recognises, although under very different conditions, the Holy Spirit as the author of this change. The change in its real character is spiritual, and spiritually induced. According to a large portion of the Christian church, however, the change is normally involved in the rite of baptism. In the Catholic view baptism constitutes always a real point of transition from the natural to the spiritual life. The grace of baptism is the grace of regeneration; and among the direct effects of baptism are (1) the remission of all sin, original and actual; (2) the remission of the penalties due for sin both temporal

and eternal; (3) the bestowal of sanctifying grace and the infused virtues; (4) the imprinting of an indelible 'character' on the soul; besides (5) making the recipient a member of Christ and the Church, and qualifying to receive the other sacraments. The usual Protestant doctrine of baptism is explained at BAPTISM; and see also GORHAM. Protestants hold for the most part that regeneration is a special, conscious process which takes place independently of baptism or of any other outward fact or ceremony. It implies a sensible experience—an awakening whereby men come to see the evil of sin and the divine displeasure against sin, and through the Holy Spirit are born again, put away their former evil life, and begin to live a new divine life. Technically Conversion (q.v.) is the action upon man, Regeneration the agency of God.

Regenerator Furnace. See GLASS.

Regensburg. See RATISBON.

Regent, one who exercises the power without having the name of a king. In a hereditary monarchy there are various circumstances which may necessitate the delegation of the sovereign power—as the devolution of the crown on a minor too young to be entrusted with the kingly office; the incapacity of the sovereign by illness, mental or bodily; and the case of absence from the realm. A regent under the title of Protector (q.v.) has often been appointed to exercise royal authority in the sovereign's minority, the latest instance in England being during the minority of Edward VI.; and regents and counsels of regency have been sometimes named by the sovereign to provide for the probable nonage of his heir. During the frequent absences of the first two kings of the House of Hanover in their continental dominions it was the practice to appoint regents or Lords Justices to exercise the powers of sovereign. See JUSTICES (LORDS). In 1788, when George III. became incapacitated by insanity from exercising the kingly office, it became a question whether his eldest son, then of full age, had a right to be regent, or whether the nomination rested with parliament. The chief political authorities of the time were divided in their judgment, but the king's recovery ended the discussion. On the return of the malady all parties were unanimous that the regency should be conferred on the Prince of Wales, and this was done by parliament. Regency Bills were passed in 1830, 1840, and 1910. For Regent in universities, see UNIVERSITY.

Reger, MAX, German pianist and composer, was born at Brand (Bavaria), 19th March 1873, the son of a schoolmaster, to whom he owed his first musical training. Later he studied under Hugo Riemann at Sondershausen and Wiesbaden (1890-95), and taught at Wiesbaden and Munich. In 1907 he became Director of Music at Leipzig University, and 1908-13 was professor at the Conservatorium. He died at Leipzig, 11th May 1916. Reger's output, mostly in the domain of chamber-music, was enormous. His compositions, of which his organ-music and songs are the best, never depart from classical traditions; they are marked by a wealth of harmony and polyphony, but frequently tend to over-complexity and obscurity. He published a *Modulationslehre* in 1912.

Reggio di Calabria (anc. *Ῥήγιον*, or *Regium Julium*), a seaport and archiepiscopal see of South Italy, stands on the Strait of Messina, 9 miles SE. of the city of Messina in Sicily. Manufactures of silks, scented waters, gloves, stockings, and caps—the last three made from the byssus of the Pinna (q.v.)—the cultivation of fruits, wine, and olives, and fishing are carried on. Pop. (1921)

29,421 (town); 159,516 (commune). The ancient *Regium* was founded by Greeks in the 8th century. It was taken and destroyed by Dionysius of Syracuse (387 B.C.), the Romans (270), Alaric (410 A.D.), Totila (549), the Saracens (918), and captured by Robert Guiscard (1060), Pedro of Aragon (1282), and the Garibaldians (1860). In 1783 it was ruined by an earthquake, and again totally destroyed in 1908. Various ancient remains have been found from time to time.—The province of Reggio di Calabria has an area of 1221 sq. m. and a pop. of 500,000.

Reggio nell' Emilia, a city and episcopal see of Northern Italy, 38 m. NW. of Bologna. The cathedral, dating from the 12th century, was reconstructed in the 15th and 16th. The Madonna della Ghiara has fine stucco decorations of the early 17th century. There is a museum with important palaeoethnological and prehistoric collections. The town is the centre of a rich agricultural district; cheese is made, and there are other manufactures. *Regium Lepidum* was probably founded by M. Aemilius Lepidus when the Via Aemilia was built in 187 B.C. In the 12th and 13th centuries it was a republic, but later passed under Modena. Pop. 83,000 (commune); 347,000 (province).

Regiam Majestatem, a collection of ancient laws bearing to have been compiled by order of David I., king of Scotland. The authenticity of the work has been controverted, a prevalent opinion being that it is a compilation from Glanville's *Tractatus*. Some authorities attribute the collecting of it to a commission of Edward I., others to an unknown author after the war of independence 14th century).

Regicides, the men who were appointed on the parliamentary committee to try King Charles I., but in a narrower sense the men, sixty seven in number, who actually sat in trial upon him. Of these only fifty-nine signed the death-warrant. After the Restoration the regicides were brought to trial on a charge of high-treason. Twenty-nine were condemned to death, but only ten were executed, nineteen, together with six others who were not tried, being imprisoned, most of them for life. More than twenty who were already dead were tried and condemned all the same, and Cromwell, Ireton, and Bradshaw, three of them, were executed and hanged at Tyburn, and then reburied at the foot of the scaffold. For regicides in a wider use of the term, see ASSASSINATION.

Regillus, LAKE, lay in Latium, to the south east of Rome, probably near the modern Fiascati; it is celebrated in the semi-legendary history of Rome as the scene (496 B.C.) of a great battle between the Romans and the Latins, fighting on behalf of the banished Tarquin, in which the latter were entirely defeated.

Regiment, a unit consisting of a number of squadrons of Cavalry (q.v.), batteries of Artillery (q.v.), or Battalions (q.v.) of Infantry. Regiments are spoken of at the time of the Armada, 1588, and as composing the force in Ireland, 1598. Charles I. and the parliament each raised regiments, all of which were disbanded at the Restoration, with the exception of the Lord-general's Regiment of Foot and his Life Guard of Horse. These two were re-engaged (1661) and form the present Coldstream Guards and Royal Horse Guards. In the same year a Scottish corps of 1700 men, which had taken service in France in the time of James I., returned to England, and was included in the British army as the 1st Foot. See ARMY. In 1693 was raised the 1st troop of Horse Grenadier Guards, and the 24 troop in 1702. These were re-formed in 1782 as the 1st and 24 Life Guards.

Regina, since 1905 capital of the province of Saskatchewan, is 356 miles west of Winnipeg, and 1885 feet above the sea. From its position on the Canadian Pacific and Canadian National railways, it is a great distributing centre, with large grain and lumber industries, and has rapidly increasing manufactures of agricultural machinery, &c. Notable edifices are the parliament buildings, post-office and city hall, and several of the churches. The town suffered terribly from a destructive cyclone on 30th June 1912, which wrecked many churches and public buildings. Pop. (1901) 2645; (1911) 30,210; (1921) 34,432.

Regiomontanus, the name given, from his birthplace, to the mathematician and astronomer Johann Müller, born at Königsberg in Franconia, 6th June 1436. He studied at Vienna and in Italy, and was called by Matthias Corvinus to his court at Buda; but in 1471 he settled in Nürnberg, where a learned and wealthy citizen, Bernhard Walther, subsidised him so as to enable him to construct mathematical and astronomical instruments and found a famous printing-press. The two laboured together at the correction of the 'Alphonine Tables,' and jointly published *Ephemerides 1475-1506* (1473), of which Columbus and other early navigators made much use. Regiomontanus not only worked at astronomy, but restored the study of algebra in Germany, extended the science of trigonometry, and published treatises on water-works, burning-mirrors, weights and measures, &c. He was summoned to Rome by Pope Sixtus IV. to assist in reforming the calendar, was made Bishop of Ratibon, but died at Rome, 6th July 1476.

Among his works are *De Doctrina Triangulorum* (1463); *De Quadratura Circuli* (1463); *Calendarium* (1473); *De Reformatione Calendarium* (1484); *De Cometa Magnitudine* (1531); *De Triangulis Omnimodis* (1533). See Ziegler, *Regiomontanus, ein geistiger Vorfahrer des Columbus* (1874).

Register of Voice. See VOICE.

Registers, PARISH. The place which parish registers now fill was formerly, but only in very small part, supplied by monastic registers, which, however, as a rule registered only deaths of important persons, so as to be able to tell when masses became due, and were usually confined to the families of founders, benefactors, and the like. Entries were also sometimes made in the missals of parish churches, and the monastic chronicles often contain necrologies, whilst mortuary rolls were regularly sent round from monastery to monastery. These were in effect the sole early public registers, but private necrologies were sometimes kept by the chaplains of great families—e.g. Friar Brackley has left one of the Pastons and Mawthys—and Burn (*History of Parish Registers*) mentions several entered in the flyleaves of private books of devotion. But it is mainly to the monastic cartularies and to inquisitions *post-mortem* and proofs of age that we must go for information on births and deaths of the pre-Reformation times.

It is probable that the injunction of Thomas Cromwell in 1538, ordering parish registers to be kept under the system now in vogue, was intended, like Edward VI.'s scholastic foundations, to meet one of the immediate difficulties involved in the suppression of the monasteries. Had this injunction been strictly acted on we should now be in possession of complete registers from that date onwards. But, perhaps owing to the fall, soon after, of the author of the injunction or to the general laxity of the incumbents, very little heed was taken of it, and the evil which this neglect entailed became so crying that Elizabeth in 1597 issued a stringent order that not only should

the registers be better kept, but copies of them should be yearly sent to the bishop of the diocese, an order which in 1812 was supplemented by an act enjoining the preservation, arrangement, and indexing alphabetically of the names on the registers. But nothing has been of much value against the incorrigible neglect of the incumbents and bishops. Early transcripts are practically non-existent, and even those of the 18th century are most imperfect. In the returns of the population abstracts in 1801 it was discovered that amongst 11,000 parishes in England 812 registers dating from 1538 alone existed, and later returns in 1834 showed that even that small number had decreased through the negligence of the clergy in the interval. These last returns give full details as to the date of the commencement of each register in England.

Such registers often contain much valuable information as to the history of the parish, many incumbents slightly overstepping their strict duty by putting down noticeable and curious incidents which occurred from time to time.

Registration may be described as a record of certain legal facts or transactions inserted in a book called a register and kept at a public office. Its main purposes are to preserve an authentic account of matters of public concern, to secure for them a means of publicity, and to simplify the methods of proving them. In all civilised states the registration of certain facts or transactions has been deemed necessary. In Rome public books of record existed from an early period. In later times a practice of inscribing in a public record copies of documents dealing with transactions affecting private interests came into use. The emperor Leo, recognising the existence of this practice, adopted it as a method of validating gifts; and in the later Roman empire a system of registration (*insinuatio*) for gifts was fully established and rigorously applied. Under Justinian a gift exceeding a certain amount was, if unregistered, void as to the excess. In modern systems of law a system of registration is employed in many different departments and for many various purposes. Thus in England many statutes provide for the registration of matters of public concern and make duly authenticated extracts evidence of the contents of the register. Whenever indeed it is the duty of a public official under English law, either at common law or by statute, to record certain facts in any book which is intended to be kept as a register to be referred to ever after, the book is admissible in evidence to prove not only that such official made those entries but also that the facts which he recorded are true.

Registration of judicial proceedings.—In all countries the decrees of courts of justice, civil and criminal, are registered. In England registrars are attached to the Privy Council, the several Divisions of the High Court and the County Courts. In the King's Bench Division the duties of registrars are performed, except in its bankruptcy jurisdiction, by the masters. The registrars record the proceedings of the court at each stage up to the final judgment, and with them affidavits, pleadings, &c., are filed. Probates of wills and letters of administration, both of which are really judicial proceedings, are recorded either in the principal registry of the Probate Division of the High Court or in one of the district registries. When a will is proved the original must be deposited in the registry of the Court and a copy thereof on parchment, called the probate copy, is made out under its seal and delivered to the executors, together with a certificate of its having been proved. The probate is conclusive as to what the will is. It can only be corrected on application to the Probate Division.

Registration of title to land and of deeds affecting land.—There are two main systems of public registration in respect of land—registration of title and registration of deeds. A register of title is an authentic and self-explanatory record of the state of the title to the land registered in it. A system of state registration of title to lands is in operation in many countries. Under this system the state establishes and maintains a register in which the names of the persons who own, or have proprietary interests in, particular lands are entered and in which are recorded all changes in the ownership of the land and all dealings with interests in it or burdens affecting it. The Torrens system of registration of title to land, introduced in South Australia in 1858 at the instance of Sir Robert Torrens, the first premier of the colony, was subsequently adopted in its main features in all the other Australian colonies as well as in Canada, and is the foundation of the system set up in England by the Local Transfer Acts 1875 and 1897. Where a system of state registration of title is fully operative, entry on the register constitutes the only title to land, and dealings with the land are ineffectual unless noted on the register. The principal objects of such a system of state registration are to obtain a public record of the ownership of land, to secure certainty of title in land, and to facilitate its transfer. Distinct from the system of registration of title is the system of registration of deeds affecting land. Under this system the register contains merely a statement of the deeds affecting the land, generally giving either a transcript or an epitome of each of these deeds. Such a register, while it afforded a measure of protection to the persons concerned, leaves them to draw their own conclusions as to the effect of these deeds on the title to the land, and does not import any guarantee of title.

In England registration of title was first introduced as a voluntary system by the Land Registry Act, 1862. The system instituted by that act did not prove successful, and was replaced by the Land Transfer Act, 1875. Under the Act of 1875 registration continued to be optional, and the new system set up by the act did not have the effect of increasing the use of registration. The Land Transfer Act, 1897, amended the Act of 1875 in important particulars and also contained provisions under which—subject to the exercise of a power of veto given to the county council—registration on sale might, by Order in Council, be made compulsory as respects any county or part of a county. Under these provisions Orders in Council were made rendering registration compulsory in the city and county of London; but elsewhere registration under the Land Transfer Acts remained optional. These acts, together with amendments contained in the Law of Property Acts 1922 and 1924, are now consolidated by the Land Registration Act 1925 (15 Geo. V. chap. 21) which came into operation on 1st January 1926. That act—in addition to making certain changes designed to bring the system of registration of title into line with the changes effected in the law of property by the Law of Property Act, 1925, the Land Charges Act 1925, and the other property statutes which came into operation on the same date—makes a noteworthy change with respect to the extension in future of the area of compulsory registration; for it is provided that, after the expiry of ten years from the commencement of the act, i.e. on and after 1st January 1936, the system of compulsory registration may be established in any county or part of a county by Order in Council, without any resolution by the county council in favour of such extension and notwithstanding any resolution of the county council that

such extension is not desirable. After 1st January 1926 the only interests in land in respect of which a proprietor can be registered are those which under the Law of Property Act 1925 are recognised by law as 'legal estates.' All other interests in registered land take effect as equitable interests. A legal estate cannot be held by an infant. Registration confers on the registered proprietor statutory powers to deal with the land (subject to entries on the register) in any way permissible by the general law. Thus he can not only transfer and charge the land but he can also lease it and create easements and restrictive covenants. A transfer of the land, or of any part of the land, comprised in the title of a registered proprietor, is completed by the registrar entering on the register the transferee as proprietor of the land transferred. As regards deeds affecting interests in lands—a system of registering such deeds had long been in use in Middlesex and Yorkshire. By the Land Charges Registration and Searches Act, 1888, amended by the Land Charges Act, 1900, a general system for the registration of deeds of this description was brought into operation. This system is now regulated by the Land Charges Act, 1925 (15 Geo. V. chap. 22), which provides that there shall continue to be kept at the office of Land Registry (1) a register of pending actions relating to land; (2) a register of annuities or rent charges, granted otherwise than by marriage settlement or will, for a life or lives, if created prior to 1st January 1926—these charges, after that date, to be entered in the register of land charges; (3) a register of writs and orders affecting land; (4) a register of deeds of arrangement affecting land; (5) a register of land charges. The act has greatly extended the classes of 'land charges,' which must be registered in the register of land charges to render them binding on a purchaser.

Registration of Writs in Scotland.—In Scotland there exists, and has long existed, a very complete system of registration of legal writs. This system has three main purposes or applications, viz. publication, execution, and preservation. Registration for publication has been developed and applied chiefly in relation to writs dealing with proprietary and subsidiary rights in land. The existing system of land registration owes its origin to the statute 1617 chap. 16. That statute established a general register at Edinburgh and particular or local registers throughout the country, and directed that all sasines and all writs relating to the constitution, transfer and discharge of redeemable rights in land, should be registered therein within sixty days of their dates, writs relating to burghage subjects being excepted. When, by statutes passed about the middle of the 19th century, the instrument of sasine and the whole ceremony of sasine were dispensed with, the direct recording of the deed of conveyance, with warrant of registration thereon, was recognised as a sufficient completion of the disponee's real right. In place of the deed itself a notarial instrument, describing the nature of the deed and setting forth its operative parts, may be recorded. Registration may now take place at any time during the life of the person on whose behalf the writ is presented for registration. The Land Registers Act, 1868, abolished the particular feudal registers, made the general register the only competent register for all writs relating to lands not held burghage, and provided that the general register should be divided into a series of separate divisions, and that writs be entered in the division applicable to that county or registration district in which the lands affected by the writs are situated. Each royal burgh, with a few exceptions, had its register in which conveyances of land held burghage were recorded; and, notwith-

standing the abolition by the Conveyancing Act 1876 of the distinction between feudal and burgage tenure, writs of lands held burgage immediately before the commencement of that act still fall to be recorded in the burgh registers. Other registers for the publication of writs affecting land are the register of entails and the register of inhibitions and adjudications. Registration for execution, i.e. for the enforcement of an obligation, is of very ancient origin. The process, which in early times was in its essential features simply an abbreviated action in court, now retains scarcely any distinctive marks of its judicial origin. In a bond or other deed by which an obligation is constituted a short statutory clause is inserted consenting to registration for preservation and execution—a clause which imports consent to the writ being registered in the books of a competent court and to a summary warrant for execution being issued as if a judicial decree for its enforcement were pronounced. By special statute the privileges of registration in order to summary enforcement are extended to bills and promissory notes, the acceptance and subscription of which implies a consent to registration for execution. Registration for preservation provides against the loss of important writs, and has the convenience of enabling parties to obtain at any time authentic copies of the registered writ, in the form of extracts from the register. The records now available for registering deeds for preservation or execution are these: (1) The Register of the Great Seal; (2) the Books of Council and Session, for all deeds and probative writs; (3) the books of any Sheriff Court for all deeds and probative writs; (4) the books of royal burghs for instruments of protest on bills or notes; (5) the General Register of Sasines, for deeds that are recorded for preservation or for preservation and execution as well as for publication.

Registration of Electors.—It is a condition precedent to the right of any person to vote in a parliamentary election or in a local government election that his or her name should be upon the register of electors for the time being in force. The Representation of the People Act, 1918 (8 Geo. V. chap. 64), introduced new qualifications for the franchise; extended the franchise to women, subject to certain limitations; shortened the period of qualification from one year to six months; and established a system of official registration of electors. The register, which contains the names of those who are entitled to vote as parliamentary electors and of those who are entitled to vote as local government electors, is compiled by the registration officer for each registration area. In England each parliamentary county or borough is a registration area; and the registration officer is, in counties, the clerk of the county council, and, in boroughs, the town-clerk. In Scotland each burgh which was entitled under the law in force at the date of the act to appoint an assessor for the purpose of parliamentary registration, and—exclusive of such burghs—each county, or each part of a county which lies within a separate parliamentary division, is a registration area; and the assessor of the burgh or county under the Valuation Acts, or one of such assessors appointed for the purpose by the town or county council, is the registration officer. Two registers of electors are prepared in every year—one, the Spring Register, for the qualifying period of six months ending 15th December, and the other, the Autumn Register, for the qualifying period of six months ending 15th June. The registration officer is charged with the duty of ascertaining what persons in the area for which he is registration officer are entitled to be registered as parliamentary and as local government electors by reason of their having fulfilled

the conditions of the franchise during the qualifying period, and of placing the names of these persons on the register. For this purpose instructions may be issued to the overseers of parishes who make the necessary inquiries. The registration officer may require any householder or any person owning or occupying land or premises within his area, or the agent or factor of such person, to give, in the prescribed form, the information required for the purpose; and the failure of the householder, owner, occupier, or agent to give the required information renders him liable to a penalty of £20. The registration officer, having prepared lists for each registration unit within his area of all persons appearing to be entitled to be registered as electors, makes copies of these lists available for inspection by the public in his office and in the chief post-office or other convenient place in the registration unit, and at the same publishes a notice specifying the mode in which, and the time within which, claims and objections are to be made. He then, after considering claims and objections, and making the necessary corrections in the lists, forms these lists into a register, with a separate index letter and a separate series of numbers for each polling district. The register is made up in separate parts for each registration unit in the registration area, and is framed so as to distinguish the names of those who are entitled to vote as parliamentary and as local government electors. A copy of the register is open to inspection at the registration officer's office, and copies of the part of the register relating to any registration unit are kept for inspection in that unit at a convenient place. Anyone who is entitled to make and has made a claim or objection can appeal to the county court—in Scotland, the sheriff court—from the decision of the registration officer, whether such decision be on a question of fact or on a point of law. A person desiring to appeal must give notice of appeal, in the prescribed form, to the registration officer and to the opposite party, if any, within five days after the decision is given. The notice of appeal must specify the grounds of the appeal. On any point of law, but only on a point of law, an appeal lies, in England, from the decision of the county court to the Court of Appeal, and, in Scotland, from the decision of the sheriff court to a court of three judges of the Court of Session. As regards university constituencies, the governing body of every university forming, or forming part of, a university constituency must cause a register to be kept, in such form and made up to such dates as it may direct, of persons entitled to vote in respect of a qualification at that university, and must make the register available for the purpose of university elections for the constituency. This register is open to inspection by any person who makes application.

Registration of Births, Deaths, and Marriages.—In England a complete system of civil registration of births, deaths, and marriages was established by acts passed in 1836. The system instituted by these acts has been considerably altered and amended by subsequent registration acts. Before the establishment of the system of civil registration there had been long in operation a system of ecclesiastical registration of marriages, baptisms, and burials solemnised according to the rites of the Church of England, it being the duty of the officiating minister to keep such a register (see REGISTERS, PARISH). There were also in existence many non-parochial registers. The whole existing system is under the supervision of the Registrar-General. Every poor-law union or parish is divided into registration districts, each of which is in charge of a locally-resident registrar. The registrars of each union are supervised by a superintendent registrar. Quarterly returns of certified copies of

the entries in the local register books are sent to the superintendent registrar of the district, by whom they, if found correct, are transmitted to the general register office. There they are preserved, and may be inspected or excerpted on payment of a small fee. Entries in the registers of births, deaths, and marriages and certified copies thereof are admissible to prove facts therein stated.

As regards births—it is, in the case of every child born alive, the duty of the father and mother or, in their default, certain other specified persons to give notice of such birth to the district registrar within forty-two days after the day of the birth, and, in his presence, to sign the register. After a period of three months from the birth of the child registration may take place on a solemn declaration before the superintendent registrar being made by one of the persons on whom is imposed the duty of giving the information as to the birth. After the expiry of twelve months from the time of the birth, registration can be effected only with the written authority of the Registrar-General. The particulars to be registered are the date and place of the birth; name and sex of child; name and occupation of the father; and the name and maiden surname of the mother. The signature, description, and residence of the informant are also entered. The date of registration is stated, and the entry is signed by the registrar.

As to deaths—it is the duty of the nearest relatives of the deceased, present at the death, or in attendance during his last illness, and, in default of such relatives, of certain other specified persons to give to the registrar the required information within the five days next following the day of death. When a written notice, with a medical certificate of the cause of death, is sent to the registrar, the time of registration is extended to fourteen days next after the death. If a death is not duly registered the registrar may, after fourteen days, and within twelve months from the date of death, require, by written notice, any of the persons whose duty it is to register the death to attend at his office, and furnish him with the statutory particulars. The particulars to be registered are the date, the name, sex, age, and rank or occupation of the deceased; and the cause of death. The signature, description, and residence of the informant are also required. The entry is signed by the registrar.

As to marriages—all persons authorised to solemnise marriages (see MARRIAGE) are required to keep a register of marriages solemnised by them, and to transmit copies thereof quarterly to the superintendent registrar of their district, who sends certified copies to the Registrar-General's office. The particulars required to be registered are the date, name, age, condition, rank or occupation, and residence of each of the parties, and name, rank or occupation of the father of each of the parties.

In Scotland a general system of registering births, deaths, and marriages was introduced by the Registration Act, 1854. Prior to that act the only records were the old parochial registers, which were ecclesiastical and very incomplete. The existing Scottish system is, in its main outlines, similar to that obtaining in England. Information of a birth, with the required particulars, is to be given to the registrar of the parish or district within twenty-one days of the birth. If a period of more than three months elapse before the information is given, the parents or guardians make a declaration before the sheriff, who may then authorise the registrar to register the birth. Information of a death is to be given within eight days of the event. In the case of regular marriages the

necessary information is inserted in a statutory schedule, which must be produced to the officiating minister. The schedule, after being filled in, is signed by the contracting parties, the minister, and not fewer than two witnesses, male or female, present at the ceremony. It must then be sent, within three days, to the registrar of the parish in which the marriage was solemnised. Provision is made, when the parties desire it, for the attendance of the registrar at the ceremony. The particulars on the statutory schedule are entered by the registrar in duplicate registers. All such schedules, along with one of the duplicate registers, are in due course transmitted to the Registrar-General for preservation in the General Registry Office. (As to registration of irregular marriages—see MARRIAGE.) The office of Registrar-General was formerly held by the Deputy Clerk Register, but an act which came into operation on 23d December 1920 provided for the appointment of a Registrar-General of Births, Deaths, and Marriages in Scotland.

In England and Scotland there are various other public registers dealing with special matters.—See BILL OF SALE, COMPANY, FRIENDLY SOCIETIES, COPYRIGHT, PATENTS, TRADE MARKS, SHIP-BUILDING, WILLS. There are also registers in relation to professions, e.g. the medical register, on which are placed the names of persons possessing one or more of specified qualifications; the dentists' register; the register of money-lenders. The Registration of Business Names Act, 1916, requires registration in the manner directed in the act of, *inter alia*: (a) every firm having a place of business in the United Kingdom, and carrying on business under a business name which does not consist of the true surnames of all partners who are individuals, and the corporate names of all partners who are corporations; and (b) every individual having a place of business in the United Kingdom, and carrying on business under a business name which does not consist of his true surname.

Regium Donum (Lat. 'royal gift'), an annual grant of public money formerly received by Nonconformist ministers in England, Scotland, and Ireland. It began in 1672, when Charles II. gave £600 of secret-service money to be distributed annually among the Presbyterian clergy in Ireland, on hearing that they had suffered on his account. The grant was discontinued in the latter part of his reign and in James II.'s, but was renewed in Ireland by William III. in 1690, who increased it to £1200 a year. It was further augmented in 1723 by George I., in consequence of the Presbyterians having supported the House of Brunswick, and reached £45,000 before it was withdrawn, when the Irish Episcopal Church was disendowed. Compensation was made of life interests. The Regium Donum in England was enjoyed by Presbyterians, Independents, and Baptists, from 1723 till 1857. The Scottish Episcopals also enjoyed for a time a small part.

Regnard, JEAN FRANÇOIS, French comic dramatist, was born at Paris in 1655. A rich shop-keeper's son, he found himself at twenty master of a considerable fortune, and at once set out on his travels. In Italy he gave himself up to gambling, but, strange to say, increased rather than diminished his means. In his autobiographical romance, *La Provençale*, we read, but somewhat dubiously, of the passion of himself as Zelmis for a young Provençal wife (Elvire), his voyaging back to France with her and her husband, their capture and sale as slaves by Algerian pirates, how he made himself pleasing to his master by skill in cookery, was carried by him to Constantinople, and, at the end

of his two years' captivity and many strange adventures, was ransomed, together with the lady, for 12,000 crowns. Her he was next about to marry when the husband reappeared, and sent the lover off again on aimless wanderings through Holland, Denmark, and Sweden, to Lapland, and back by Poland, Turkey, Hungary, and Germany. From his return to Paris (1683) he gave himself to letters, and found his true vocation in the success of *Le Divorce* at the Théâtre Italien in 1688. Eight years later his fine comedy, *Le Joueur*, achieved success at the Théâtre Français. Its successors were *Le Distrain* (1697), *Le Retour Imprévu* (1700), *Les Folies Amoureuses* (1704), *Les Ménéchmes* (1705), and his masterpiece, *Le Légataire Universel* (1708). He died before his time, and so suddenly as to originate various contradictory reports, 4th September 1709. Regnard was an indifferent poet, but he was a master of dramatic situation and of comic dialogue, if not of verisimilitude or reality. To this day the reader endorses Boileau's judgment, expressed once when someone charged Regnard with mediocrity - 'Il n'est pas médiocrement gai.' 'Qui ne se plaît point à Regnard,' said Voltaire, 'n'est pas digne d'admirer Molière.'

There are editions by Didot (1820), Michiels (1854), and Fournier (1875). See the study by J. Guyot (Paris, 1907), and *Bibliographie* by Marchéville (1877).

Regnault, ALEXANDRE GEORGES HENRI, painter, was born in Paris, 30th October 1843, the son of Henri Victor Regnault (q.v.). His aptitude for drawing manifested itself very early, and he was continually sketching the animals in the Jardin des Plantes. After an excellent career in the Lycée Napoléon, he left school in 1859, and studied art under Lamoignon and Cabanel; and, after two unsuccessful attempts, gained the *prix de Rome* in 1866. Reaching Rome early in the following year, he executed there a remarkable portrait of Madame Duparc, and his historical sketch of 'Automedon breaking the Horses of Achilles,' and drew on wood illustrations for Way's *Rome*. He next passed to Spain with his friend Charin; and here, as afterwards in Tangier, he found subjects of that wildly picturesque character which best suited his genius. In 1869 he painted his powerful equestrian portrait of General Prim, now in the Louvre, and his 'Judith,' and in 1870 contributed his 'Salomé' to the Salon. In 1870 was also painted, at Tangier, his terrible picture, 'The Execution without Judgment under the Moorish Kings of Granada'—a work now in the Louvre. In the same year he returned to Paris on the outbreak of the Franco-Prussian war; and though, as a *prix de Rome*, he was exempt from military service, he volunteered as a private soldier, and on the 19th January 1871 was slain on the field of Buzenval, in his twenty-eighth year. As an artist he had by no means fully expressed himself; but he had produced much that was marked by great energy and power, that caught in a peculiarly vivid way the splendid and barbaric life of the East—a life, in the words of the painter himself, 'at once rich and great, terrible and voluptuous.' A monument to Regnault, sculptured by Henri Chapu, has been erected in the Ecole des Beaux Arts, Paris.

See the *Lives*, in French, by Cazalis (1872) and Marx (1887), and his *Correspondance*, ed. by Duparc (1873).

Regnault, HENRI VICTOR, chemist and physicist, was born at Aix-la-Chapelle, 21st July 1810. A shopman in a Paris bazaar, he made such good use of his scanty leisure as to qualify himself for admission (in 1830) to the Ecole Polytechnique, and, after the two years' course, entered the Ecole des Mines. He became a professor in Lyons,

whence, in 1840, he was recalled to Paris as a member of the Academy of Sciences, in consequence of some important discoveries in organic chemistry. Having filled chairs in the Ecole Polytechnique and the Collège de France, he became in 1854 director of the imperial porcelain-manufactory of Sèvres. He devoted himself to the determination of important physical data, such as the laws of expansion of gases, the measurement of temperature, latent and specific heats, and especially the numerical data bearing on the working of steam-engines, for which the Royal Society of London awarded him its Rumford medal. He also received the Copley medal (1869) of the Society, and was one of its foreign members. In addition to numerous papers in the *Annales de Chimie*, &c., he published a *Cours Élémentaire de Chimie* (4 vols. 14th ed. 1871). He died 20th January 1878. See the *Éloge Historique* by Dumas (1881).

Régnier, HENRI DE, French poet and novelist, was born at Honfleur in 1864, and was educated at the Collège Stanislas, Paris. His prose works include *La Canne de Jaspe* (1897), *La Double Maîtresse* (1900), *Le Roman d'un Jeune Homme Sage* (1903), *Le Passé Vivant* (1905), *L'Amphibène* (1912), *Romaine Mirmault* (1914), *L'Illusion Héroïque de Tito Bassi* (1916), and *La Pêcheresse* (1920), while among his collections of verse are *Poèmes Anciens et Romanesques* (1890), *Les Jeux Rustiques et Dirins* (1897), *Les Médailles d'Argyle* (1900), *La Cité des Eaux* (1902), *Le Miroir des Heures* (1911), and *Vestigia Flammæ* (1921). Régnier married a daughter of de Hérédia, and in 1911 became a member of the French Academy. He has continued the symbolism of Mallarmé (whom he knew personally), writing poetry which by reason of its subject and the musical versification suggests a picture—the playing of fountains, a Grecian frieze, a palace set with precious stones—which, in turn, gives rise to the particular mood or atmosphere that the poet desires. His poems, whether in the form of sonnets or 'vers libres' or 'odelettes' (short lyrics, which he himself created), are all tinged with a gentle melancholy. Some of his novels dealing with contemporary life are, perhaps, not so successful. See the studies by de Gourmont (1908) and Berton (1910); also A. Lowell, *Six French Poets* (1915).

Régnier, MATHURIN, a great French satirist, was born at Chartres, 21st December 1573. His father was a well-to-do citizen; his maternal uncle was the Abbé Desportes the poet. The boy was tanned at vine, but grew up dissipated and idle. In early youth he seems to have visited Italy in the suite of the Cardinal de Joyeuse, and is supposed later to have transferred his services to Philippe de Bethune, who went as ambassador to Rome in 1601. He obtained a canonry at Chartres, and enjoyed the favour of Henry IV. and his court. But his follies sapped his health, and he died an untimely death, 13th October 1613. His first collection of satires had appeared in 1608. Régnier's whole work together scarce exceeds 7000 lines—sixteen satires, three epistles, five elegies, and some odes, songs, epigrams, and miscellaneous pieces—yet it is enough to place him high in the order of merit among the poets of France. He is greatest in his satires, written in the usual Alexandrine couplet, and admirably polished, yet vigorous and original. They touch social and moral questions only, and consequently are not of merely ephemeral interest, as political satires most often are; and, what is rare in French satire, they mostly escape the fault of handling abstract types instead of actual concrete embodiments of the type. Breadth, force, and reality characterise them all, but these merits

together reach their highest point in the thirteenth, *Macette*, a satire on a hypocritical old woman who corrupts the hearts of the young around her by her cynical views of life. Régnier imitated indeed the satire of Juvenal and Horace, yet he did not copy it, and he threw his own heat into the form he borrowed. He was the last of the great poets of the 16th century: after him was to follow a period of barrenness, alike from the poverty of nature and the sterilising influences of the traditions of Malherbe and his school. It was against the attacks of Malherbe that Régnier championed Ronsard, and later he himself was defended by Boileau.

Editions are by Brossette (1729), Lenglet Dufresnoy (1733), Prosper Poitevin (1860), M. de Barthélemy (1862), and E. Courbet (1875). See Cherrier's *Bibliographie de Régnier* (1889), and Gosse's *French Profiles* (1905).

Regrating. See ENGROSSING.

Regular Canons. See CANON.

Regulars. See CLERGY.

Regulus, a term in Metallurgy, which is now used in a generic sense for metals in different stages of purity, but still retaining, to a greater or less extent, the impurities they contained in the state of ore. When, for example, the ore known as the sulphide of copper is smelted, the product of the different furnaces through which it passes is called regulus until it is nearly pure copper. The name, which signifies 'little king,' was first given by the alchemists to the metal antimony, on account of its power to render gold brittle.

Regulus. See GOLDEN-CRESTED WREN.

Regulus, MARCUS ATILIUS, a favourite hero with the Roman writers, was consul for the first time in 267 B.C., and for his military successes obtained the honour of a triumph. Chosen consul a second time (256), he was sent along with his colleague Manlius at the head of a navy of 330 ships against the Carthaginians, and encountering the enemy's fleet off Heraclea Minor he totally defeated it. The Romans then landed near Clypea, where for some time Regulus was victorious in every encounter, but at last (255) suffered a total defeat and was taken prisoner. He remained in captivity for five years, but when fresh reverses induced the Carthaginians to solicit peace Regulus was released on parole and sent to Rome in company with the Punic envoys. It is related by the Roman poets and historians, as an instance and a model of the most supreme heroism, how Regulus at first refused to enter Rome since he was no longer a citizen: how, after this conscientious scruple was overcome, he declined to give his opinion in the Senate till that illustrious body laid upon him its commands to do so; how he then earnestly dissuaded them from agreeing to any of the Carthaginian proposals, even to an exchange of prisoners; and how, after he had succeeded by his earnest appeals in obtaining the rejection of the Carthaginian offers, he resisted all persuasions to break his parole, though conscious of the fate that awaited him, and, refusing even to see his family, returned with the ambassadors to Carthage, where the rulers, maddened by the failure of their schemes through his instrumentality, put him to death by the most horrible tortures. The common story is that he was placed in a cask or chest stuff full of nails, also that, with his eyelids cut off, he was exposed to the glare of the African sun. Unfortunately this noble tale of heroic patriotism and unflinching fortitude is unhistorical, or at least unsupported by any good authority.

Regulus, or RULE, ST, according to legend, a monk of Constantinople or bishop of Patras who in 347 A.D. came to Muckross or Kilmot (after-

wards St Andrews), bringing relics of St Andrew to Scotland from the East. The adoption of St Andrew as the national patron saint appears to belong to the first half of the 8th century; and for the possible identification of St Regulus with an Irish St Kiagail of the 6th century, see Skene's *Celtic Scotland* (vol. ii. 1877).

Regur, the rich, black cotton soil of India. It is the result of the long-continued growth and decay of vegetation—the organic residue being commingled with the disintegrated and decomposed débris of the subjacent rocks.

Reichenbach, a manufacturing town of Saxony, 11 miles SW. of Zwickau, produces woollen fabrics—merinoes, flannel, shawls—and has dyeing and calico-printing works; pop. 30,000.

Reichenbach, a cotton and woollen manufacturing town of Prussia, in Lower Silesia, 32 miles SW. of Breslau; pop. 15,000.

Reichenbach, HEINRICH GOTTLIEB LUDWIG (1793-1879), botanist and zoologist, was from 1820 a professor at Dresden.—His son, HEINRICH GUSTAV (1824-89), was also a botanist, a professor at Hamburg from 1862. He was famous in connection with orchids.

Reichenbach, KARL, BARON VON, naturalist and technologist, was born at Stuttgart, 12th February 1788, and educated at Tübingen. After a short political imprisonment at the instigation of the French authorities, he studied the industrial arts, and in 1821, in connection with the Count of Salm, he started a number of factories of different kinds at Blansko in Moravia, which he managed with great success, retiring with a fortune. He devoted much study to the compound products of the distillation of organic substances, and he succeeded in bringing to light a number of compounds of carbon and hydrogen not previously known; among these were creasote (1833) and paraffin. Studying with enthusiasm the subject of 'animal magnetism,' he discovered, as he thought, a new force in nature, which he called Od (q.v.), and conceived to be intermediate between electricity, magnetism, heat, and light, and recognisable only by the nerves of sensitive persons. His chief works are *Geologische Mittheilungen aus Mahren* (1834), *Untersuchungen über die Dynamide des Magnetismus* (1847-49), several works on 'odde force' (1852-58), *Aphorismen* (1866), *Die Odische Loke* (1867). His *Letters on Od* (1926) and some other works have been translated. He died at Leipzig, 19th January 1869. See biographical works by Schrötter (1869) and Fechner (1876).

Reichenberg (Czech, *Liberec*), the chief seat of the cloth manufacture in North Bohemia, stands on the Neisse, 86 miles by rail NE. of Prague. Apart from the principal industry, machinery and leather are manufactured. The cloth industry was established in the 16th century. In 1920 an annual fair on the Leipzig model was started, to represent Czechoslovak industry. There is an important industrial school. Pop. 35,000.

Reichenhall, an Alpine spa in the extreme south-east of Bavaria, 10 miles SW. of Salzburg. It was almost wholly consumed by fire in 1834, and handsomely rebuilt. It is the chief centre of the Bavarian salt-works. The salt-springs are fifteen in number, two yielding 25 per cent. of salt.

Reichstadt, DUKE OF. See NAPOLEON II.

Reichstag, **Reichsrat**. See GERMANY and AUSTRIA.

Reid, CAPTAIN MAYNE, writer of boys' stories (originally Thomas Mayne Reid), was born at Ballyroney, County Down, in 1818, the son of a

Scoto-Irish Presbyterian minister, and studied four years for the ministry, but, disliking his intended profession, he at twenty emigrated to America, where he led a roving and adventurous life, in turn storekeeper, negro-overseer, schoolmaster, actor, and journalist. He served in the United States army during the Mexican war of 1847, and distinguished himself especially in the storm of Chapultepec. The Hungarian struggle, in which he had meant to take part, was at an end before he reached Europe, whereupon he settled down to a literary life, first at London, next in Buckinghamshire. He died 22d October 1883. His vigorous style and the profusion of hairbreadth 'scapes he provided delighted his breathless readers, who did not stop to notice the truthfulness of his scenery and the occasional excellence of the narrative style. Among his best books were the *Boy Hunters* (1853), the *Bush Boys* (1856), and the *Boy Tar* (1859), the *Scalp Hunters* (1851), the *Life Rangers* (1850), the *War Trail* (1857), and the *Headless Horseman* (1866). See his *Life and Adventures* by his widow (1900; expanded from an 1890 memoir).

Reid, SIR GEORGE (1841-1913), was born at Aberdeen. Trained as a lithographer, he studied art in the Trustees' Academy, Edinburgh, under Mollinger at Utrecht, under Yvon in Paris, and with Israels at the Hague. He was elected A.R.S.A. in 1870, and R.S.A. in 1877, and from 1891, when he was knighted, till 1902 (when he resigned) was P.R.S.A. He is most widely known by his portraits, which are distinguished by unflinching verisimilitude, vigorous handling, and thorough modelling. His half- and full-lengths are remarkable for their individuality of attitude, for the insight with which, in each case, the characteristics of the sitter are expressed by the entire figure, as well as by the face. Among his more important portraits are 'Lord President Inglis,' in the Scottish Parliament House; 'H. Wellwood Maxwell of Munches;' and 'John Mackenzie.' He also produced many rich, freely painted flower-pieces, as well as landscape work of a delicate and quiet charm; and his book illustrations prove him one of the most accomplished draughtsmen of his time.

Reid, THOMAS, head of the Scottish school of Philosophy, was born on the 26th April 1710, at Strachan, a country parish in Kincardineshire, where his father was minister. His mother belonged to the well-known family of the Gregorys (q.v.). Reid began his education at the parish school of Kincardine, and at the age of twelve he became a student of Marischal College in Aberdeen. He took his degree of M.A. in 1726, and continued to reside in Aberdeen as college librarian, his chief studies being mathematics and the natural philosophy of Newton. In 1736 he left Aberdeen, and went to England, where he was introduced to the most distinguished men in Oxford, Cambridge, and London. In the following year he was presented by the senatus of King's College to the parish church of New Machar in Aberdeenshire. The parishioners were bitterly opposed to his appointment, but his conduct and manner gradually won them over. It is said that, from distrust of his powers, instead of composing for the pulpit himself, he preached the sermons of Tillotson and other English divines. In 1739 Hume's *Treatise on Human Nature* appeared, the perusal of which gave the impulse that determined Reid's future philosophical career. He had fully adopted the idealism of Berkeley, but was now revolted by the conclusions drawn from it by Hume, and in consequence was led to seek a new foundation for the common notions as to a material world. In 1748 he contributed to the Royal Society of London a short essay on *Quantity*. In 1752 he was appointed one of the

professors of Philosophy in King's College, Aberdeen, the senatus being the patrons of the chair. Here he followed the established course of teaching in three successive years to the same students mathematics, natural philosophy, and moral philosophy. He was the founder of a Literary Society in Aberdeen, which enrolled among its members Campbell, Beattie, and other men of ability; to this society he submitted his first draft of the *Inquiry into the Human Mind*. In 1763 he was chosen to succeed Adam Smith as professor of Moral Philosophy in the university of Glasgow. In 1764 he published his *Inquiry*. His thirst for general science never left him; at the age of fifty-five he attended Black's lectures on Heat. He continued in the duties of his chair till 1780, when he retired to devote his remaining strength to the publication of his works on the mind. In 1785 the *Philosophy of the Intellectual Powers* appeared, and in 1788 the *Active Powers*—together forming a systematic work on the science of the human mind. In 1774 he had contributed his account of Aristotle's logic to Lord Kames's *Sketches*. The publication of the *Active Powers* was the close of his career as an author, although to the end of his life he kept up his bodily and mental vigour and his interest in science. He was taken ill suddenly in the autumn of 1796, and died on the 7th October.

Like Kant, Reid was roused to metaphysical research by Hume, and became the chief of a school whose aim was to deliver philosophy from scepticism, and to do so by resting finally on principles of intuitive or *a priori* origin. The Scottish philosophy, dominant till Sir W. Hamilton's time in Scotland, and influential in France (see ROYER-COLLARD), found a zealous defender in McCosh (q.v.).

See COMMON SENSE, SCOTTISH PHILOSOPHY; the *Life* by Dugald Stewart prefixed to Reid's works (4 vols. 1803); the edition by Sir W. Hamilton (1853); McCosh's *Scottish Philosophy*; and Campbell Fraser's monograph (1898).

Reigate, a town of Surrey, pleasantly situated at the southern base of the North Downs, 21 miles S. of London. Of the castle of the Earls of Warrene little remains save a grassy mound, with large vaults or caverns beneath it. The church, with a nave dating back to 1180 and Transition Norman piers, is mainly Perpendicular, and contains the grave of Lord Howard of Effingham, and a library (1701) with some curious MSS. and many of Evelyn's books. Other buildings are Reigate Priory, the grammar-school (1675), the old town-hall (1708), and the municipal buildings (1901). Foxe the martyrologist is claimed for a resident; and Archbishop Usher died here. The town has spacious public parks, commons, and open spaces. Till 1832 Reigate returned two members to parliament, and then one till 1867. It was incorporated as a municipal borough in 1863. Redhill, two miles east, is within the borough and is the centre of business. Pop (1851) 4927; (1881) 18,662; (1921) 28,914.

Reign of Terror. See DANTON, ROBESPIERRE.

Reikiavik. See REYKIAVÍK.

Reimar's, HERMANN SAMUEL (1694-1768), was born at Hamburg. He studied at Jena and Wittenberg, travelled in Holland and England, and was rector of the school at Wismar, and later professor of Oriental Languages at the gymnasium of Hamburg. He is the author of the so-called 'Wolfenbüttelsche Fragmente,' published by Lessing in 1774-78 (further portions by others in 1787 and 1850-52). These 'Fragments,' up to that time only known in MS. by a few of Reimar's most intimate friends, produced the profoundest sensation throughout Germany: since in them the author, in the boldest and most trenchant manner,

denied the supernatural origin of Christianity. Another work in the same direction is his *Vornehmste Wahrheiten der natürlichen Religion*; of a miscellaneous character are his *Primæva Wis-mariensis*, *De Vita Fabricii*, and his edition of *Dio Cassius*. See the monograph by D. F. Strauss (1860; 2d ed. 1878; trans. by Voysay, 1879).

Reims, or **RHEIMS**, a city in the French department of Marne, situated on the Vesle (a tributary of the Aisne), 100 miles ENE. of Paris by rail. Strongly fortified with detached forts since the Franco-German war, when it was for a time the German headquarters, it is well built, and from the material employed in building, which is the chalk-stone of the district, and from the prevalence of the older style of domestic architecture, has a picturesque appearance. It is built on the site of *Durocor-torum*, which is mentioned by Cæsar as the capital of the Remi, from which people it subsequently took its present name. Christianity may have found an entrance into Reims at an earlier period, but it was not till about 360 that it became a bishop's see. Under the Frank rule it was a place of much importance, and it acquired a deeply religious interest from its having been the scene in 496 of the baptism of Clovis and his chief officers by the bishop, St Remy (c. 438-533). In the 8th century it became an archbishopric, and from 1179, when Philip Augustus was solemnly crowned there, it became the place for the coronation of the kings of France, who were anointed from a vessel of sacred oil, called the *Sainte Ampoule*, which a dove was said to have carried to St Remy from heaven. Joan of Arc brought the dauphin hither, and the only sovereigns in the long series, down to 1825, not crowned at Reims were Henry IV., Napoleon I., and Louis XVIII. In 1793 the cathedral was attacked by the populace, and the *sainte ampoule* smashed by a *sans-culotte*; and in 1830 the ceremony of coronation at Reims was abolished. Reims was in German hands for a week in September 1914, and thereafter suffered bombardment to the end of the war. The town was wrecked, but the cathedral was not beyond repair. The cathedral is one of the finest extant specimens of Gothic architecture. It was built between 1212 and 1430. Its nave is 466 feet long by 99 in breadth, with a transept of 160 feet, and the height is 144 feet. Its grandest features are the west facade, which is almost unrivalled, with its magnificent doorway (figured at DOOR). The stained glass is remarkable for its beauty; and there are two magnificent tapestries. The Romanesque church of St Remy (mainly 1160-80), with the saint's shrine, is nearly of equal size, but of less architectural pretension. Its nave was ruined in the war. The *hôtel-de-ville* (1627-1880) was reduced to a shell; and little was left of the 'Maison des Musiciens' or of the archbishop's palace. The Lycée (also ruined) represents a former university (1547-1793). Reims is one of the principal entrepôts for the wines of Champagne (q.v.), and the hills which surround the town are planted with vineyards. It is one of the great centres of the woollen manufacture in France, and its manufactures, embracing woollen goods (especially merinoes), mixed fabrics in silk and wool, &c., are called *Articles de Reims*. Pop. (1872) 71,397; (1891) 101,699; (1911) 115,178; (1921) 76,645. See DOUAL.

Reincarnation. Transmigration. Metempsychosis. Man has at all stages of human development endeavoured to picture to himself the future of those whose life on earth has come to an end. Two of the possibilities that have presented themselves are reincarnation, a rebirth in another

body of the same species; and transmigration, the reappearance on earth in a form which differs from the previous one. Side by side with this exists the view, in practice distinguishable only with difficulty, that the soul itself is in the form of an animal. Another form of belief that tends to be confused with the foregoing is that which attributes, usually only to certain persons, successive transformations without intervening death or rebirth; this is in substance allied to the powers of transformation attributed to magicians, just as transmigration proper is, logically, bound up with the creed that living men may, for safety, deposit their souls in some place of safety; but it must not be supposed that the presence of one element implies that of the other.

2. A belief in metempsychosis of one or other kind is found sporadically as an element of popular belief among various tribes in the lower stages of culture, but it is in such cases rarely possible to discover how it originated; the theory was also held, or suggested, by various Greek philosophers without, however, necessarily forming an important element in popular religion. In India and West Africa, on the other hand, there is no doubt as to the hold which it has on people's minds, and in both cases it seems to be the outcome of a seeking for the origins of patent facts—in India for the meaning of the different lot of rich and poor, which in time developed into an ethical creed, the doctrine of the survival of merit and demerit after the death of the individual; while among the Ibo the biological interest is in the foreground, and reincarnation is at the bottom the native explanation of the resemblances between persons of different generations. By somewhat similar reasoning the Australian native at times explains why strangers become fast friends almost at first sight, alleging that the parties must have been comrades in a previous existence, and this theory has also been put forward, doubtless as an original idea, by an Hegelian philosopher of our own time. On the other hand, no clear origin can be assigned to such beliefs as those of the Malagasy, Zulu, &c., to which reference is made below, nor yet to the creed of some totemic peoples that their dead pass into the body of the totem animal.

Certain exceptions, such as the reincarnation creed of the Druids, apart, there seems to be little or no reason for assuming the spread of a belief in metempsychosis outside its own culture area as an explanation of the distribution of the various forms of the creed.

3. Transmigration is the accepted doctrine not only of Hinduism, Jainism, and Buddhism, but is also part of the philosophy of Brahmanism; but in Buddhism it is a popular creed which conflicts with orthodox psychology, and is essentially a misunderstanding of the doctrine of *samsāra*. According to the Upanishads, the 'fine body' and 'moral substratum' (*liṅga-śaraya*) survive even the absorption of the world into Brahman, and condition the resumption of personal existence, till by the acquisition of knowledge (soul = Brahman) unity with Brahman is attained, and the illusion of plurality of existences overcame. Until the 'seed of works' is thus consumed, the cycle of existence must roll on, and even the gods, their tale of merit exhausted, must descend to lower forms of life; conversely, the soul in non-human form (plant or animal), its demerit worked off, rises in the scale of existence. As, among primitive peoples, ethical considerations are not the deciding element when a soul passes from this world, it is not probable that this doctrine of transmigration was at the outset of moral import. It comes in view from an unknown source between the age of the Vedas and that of the Upanishads, and may well have

been developed from a popular belief either of aboriginal tribes or of the Aryan-speaking peoples themselves.

4. In Madagascar there appear to have been many tribes of whom their neighbours asserted that they were transformed at death into animals, or that their souls were in the form of animals; but of only one, the Betsileo, can it be said that they believed this of their own dead; and their creed seems to be without any precise parallel even in Malaysia. Certain serpents, called *fanany*, were said to be formed in a pot beneath the corpse, which is tied to the central pillar of the hut and allowed to putrefy; at first the *fanany* was very small; then it was transported to the family tomb after the human remains had been buried; then, after some months, the python came out and was treated with the utmost respect; the family whose offerings of food it accepted were its kin. This lot was reserved for the nobles; crocodiles and eels were the abode of the souls of others, but the chief who became a *fanany* could accord hospitality to the souls of his descendants. At the death of the soul-animal, the soul passed to the common abode of the dead.

5. The Zulu, like many other peoples, believe that their dead pass, according to their rank, into various kinds of serpents or lizards; but other Bantu-speaking peoples hold that their chiefs, or even the common herd, pass into lions and other animals; some Zambesi tribes say that a man can choose his own soul-animal by swallowing the maggots from the putrefying flesh of his chosen species.

6. How far these beliefs are connected with Totemism (q.v.) is a very open question; but it is certain that some kinds of West African totemism belong to the same complex as the reincarnation creed; for the Siena or Senfofo hold that a man's soul passes into the body of his totem-animal, and conversely the spirit of the dead animal enters a new-born child of the clan. The Efik beliefs as to the 'bush-soul' are also akin to totemism; but in this case it is the soul of the living man that is lodged in the beast; a link with the reincarnation creed is made by the fact that the bush-soul of the reincarnated is the same species of animal as that of the original person.

7. It must, however, be recognised that the beliefs of primitive peoples are even more fluid than our own, and pass one into another with such facility that the true origin and relationships of the various elements are obscured. In another aspect, the reincarnation creed of West Africa is related to the belief in a genius or tutelary spirit; but it is also a theory of human psychology, and the double is confused with the ghost; in yet another aspect the double is a personified promise to return to the other world.

It is therefore clear that no brief synopsis of the facts can be anything but misleading; the account of Ewe beliefs which follows, itself only a sample of West African creeds, makes no pretence of being more than a survey of some features of the reincarnation complex. The Ewe say that man has two souls, one of which goes into the grave, and thence to the land of the dead, which is a duplicate of this world; a man who has been a great king there will die soon after birth here, so that he may return to the scene of his former glories; and an aged man in this world may fall ill because his associates in Amedzowe, impatient at his long absence, are preparing to break down his hut there; his relatives in Amedzowe send him to this world. Side by side with this belief is another which says that Mawu, the supreme god, decides the lot of a soul that is going from Amedzowe, and also fixes the length of his life. A third account says that a man has one

or more *kla* or *aklama* (tutelary geniuses), which are often confused with the *luwo* (soul); Mawu sends the *kla* into a man, and it determines his character; if a man does not fulfil his obligations, e.g. food tabus, his *kla* will not protect him. When a man dies, the figurines which represent the *kla* are broken, and it becomes a ghost which goes to a place under the earth; both *luwo* (soul) and *aklama* are termed *noli* after a man's death.

The deep-rooted confusion disclosed by this summary is paralleled among the Edo of Benin, though the aspect of the creed differs widely; among them the genius is double, and some say that the one in *elim* (heaven) comes to earth when the one on earth leaves the corpse of a dead man.

8. There are certain tribes of Central Australia which hold a reincarnation creed according to some authors; but the facts as to the Arunta beliefs are not clear; the Chingali, however, declare that ancestors are repeatedly reincarnated, with change of sex each time.

Some authors have traced the origin of totemism in Indonesia and Oceania to the belief that the soul at death passes into an animal which thus becomes sacrosanct; the same belief is found sporadically in New Guinea, North and South America; the exact significance of the facts is, however, not quite clear.

9. Among the ancient inhabitants of Europe belief in reincarnation was an important element in the creed of the Druids; but it is not clear how far it was confined to them, or common to the whole people, and taught especially by the Druids. They seem to have held that there was a life in another world before reincarnation in this.

10. Among the Greeks belief in reincarnation was a feature of the worship of Dionysus and the Orphic cults in the 6th century B.C., but it was taught and known at an earlier date; for Herodotus declares, without good grounds, that it came from Egypt. References to the 'Weary Wheel' suggest that Oriental influences played some part; but the Asiatic 'Wheel of Life' may well have no causal connection with the Wheel of Fortune; at a period when pictorial representations were hardly likely, even if in existence, to pass from east to west, independent origin is the more probable. The name of Pythagoras is specially associated with the doctrine of reincarnation. He taught that all living things are akin; hence man should abstain from a flesh diet. Other names associated with the doctrine are Empedocles, Plato, and Plotinus, but it is not clear how far these teachers made any impression on the mass of the people.

11. There is nothing to show that metempsychosis played any part in Roman beliefs; such mentions of it as are found are clearly derived from Greek sources. Of uncertain origin and very minor importance is the doctrine of metempsychosis among the Jews, with whom it forms part of a system of esoteric mysticism, first recorded in mediæval times. There is some evidence for the existence of a belief in metempsychosis among early Teutonic peoples; but, as among the Celts, the evidence is mainly literary, and does not necessarily imply a living belief contemporary with the record.

12. Somewhat akin to the doctrine of reincarnation is a theory propounded in modern times to explain the nature of personality. It has been suggested that the real Self is something far more extensive than personality as we know it; the Self is, as it were, confined in a chamber, and manifests itself in the world only dimly and partially, through, as it might be, an aperture small in proportion to the whole; in successive existences, different facets of the Self come in contact with existence.

The more important sources are collected by the writers in Hastings, *E.R.E.*, s.v. Transmigration. See also Rivers, *Melanesian Society*, ii. 361-372; De la Vallée Poussin, *The Way of Nirvana*; B. H. Streeter, *Immortality*.

Reindeer. or CARIBOU (*Rangifer tarandus*), a species of deer, the only representative of the genus. It is a native of the northern parts of Europe, Asia, and America, and was introduced into Iceland in 1770. In Caithness it existed till the middle of the 13th century (Harting's *Extinct British Animals*, 1880). It is by far the most valuable of the deer, for not only are the flesh and skin of much use, but the animal has long been domesticated in Scandinavia, especially among the Laplanders. The wild reindeer of Lapland is almost equal in size to the stag, but there are great differences of size in different districts, the largest size being generally attained in the polar regions. The domesticated animal is never so large as the wild one; but that of Siberia is, like the wild one, much larger than that of Lapland. The reindeer is strong, somewhat heavily built, but yet very swift. The hair is longer in winter, and is gray or brownish in colour. The legs are short and thick, and the broad main hoofs spread out as the animal speeds over the snow. Besides the main hoofs, there are two accessory lateral hoofs. The head is carried horizontally, not erect as in other deer. The muffle of the nose is hairy. The antlers are large and are unique in being possessed by both sexes. Moreover, they begin to appear at an early stage in life, within a few weeks after birth, and at the same time in both sexes, whereas in the other deer, in which only the males have antlers, they do not appear before nine months or more after birth. In the female the antlers are somewhat smaller, thinner, and less branched than in the male, and are retained through the winter until the breeding season in spring, after which they are cast. 'The male, on the other hand,' Darwin notes, 'casts his horns much earlier, towards the end of November. There is great variability in the antlers; there is a "bez tine" as well as a "brow tine," which are peculiar in being either branched or palmate.' In summer the Lapland reindeer feeds chiefly on the shoots of willow and birch, while in winter it depends mainly on lichens such as the so-called reindeer

on the food-supply. Moreover, by leaving the lowlands in spring they free themselves from the gnats and gad-flies, which trouble them very seriously. Domesticated reindeer have been introduced with great advantage and success into Alaska, Newfoundland, Labrador, and some parts of North-west Canada. It is said that the Lapps have to move their herds near the coast in the summer if the health of their stock is to be preserved, and sometimes an immense herd will rush in a head-long race to the sea.

In North America and elsewhere the reindeer is hunted for the sake of its flesh, fat, and hide. It is shot or trapped in snow-pits. The flesh and fat are used in a fresh state or made into pemmican. The skin is used in many ways—for clothing, bedding, and the like. To the Laplanders 'the reindeer serves as a substitute for horse, cow, sheep, and goat,' but its domestication is not very complete. It constitutes the chief part of the Lapp's wealth, and some possess tame herds of two thousand or more, which feed chiefly in the mountainous regions in summer and in the lower grounds in winter. The animal can maintain a speed of nine or ten miles an hour for a long time, and can easily draw a weight of two hundred pounds besides the sledge. Almost every part of the dead animal is used in some way. The reindeer also yields excellent milk.

Reindeer Moss (*Cladonia rangiferina*), a lichen of great importance to the Laplanders and other inhabitants of the northernmost regions of Europe and Asia, as forming the chief winter food of the reindeer. It is found in almost all parts of the world, but is most abundant and luxuriant in Arctic regions. It is a very variable plant,

but always consists of a much-branched erect cylindrical tubular thallus, with small perforations in the axis. It attains a height of two inches and upwards. Its nutritious qualities depend on Lichenin (q.v.), and though acid it may be used as human food.

Reineke Fuchs. See REYNARD THE FOX.

Reinhardt, MAX, born in 1873 at Baden bei Wien, appeared as an actor at Berlin in 1894, and as director of the Deutsches Theater, the Grosses Schauspielhaus, and Die Komödie there has been associated with a great movement to organise the art of the theatre—declamation, music, scenery, lighting—with a single eye to dramatic effect, classical, symbolical, or realistic, as each play may require. One of his novelties is to extend the stage right into the centre of the auditorium, and another to mingle spectators and actors in 'crowd' scenes, his chief aim being to restore the intimacy that existed in Greek and Elizabethan theatres. See monographs by Jacobsohn (1911) and by Stern and Herald (1919).

Reinkens, JOSEPH HUBERT (1821-96), was born near Aix-la-Chapelle, where he worked in a factory before he studied for the priesthood. In 1853 he became professor at Breslau, and in 1873, a strenuous opponent of the infallibility decrees, was chosen bishop by the Old Catholics (q.v.).

Réjane, GABRIELLE (1857-1920), French actress, daughter of an actor, made her *début* in 1875 at the Vaudeville. Endowed with a marked personality she had a successful career at the Vaudeville, Odéon, Variétés, and Ambigu, but her greatest triumphs were achieved in Richépain's *La Glu*, and Sardon's *Madame Sans-Gêne*. She made several foreign tours, visiting England for the first time in 1894.

Relapsing Fever (also known as *famine-fever* and *seven-day fever*), is one of the three great

Reindeer (*Rangifer tarandus*).

moss. It seems that they use both their antlers and their hoofs in removing the snow which hides their food. The animals run swiftly, but not gracefully, taking long sliding strides, and their hoofs snap together as they run. In their natural life the reindeer are gregarious. They migrate from the mountains to the lowlands in winter, and return again in spring, a change in part dependent

species of continued fever, the two others being typhus and typhoid. It was first definitely discriminated from these diseases by Dr Henderson of Edinburgh and other Scottish physicians about 1842, but it can be traced back with certainty in the records of disease a century farther, when it was prevalent in Ireland and Scotland. During the 19th century it was met with in those countries, in England, in central and eastern Europe, the countries surrounding the Levant, North Africa, India, China, and, though never extensively, in North America. Relapsing fever usually begins suddenly with rigors, a sense of chilliness, and frontal headache. Febrile reaction soon sets in, with a temperature of 104° or more, and pulse usually over 100 per minute; the tongue is coated with a thick moist whitish fur; and the skin is often jaundiced (a symptom that seldom occurs in typhus or typhoid fever). There is severe aching pain in the joints and muscles, and great sleepiness; but delirium, if present at all, usually comes on only towards the end of the first week. After the above-described symptoms have lasted for a period varying from five to eight days, generally on the seventh day, a sudden change takes place. This *crisis* commences with a copious perspiration, which is followed by a rapid falling of the pulse and temperature to or below the normal, and the patient appears nearly well. But from the fifth to the eighth day of this seeming convalescence a sudden relapse occurs, and all the primary symptoms return; these often run a rather shorter course than before, and again terminate in sweating and in a second convalescence, which is in most cases permanent. The relapse sometimes, however, occurs three or even four times. Death is a rare termination of relapsing fever; and when it does occur, it is usually before the seventh day of the disease. No important anatomical lesion is constantly observed in the bodies of those who succumb to this disease, except enlargement of the spleen. One form of the disease, however, is much more severe, and very often fatal. It was originally described as a distinct disease under the name of *bilious typhoid*, and is characterised by more marked implication of the digestive organs, by the constant presence of jaundice, and by absence or incomplete development of the crisis and intermission. It has now been shown to be really identical with relapsing fever proper. Relapsing fever is generally met with among those living under unfavorable hygienic conditions; it is specially apt to attack a population suffering from insufficient nourishment (hence the name famine-fever), and is seldom met with among the upper classes, or among Europeans residing in the tropics, unless they are brought closely in contact with the sick. At the same time it is very infectious, spreading either directly from the patient to doctors, nurses, &c., or from clothes and bedding to washerwomen, who have suffered severely in some epidemics. It was shown by Obermeier of Berlin in 1873 that an organism (*Spirillum*, q.v.) is constantly present in the blood of those suffering from the disease, and his results have been confirmed by numerous other observers. Moreover, a similar disease has been produced in monkeys by inoculation with the organism, which has also been found in their bodies after death. There can be no doubt, therefore, that this spirillum is the cause of the disease (see GERM THEORY OF DISEASE). Though relapsing fever has been abundantly proved to be distinct from typhus, they are often associated in a curious way; epidemics of the two diseases have frequently been observed to occur in the same place either simultaneously or successively.

Treatment.—The patient, as in other febrile

diseases, must be kept in bed, and soporifics and aperients are frequently necessary. Salvarsan or other preparation of arseno-benzol has the same destructive effect upon the spirillum causing this disease that it has in syphilis, and a single injection into the veins is often sufficient to cut short the fever and prevent relapses.

Relations, MAINTENANCE OF. In England it is the duty of the husband to maintain his wife, according to his estate or condition in life; if he refuses or neglects to do so, or makes it impossible for her to live with him, she has an 'authority of necessity' to pledge his credit for the necessities of life. Under the statutes relating to the poor a husband may be punished for deserting his wife, and compelled to provide for her maintenance; the husband of a lunatic wife may be compelled to contribute to her maintenance in an asylum. The obligation of a husband to maintain his wife ceases if she leaves him without his consent in circumstances which do not justify her in living apart, and in any case if she commits adultery, though he may have been guilty of cruelty or other misconduct. Under the Married Women's Property Act, 1882, a woman who has property may be compelled to contribute to the maintenance of her husband. At the common law a parent is not legally bound to maintain a child; but he may be indicted for not supplying an infant child with necessities. In like manner a child is not bound at common law to maintain his parents. But the poor-law of 1603 imposes a direct liability on the father, grandfather, mother, grandmother, or children of any person not able to work; and by a subsequent act a man who marries a woman having children (legitimate or illegitimate) must maintain such children. The Married Women's Property Act, 1908, provides that married women having separate estate shall be liable for the maintenance of their parents. Bastard children are to be maintained by the mother; but the father may be summoned before justices and ordered to pay a weekly sum to the mother, or to a person appointed by the justices. A grandchild is not liable to maintain a grandparent, nor can a man be required to maintain persons related to him only by affinity (as e.g. a son's wife), or a collateral relation (as e.g. a brother or nephew). In Scotland the father, and failing him the mother, is bound to maintain children until they are able to earn a livelihood; similarly a child is bound to maintain his father. The same applies between descendants and ascendants in all degrees, but not to collaterals. A husband is bound to maintain the indigent parents of his wife during the subsistence of the marriage, but only up to the value of any property he may have received through his wife on marriage. The father and the mother of an illegitimate child are equally and jointly bound to support it, and if the child is unable to earn a livelihood the obligation may last throughout its life. A husband is, of course, bound to support his wife; and he is liable to her creditors for alimentary debts. In the United States the laws of the states vary; but the duty to support wife, children, and parents is generally recognised, and it is usually made a penal offence to abandon wife or children.

Relative Keys. See SCALE.

Relative Rank. See RANK.

Relativity. 1. *The Physical Universe.*—As judged by the information furnished to us by the evidence of the senses, the physical universe seems to us to have an objective existence independent of the observing mind. But in some cases the processes of scientific investigation lead us to conclude that certain of the phenomena of the universe, e.g. the mirage, are unreal, and have a quite different

constitution from those of the phenomena which they seem to resemble. The question naturally arises, May not the apparent realities be themselves unreal? And by one school of philosophers it is asserted that there is no real objective universe at all; that it is non-existent outside the thinking mind; that, in fact, its properties are only attributes and properties of the mind. And it is really impossible to prove or disprove either view. To these philosophers the physicist replies that if their view be correct, so that he is only investigating the properties of mind, he is nevertheless taking the best method of carrying out the investigation. He therefore asserts as a postulate the external objective existence of the universe, and proceeds to investigate its properties as such in accordance with scientific method.

2. *Space and Time: their Relativity and Dimensions.*—The ideas of space in which our universe exists, and of position within it, are impressed upon us through observations which lead us to use such terms as right and left, up and down, far and near; or north and south latitude, east and west longitude, height above or depth beneath mean sea-level, and so on. Three independent and definite statements of these or similar types, e.g. distance north, distance east, and distance up, completely specify position in space. Therefore we say that space is possessed of three independent dimensions, or that it is tridimensional.

Similarly, the idea of time in which existence occurs arises through observations which lead us to employ terms such as before and after, earlier and later, or such prefixes as pre- and post-. One definite statement of such a type, e.g. 5 o'clock P.M., completely specifies the instant of an occurrence. Therefore we say that time has one dimension, or is unidimensional. It may change while position remains fixed, and so we regard it as an entity quite independent of space.

But we cannot specify an instant in time without specifying an instant, or epoch, or origin, from which we measure time forwards or backwards. And we cannot specify position in space without specifying a point or origin from which we measure distances forwards or backwards, in three independent directions—that is, measurements in time and space are essentially *relative*: we may speak of absolute time and absolute space, but we know nothing of them in actual experience.

3. *The Scientific Method.*—In the development of science from a mere body of disconnected facts the attempt is first made to co-ordinate the facts or phenomena into connected groups, and then to frame, by postulation, determining conditions, or rules, or laws, which bind them together. The aim is always to get the *most inclusive*, the *most simple*, and the *most accurate* law attainable. At first it is regarded as a mere working hypothesis. But gradually, as its applicability widens, and in particular when it is found to be capable of predicting previously unknown phenomena, it attains to the rank of an accepted *theory*, though it can never attain to absolute proof.

The simplest law of all is that of constancy, conservation, or *invariance*. The next simplest is that of direct proportionality. A law may be purely empirical, that is, purely descriptive in itself, but it is not then regarded as an ultimate law exhibiting fully the interrelations of phenomena. It does not fulfil the above test of inclusiveness.

4. *Newtonian Relativity.*—Newton's laws of motion, which apply to all mechanical actions in the universe of ordinary matter, were stated without explicit reference to any system of axes, or any origin of position or of time (sect. 2), but the essential relativity of measurements in space is implicitly involved in them. If they hold with

reference to any set of axes supposed to be at rest, they hold also with reference to any set which are in uniform rectilinear motion relatively to these. Time is supposed to be essentially the same for both systems of reference.

5. *Action at a Distance. The Aether.*—One of the postulates or laws laid down in the Newtonian philosophy is that no action can take place between distant bodies except by the intervention of a connecting medium. Light comes to us from the most distant stars, and it takes time to traverse the intervening space. Its rate of propagation is known from experimental measurements. It has some location in the interval between its departure and its arrival. The medium in which its energy is located is termed the *aether*. Newton considered that, even in a case in which there was no finite rate of propagation of action, there could be no action between distant bodies except through a medium (as in the case of gravitation, for example). His view indeed was that no one competent in matters of philosophic thought could come to the contrary conclusion.

Maxwell investigated the properties of the aether which would enable it to account for electric and magnetic actions occurring apparently at a distance, and he showed that these would be propagated at a finite speed by wave motion in the medium. His idea that these waves were waves of light, and that their speed would therefore coincide with that of light, has been fully verified. He investigated the stresses in the aether which accompany their propagation.

6. *Aberration. Fixed Aether.*—In consequence of the motion of the earth round the sun, which is shared by any observer on the earth's surface, a star is not in general seen in the direction in which it is actually situated. The phenomena is exactly analogous to that observed when one moves through still air in which raindrops are falling vertically. The drops do not appear to be falling vertically, but to move in a direction inclined to that of the observer's motion. The displacement of the star is exactly that which would occur if light moved with its known constant speed through the aether at rest, while the earth moved freely through that aether without disturbing it in any way. This is the doctrine of a *fixed aether* serving for the propagation of light, and, according to Maxwell, of all electro-magnetic action.

But in order to explain the observed slower speed of propagation in a more refractive medium than aether in free space, it is necessary to assume that the aether is denser in a more refractive medium (e.g. water or glass) than it is in free space. To explain the facts Fresnel assumed that the excess of the density in matter over that in free space is carried completely by the matter in its motion through the aether, while the proportion of the aether having the same density as in free space moves freely through the matter, or, rather, lets the matter move freely through it. It is in this sense that the term *fixed aether*, above introduced, is used. Fresnel's assumption is found to agree entirely with experiments regarding refraction.

7. *Michelson's Experiment. Moving Aether.*—Now, if a boat is rowed at a constant rate relative to the surface of a stream, it can easily be shown that the time to row it first down and then up stream through a given distance relative to the banks is greater than the time taken to row it across the stream and then back through the same distance. In the same way light, moving with constant speed through the aether, would be expected to take a longer time to pass forwards and backwards between two points at a fixed distance apart on the earth's surface when the line joining them is parallel to the direction of the earth's motion, i.e.

to the direction of the æther-stream, than it would when the line is perpendicular thereto.

When the test was made (by an optical interference method) by Michelson, and later with more delicate apparatus, which could indicate one two-hundredth part of the effect to be expected, by Michelson and Morley, no trace of the effect was observed. This leads directly to the conclusion that the æther is at rest *relatively to the earth*, and is directly opposed to the conclusion drawn from aberration.

8. *The Fitzgerald-Lorentz Contraction.*—Fitzgerald pointed out that the only way of reconciling these discordant experimental results in accordance with recognised physical ideas was to assume that the length of a body was different according as it lay parallel or perpendicular to the direction of its motion through the æther. The length has to be shorter in the former case so as to reduce the time of transit of light to and from along it to the time in the latter case. The change cannot be shown through measurement by a material scale, for the length of the latter is variable in the same way.

Lorentz independently made the same assumption in consequence of theoretical reasoning which led to an extension of the Newtonian principle of relativity. The interaction of æther and matter might produce the contraction.

9. *Lorentzian Relativity.*—Lord Rayleigh pointed out that the contraction deduced by Lorentz from his theory of the propagation of light (electromagnetic waves) through the æther, a theory framed to account for the Michelson-Morley result, would lead us to expect the existence of slight double refraction in matter so stained. Rayleigh made the experiment, and found no such effect. Brace verified his result with still more delicate apparatus.

In the Newtonian relativity the duration of a given event was assumed to be the same for all observers in all conditions of motion—that is to say, time was regarded as an absolutely independent variable (sect. 2). Lorentz showed that, by using a certain set of space and time co-ordinates, differing from the Newtonian set mainly in that the time co-ordinate depended on relative motion, the equations for electro-magnetic (optical) conditions in the free æther were of the same form to *whatever set of axes they were referred* so long as these were in uniform relative motion only. This implies the absence of all observable effects, such as those sought for by Michelson and Morley, and by Rayleigh and Brace. The new idea involved is that of time dependent on position and motion. This relativity reduces to the Newtonian form for motion sufficiently slow in regard to the speed of light. It therefore fits its ordinary mechanical as well as electro-optical facts.

10. *Einsteinian Relativity. First Form.*—The motion of a Lorentzian set of axes was supposed to be given with reference to a set regarded as fixed relatively to the æther. And Lorentz's investigation was designed to determine conditions under which the above mentioned optical effects would necessarily be as found. Einstein asserted that physical laws, found true relative to one set of axes, were unaltered in form if referred to another set which was in uniform rectilinear motion with respect to the former. This states the conditions of invariance (sect. 3) of physical laws. Einstein postulated also the invariance of magnitude of the speed of light relative to any system of co-ordinate axes whatever be its state of uniform rectilinear motion. From these postulates he deduced (sect. 12) the Lorentzian conditions of relativity. The difference introduced now is that *these conditions follow as consequences of an asserted universal law*, whereas they were formerly introduced to account for certain particular phenomena. All physical

phenomena—at least apart from gravitation—are now postulated to be subject to it. Thus no measurements designed to exhibit motion relative to the æther can succeed. This is in accordance with hitherto observed facts.

11. *Second Form. Gravitation.*—In Newtonian (or, rather, Galilean) relativity, in Lorentzian relativity, and in the first Einsteinian relativity, invariance of laws was asserted with reference to any set of axes in *uniform* rectilinear motion with respect to a set for which the laws were found to be true. In his second form of relativity Einstein generalised this condition so as to include invariance of all physical laws relatively to all sets of axes whatever be their state of relative motion. The state need not be steady whether with regard to translation or rotation.

Newton proved that weight was proportional to mass (or inertia), and essentially defined force as the product of mass and acceleration. But it does not follow that weight bears the same proportion to inertial mass as other forces of equal magnitude do. A comparatively recent experiment (1891) by Eötvös gave strong support to the view that the proportion is the same. Einstein made the postulate that it is the same, and thus succeeded in including gravitational laws within the scope of the theory of relativity. This postulate is the basis of the second form of his theory, just as the postulate of the constancy of the speed of light under all conditions was the basis of its first form, or as inertial invariance was the basis of Newtonian relativity.

No quite satisfactory theory of gravitation has ever been proposed, nor does Einstein's re-foundation of the principle of relativity furnish one. But it does enable gravitational phenomena to be described formally as if they were merely motional effects stated relatively to a suitably moving set of axes. In illustration of this statement, consider a person weighing 10 stones standing on a lift at rest. If he is suddenly loaded with 1 stone weight more, he may, judging by the pressure of his feet on the floor, decide that his weight has been increased by one-tenth. If the lift be now suddenly set in upward motion with an acceleration of rather less than 3 feet per second, he would, if the motion were outside his cognisance, consider that his gravitational tendency had again increased by one-tenth. The two effects would be indistinguishable to him, for he refers everything to axes fixed relatively to the lift. But in the latter case his axes are actually moving with vertical acceleration relatively to the earth, and the apparent gravitational effect can be accounted for by reference to a parallel set of axes fixed relative to the earth without any allusion to gravitation. Another example appears in the case of an equatorial observer, to whom, were the earth rotating at about seventeen times its present rate, gravitation would seem to be nonexistent because of the action of the so-called centrifugal force.

12. *Second Form. Velocity of Light.*—In this generalised system of relativity it follows that, just as in the first system the invariance of the speed of light compelled departure from the simple inertial invariance of the Newtonian system, so here the new postulate compels departure from the constancy of the speed of light except in a uniform gravitational field. The theory shows that the speed of light is less in a region of strong gravitation than it is at a great distance from any gravitative body. Hence light is in general refracted in passing through a non-uniform gravitational field, being deflected towards the region of stronger gravitation. This predicted effect has been verified within observational errors, in the case of starlight passing near the limb of the totally

eclipsed sun, both as to its direction and magnitude. Another successfully undergone test of the theory is that of the direction and magnitude of the motion of the perihelion of Mercury, which does not seem to be explainable on the unmodified Newtonian theory of gravitation. One more successful test lies in a predicted change of wavelength of light emitted in a very strong gravitational field. The experimental proof is difficult because of the smallness of the effect even in the strong field of the sun. But the verification has recently been made still more stringent by observation of light coming from the intensely dense small component of the double star Sirius.

13. *Euclidean Space. Curvature of Space. Space-Time Co-ordinates.*—If, in a limited plane space of two dimensions, we draw a right-angled triangle, Euclid's proposition that the square on the hypotenuse is equal to the sum of the squares on the two other sides holds true. Such space is called *Euclidean* or *Homaloidal*. The proposition does not hold in *curved* space of two dimensions, e.g. on the surface of a sphere, the sides of the triangle being portions of great circles.

If, in our tridimensional space, we draw from the right-angled corner of the plane triangle a line perpendicular to the triangle, and complete the rectangular block with the three coterminous sides as edges, we find that the square on the line joining that corner of the block to the opposite corner is equal to the sum of the squares on the three consecutive edges which together join these corners. So our space is called tridimensional, Euclidean, or homaloidal space. Similarly we can treat of four and higher dimensional spaces, though, from our limitations in nature, we cannot picture them to ourselves.

In Newtonian relativity the distance between two points not in relative motion in our space is quite independent of time, and the Euclidean relationship holds. In Lorentzian, and in Einsteinian relativity of the first kind, a relation subsists between the three space co-ordinates and the time. The distance between the points is not regarded as independent of the observer's motion relative to the points. The relation which was found to suit the results of the Michelson-Morley experiment and others, together with the assumed independence of the speed of light of all uniform relative motion, is that, in the propagation of light between two near points in free space, the sum of the squares of their component rectangular distances is equal to the square of the speed of light multiplied by the square of the interval of time taken by light to pass between the two points. We may express this by saying that the square of their optical distance is equal to the sum of the squares of their co-ordinate distances. This is the law which compels the physical invariance referred to in section 10. It may be represented geometrically by means of a space-time rectangular complex of four dimensions in which the product of the speed of light into the interval of time, multiplied by the ordinary imaginary factor—the square root of negative unity—is measured in the fourth rectangular direction. That four dimensional complex forms a *Euclidean space*. The statement that it is Euclidean expresses the first form of Einsteinian relativity. But it must be remembered that it is not a *real* four dimensional space: it is purely pictorial. A scheme of its representative points would indicate the past, present, and future of our material universe, apart from gravitational effects except in a region so small that the gravitational force is practically uniform throughout it.

For a field of varying gravitation we cannot find a set of rectangular space-time axes so moving as to simulate the field throughout its whole extent

by means of the accelerations: witness the various values of the planetary years. In other words, the above law regarding sums of squares does not hold. We must regard the space as non-Euclidean except in so far as it may be practically so throughout any sufficiently small region. It must be curved slightly in a fifth dimension. The above law regarding sums of squares therefore requires slight modification, and products of co-ordinate distances are brought in.

It is easy to see how curvature of space may give rise to the idea of a gravitative force. Consider two dimensional plane (therefore Euclidean) space. An observer limited to it learns by experience that if he moves with given speed in a circle of radius R , he is subject to an apparent centrifugal force which is inversely proportional to R . Suppose that, unknowable to him of course, his plane space becomes uniformly curved into a spherical surface of great radius. If he now repeats his experiment, measuring the same length R along the curved surface, as he must, he will find that the centrifugal force measured parallel to the surface, which is all that he can judge of, is less than the value which he would expect from his previous experience by an amount proportional to R . He would ascribe this naturally to a central gravitative force directly proportional to the distance.

14. *Existence of the Ether.*—Extreme relativists, seeing that in their scheme light moves in free space, apart at least from gravitative action, with the same speed between two fixed points *whatever be their condition of uniform motion*, assert that the ether has no real existence. The extreme form of the theory approaches more nearly to the standpoint of the idealistic philosophy (sect. 1). For the physicist Newton's view still holds (sect. 4). He cannot disprove the assertion, but neither can the extreme relativist deny the opposite assertion (sect. 1). The physicist feels compelled to seek 'the reason of the cause and the wherefore of the why' expressed in terms of ideas consonant with an understood mechanism if that be possible, or at least a mechanism presenting analogies to others whose mode of action is understood. But the condition of equal speed of propagation of light upstream or down-stream is, if there be no other way of describing conditions, a fundamental difficulty.

Stokes long ago showed that aberration (sect. 6) could be explained in consistency with an ether dragged along with the earth in its motion in such a way as to be at rest, relatively to the earth, at the earth's surface. His postulates were not quite consistent with all necessary conditions, but can be made so. It follows that, in measurements made at the earth's surface, no effect of ether drift should be observable. Recent observations at high altitudes have given a positive Michelson-Morley effect increasing with the altitude. If the ether motion thus evidenced be found to be non-rotational, a definite proof of the existence of the ether is furnished.

15. *Conclusions.*—The chief phenomena of the physical universe remain, as before, accountable for on established principles. It is only in connection with effects involving extreme delicacy of measurement that the necessity for addition or modification arises. The new theory states a relationship, hitherto unused, amongst the measurements of space and time in connection with physical actions. It is purely a mathematically descriptive formula that is used. It tells nothing of itself apart from its use in connection with principles already recognised, such as the Maxwellian principles of electro-magnetic action, or that of the Newtonian gravitational potential, except in so far as it may necessitate very slight modification thereof. Never-

theless it has introduced great descriptive unification throughout the whole field of physical science, and has already been extended by further generalisation. It links up the phenomena of gravitation, hitherto isolated, with the whole range of mechanical phenomena, and is in touch with the recent development of ideas concerning these. It satisfies the test of a scientific theory (sects. 3, 12).

It must be regarded as the most wide-reaching and searching development in *dynamics*, if not since Newton's time, at least since the introduction of the Hamiltonian principles of action; as it also is, in physics generally, the greatest since Maxwell's unification of optical, electric, and magnetic phenomena.

Relativity of Knowledge. The doctrine of the relativity of knowledge is almost a commonplace in some philosophical schools, and is as strenuously denied by others. It is connected primarily with the contrast between the absolute and the relative, or the noumenon and phenomenon, and is one phase of the great discussion as to the relation of knowledge to reality. In its modern form the doctrine has obtained currency chiefly through the speculations of Kant, of Hamilton, and of Herbert Spencer. Knowledge evidently implies a knower and a relation between the knower and the object known. Hence it is argued that the object is conditioned by the relation into which it is brought; merely by becoming an object the thing as it is in itself undergoes a change or accommodation. Our knowledge therefore can never yield us the reality of things—the noumenon or thing-in-itself—but only the phenomenon, the thing as it appears to us. Or, as it is otherwise expressed, in being known the object must conform to the nature of the knowing faculty, the mental constitution or organisation of the knower; we cannot, therefore, conclude, says Hamilton, that the properties of existence are known 'in their native purity and without addition or modification from our organs of sense, or our capacities of intelligence.' Hamilton's general conclusion is: 'Of things absolutely or in themselves, be they external or be they internal, we know nothing, or know them only as incognisable; and we become aware of their incomprehensible existence only as this is indirectly or accidentally revealed to us, through certain qualities related to our faculties of knowledge. All that we know is therefore phenomenal, phenomenal of the unknown.' This is adopted by Herbert Spencer, and made the basis of his theory of knowledge, or rather of what Ferrier would have called his agnology, his doctrine of our necessary ignorance: 'The reality existing behind all appearances is, and must ever be, unknown.' In Kant a similar doctrine is associated with the asserted subjectivity of the forms of space and time; but it is also based upon the broader consideration that perception can give us 'only the relation of an object to the subject, not the inward essence which belongs to the object in itself.' The empirical schools, which resolve our knowledge into impressions of sense manipulated according to the laws of association, likewise accept in its widest sense, as J. S. Mill points out, the doctrine of 'the entire inaccessibility to our faculties of any other knowledge of things than that of the impressions which they produce in our mental consciousness.' But, inasmuch as they in many cases profess a sceptical idealism which denies, or leaves doubtful, the existence of any reality beyond the states of consciousness, their views are less usually associated with the term.

The starting-point of the above argument must be conceded by all. Knowledge obviously implies relation; it exists only through the duality of knower and known, this duality being as necessarily

present in the case of what is called self-knowledge as in the case of knowledge by self of independent objects. But the upholders of the doctrine of relativity proceed to convert this essential feature of intelligence into a proof of the 'impotence' of our faculties. For the term is used in such a way as to imply a taint or defect in our knowledge. Our knowledge is condemned because it fails to realise a certain ideal. The question arises, however, whether the ideal proposed is in any sense legitimate or possible. What is this 'reality existing behind all appearances,' this thing in itself that so persistently evades our grasp? The answer of a sound philosophy would seem to be that this unknown essence or noumenal reality is a fictitious entity of our own creation. The essence or nature of a thing is expressed in its qualities or action; the noumenon reveals itself in the phenomenon. The relativists are in the habit of saying that 'we know only phenomena,' thus making our knowledge of phenomena the ground of our ignorance of the corresponding noumena. But, strictly speaking, it is a misuse of language to say that we know phenomena; the phenomenon is our knowledge of the noumenon. To say that we know phenomena is therefore only a roundabout way of saying that we know, and what we know is the noumenon or thing-in-itself. Of course the contrast between knowing and being is not abolished according to this view; in human knowledge, at all events, the existence of objects is independent of our knowledge of them. It is this contrast between the thing as existent and the thing as known that lends plausibility to the doctrine of relativity. But the contrast only justifies us in saying that knowing a thing is not the same as being that thing; whereas the relativistic doctrine says that, *ipso facto*, to know a thing is not to know the reality of the thing. Knowledge, in this view, infallibly cuts us off from knowing.

Apart from this general line of thought, the doctrine is frequently based upon the large extent to which sensation enters into all our knowledge. In the structure of their sense-organs different living creatures differ appreciably, and there will be a corresponding difference in the image of the world which they make to themselves. The knowledge of every being, it is argued, is thus inevitably conditioned by its organisation, and there is no possibility of arriving at an objective criterion. Man, in the Protagorean formula, is the measure of all things; but he measures them only as they seem to him. Such a formula may be interpreted either in a sensationalistic and individualistic fashion, as seems to have been done by Protagoras, or in a rationalistic and humanistic fashion, as is seen in Kant. The former interpretation leads to a sceptical dissolution of knowledge, for it leaves no common ground on which individuals might meet. Kant, by making space and time, if not the categories also, forms peculiar to the human intelligence, but common to all men, provides for objective truth between man and man, but insists on the merely human and relative character of such truth. Apart from the assertion of the merely subjective character of space and time, which Kant can hardly be said to have proved, it is evident that the relativist argument applies with most force to what are called the secondary qualities, such as tastes, smells, sounds, and colours. But when we consider the elevated pleasures of which the last two, at all events, are the source, we may well hesitate about pressing the relativistic argument too far. Things do not exist on their own account as bald brute facts, on which intelligence afterwards supervenes, to make what use of them it can. It seems truer to believe that to be known and enjoyed by spiritual beings is the

purpose of their existence. The relativity of the world to the human senses and intellect would then form no ground for believing that the image of the world thus obtained was in any sense distorted or untrue. We may rise to higher insight and more perfect æsthetic appreciation, but that our knowledge is finite and subject to revision does not deprive it of validity or objective truth in its own time and place. The case for the relativity of knowledge will be found strongly put in Sir W. Hamilton's *Discussions and Lectures on Metaphysics*, Mill's *Examination*, Mansel's Bampton Lectures, and Herbert Spencer's *First Principles*.

Relics (Gr. *leipsana*, Lat. *reliquiæ*, 'remains'), personal memorials of those among the dead who have been distinguished during life by eminent qualities; especially, in the history of the church, objects which derive their value from their connection with our Lord and with the saints; as, for example, fragments of our Lord's cross or crown of thorns, portions of the dust, the bones, the blood, the instruments of torture, the chains, &c. of the martyrs, the mortal remains, the clothes, the books, and other objects of personal use of the other saints. With them may be grouped objects to which a certain indirect sacred interest is given by their being brought into contact with the direct memorials of the distinguished dead, as by their being placed on the tombs of the martyrs, touched with the relics, or blessed at the shrine or sanctuary of the saints, &c. Reverence for relics developed with the increasing honour paid to Martyrs (q.v.).

The earliest monuments of Christian history contain evidences of the deep and reverential affection with which martyrs of the faith, their mortal remains, and everything connected with their martyrdom were regarded by their fellow-Christians, and for which Catholics profess to find warrant in many passages of the Old and of the New Testament, as Ex. xiii. 19; 2 Kings, xiii. 21, and xliii. 16-18; Matt. ix. 20-22; Acts, v. 12-16, and xix. 11, 12. The letter of the Church of Smyrna attests this plainly as to the martyrdom of Polycarp; Pontian's *Life of Cyprion* tells of their stealing the martyr's body, and carrying it away by night in holy triumph. The Apostolical Constitutions bear witness to the honours paid. Miracles, too, are described as connected with relics. Thus, Ambrose tells of a blind man's sight restored by his touching the bodies of the martyrs Gervasius and Protasius; and similar wonders are detailed by Gregory Nazianzen, Chrysostom, and Leo the Great; so that the possession of relics of the martyrs, and even the occasional touching of them, was regarded as a special happiness. According to Theodoret, even cities were content to share with each other portions of the sacred treasure. Connected with this feeling, too, is found a belief of a certain sacred efficacy in the presence or the touch of the relics; and especially there is ascribed by Chrysostom, Basil, Theodoret, and other Fathers, to prayers offered before the relics, a virtue in dispelling or warding off sickness, diabolical machinations, and other evils. Hence we find that altars were erected over the tombs of the martyrs, or at least that relics were invariably placed on the altars, wherever erected; inasmuch that the Trullan Council ordered the demolition of all altars in which no relics had been deposited. Far more sacred than the relics of martyrs was the cross of our Lord, which was believed to have been discovered at Jerusalem by Helena (q.v.), mother of the Emperor Constantine. Minute portions of the wood were distributed to the principal churches; and Cyril of Jerusalem, within less than a century after the discovery of the cross, describes the precious wood as dispersed throughout the world. According to Rohault de Fleury's *Mémoire sur les*

Instruments de la Passion, 'the total cubic volume of all the known relics of the True Cross is about 5,000,000 cubic millimetres, whereas a cross large enough for the execution of a man must have contained at least 180,000,000 or thereby.' The practice of relic-worship, and the feeling on which it was founded, were not suffered to pass without a protest. At quite an early period many abuses and superstitions had crept in, which even the Fathers who admit the worship do not fail to condemn; and Vigilantius, in a treatise now lost, reprobated in the strongest terms the excesses to which it was carried, and indeed the essential principles on which the practice rests. He had so few followers, however, that were it not for the refutation by Jerome of his work against relics we should have no record of his opposition to the popular view; and it is urged by Catholics, as a proof of the universal acquiescence of the church of the 4th century in the practice of relic-worship, that it was not even found necessary to call a single council to condemn Vigilantius.

The writings of Augustine, of Paulinus of Nola, of Ephraim the Syrian, of Gregory the Great, and others are full of examples of the miraculous virtue ascribed to relics, and of the variety and the extensive multiplication of sacred memorials of all kinds. Nor was this confined to the orthodox alone; all the different parties in the controversy on the Incarnation agreed with Catholics and with one another on this subject, and even the Iconoclasts, at the very time that they most fiercely repudiated the use of images, admitted without difficulty the veneration of relics.

In the age of the Crusades a fresh impulse was given to the worship of relics in the West by the novelty and variety of the sacred objects brought home from the churches of Syria, Asia Minor, and Constantinople by crusaders, by palmers returning from Palestine, and by the Latin conquerors of Constantinople; and it is admitted by the most zealous Catholics that at this period many false, and perhaps even absurd and ridiculous relics were introduced, and were successfully commended to the veneration of individuals or individual churches in the West; nor do they venture to doubt that abuse and superstition found their way side by side with what they regard as the genuine and authorised worship of the church. Nevertheless, with the exception of the Waldenses, Wyclif, and a few isolated individuals, the practice remained unchallenged till the 16th century, when, in common with many other doctrines and practices of the Church of Rome, it was utterly repudiated by the Reformers. Catholics, however, allege that the practice, as sanctioned by the church, has nothing in common with the abuses which form the main ground of the objections alleged by Protestants. The Roman Catholic use of relics, as authorised by the church, is to serve as incentives to faith and piety, by recalling vividly to men's minds the lives, and, as it were, the corporeal presence and the earthly converse of the saints, and thus placing before them, in a more touching manner, the virtues which, in the examples, are held up for men's imitation. The decree of the Council of Trent connects the subject of relic-worship with the general question of saint-worship, and regards the relics of the saints not as possessing intrinsic virtue, but only as instruments 'through which God bestows benefits on men.' The Fourth Lateran Council (1215) forbade the sale or veneration of relics until their authenticity had been approved by the authorities; the Council of Trent renewed the prohibition. In the pastoral of the Bishop of Treves, inviting pilgrims to the exhibition of the Holy Coat (1891), it is expressly stated that 'the authenticity of no relic, be it the most eminent of the oldest church of Christendom,

falls under any precept of Catholic faith.' Relics are usually venerated in costly cases or 'reliquaries' set on the altar; they are also carried in procession, and the faithful are blessed with them.

The Greek and other Oriental churches, and most of the Oriental sects, agree with Roman Catholics in the practice of relic-worship. On the contrary, the Reformed churches, without exception, have rejected the usage; though non-religious relic-worship is rife enough, in the form of swords of Wallace and Bruce, locks of Prince Charlie's hair, &c. The practice of relic-worship forms a notable feature of the Mohammedan usage of pilgrimages, and is an even more important feature of Buddhism.

Relief, as distinguished from 'sculpture in the round,' is one of the oldest forms of mural decoration, and in many cases is a subordinate department of architectural art rather than a branch of sculpture proper. It is low relief (*bas-relief*, *bassorilievo*), middle (*mezzo-rilievo*), and high relief (*alto-rilievo*) according as the carved figures project very little, in a moderate degree, or in a very considerable degree from the background. The ancient Egyptians practised a peculiar kind of low relief and *intaglio* combined (see EGYPT). The wall-sculptures of Assyria (q.v.) and Babylonia (q.v.) are mostly in very low relief. The Elgin Marbles (q.v.), from the Parthenon of Athens, are the most notable example of high relief. See SCULPTURE.

Relief Church. See UNITED PRESBYTERIANS.

Relieving Officer. See POOR-LAWS.

Religion.—A word of Latin origin now found in most of the European languages, in some cases replacing the earlier term. As regards its etymology the derivations from *relinquere*, to leave, or *re-eligere*, to choose anew (i.e. to return to the Deity) have found no favour. The choice has usually lain between (1) *religare*, to bind (Lactantius, *Div. Inst.*, iv. 28, cf. Lucretius, i. 931), explained with reference to the restrictions imposed by religion, or the collection of duties incumbent upon man, or the bond with or dependence upon the Deity; and (2) *relegere*, to gather together, reconsider (Cicero, *Nat. Deorum*, ii. 28, 72), with reference to the carefulness and attention to all that concerns the gods. The latter of these is to be preferred. The term *religio* itself has had an interesting history, and two senses can be distinguished: (1) a feeling of awe, anxiety, doubt, &c., one, however, so indefinite that *religiosus* and *superstitiosus* overlapped; and (2) the cult, worship, or system which arose in consequence of, and was founded upon, that feeling. Already in the second century A.D. *religio* could be explained by the word *pietas*, and it could be applied by Christians to Christian feeling and the Christian cult (Minucius Felix).

Although general terms equivalent in meaning to religion can hardly be said to occur elsewhere, both the feeling of awe and a consequent system of behaviour are characteristic of all religions; and modern inquiries into the widespread feeling of the 'numinous' (R. Otto, &c.), and the innumerable tabus and other regulative, restrictive, and disciplinary features of religion, have shown that what is throughout fundamental is the consciousness or awareness of something outside ordinary normal existence which imposes itself upon men and forces them to take a special and considered attitude to it. On the other hand, this primary feeling is by no means necessarily 'religious' in the accepted use of the adjective, and no entirely adequate definition of the term 'religion' has as yet been found. It would be generally agreed that a defini-

tion of religion should certainly cover other than those religions which are for one reason or another considered higher than the rest; moreover, it should, properly speaking, apply to religion alone and differentiate it from morality, art, philosophy, and all that is now regarded as lying outside the term. But a serious difficulty at once arises because often among the world's religions such differentiation hardly, if at all, exists, and there are various types of cult, important for the history of religion, which, to some authorities, do not merit the name of religion. Again, whereas early writers (the Fathers and Schoolmen) were especially concerned with the definition of *true* religion—Christianity as distinct from other religions, or orthodoxy as distinct from heterodox forms—modern writers find it necessary to distinguish between religion and the magic which, though closely resembling it, is to be regarded as its opponent. Accordingly, besides the broad distinction between religion and what is non-religious—one which often can scarcely be drawn—there is a further crucial distinction, no longer between religion true and false, but between religion and magic—again one which can hardly be maintained consistently and rigorously.

Many definitions of religion have been suggested, all beset by the difficulty of gathering together under one head the many sides of 'religious' life and thought. A careful study of them—Leuba (*Psychological Study of Religion*) discusses forty-eight—is a valuable introduction to the nature of religion. The religion of the individual is, typically, something extremely intimate and of the deepest personal worth, often quite incommunicable; it penetrates to a greater or less degree the non-religious aspects of his life and thought; it is an intimate authority to which he is subject, and which absolutely conditions his ideas of God and the Universe, so that 'spiritual' truths far transcend those that are based on scientific and other knowledge. On the other hand, the environment of the individual varies from the more simple and homogeneous to the more heterogeneous and specialised; and such is the varying extent of specialisation and differentiation in communities that the religion of the individual is far from being necessarily that of the group to which he belongs. Again, quite apart from the question of the significance for religion of art, science, political and other philosophies, &c. it often happens that art, philosophy, or political idealism will so be the 'religion' of a man or of men that some distinction must be drawn between whatever subjectively functions as a religion and a more objective estimate. How to form such an estimate would, however, be disputed, and by objective religion could be meant, either religion which has obtained historical realisation, or it may be better to recognise that, as opposed to religion as a subjective spiritual state, with all its manifold forms of expression in history, it is precisely objective religion which it is the goal of the modern Science of Religion to determine. The following may be cited as a recent definition: Religion is a collection of beliefs and practices (or practical attitudes) concerning a reality, personal or impersonal, unique, multiple, or collective, but in some way supreme, upon which man feels himself somehow or other dependent, and with which he desires to enter into relation (Pinard de la Boullaye).

Various attempts have been made to classify religions. The criteria have been *dogmatic*: religions true and false, natural and revealed, or natural and positive; or *cultural*: the religions of savage and civilised races (some would interpolate the semi-civilised), or of nomads, hunters, agriculturists, &c., or book religions and those without

sacred writings. Distinctions have been drawn also between national or race religions and those founded by great individual teachers, between redemptive religions and those in which the idea of an individual saviour is wanting or germinal, and, again, between universal religions and those too closely bound up with social, national, or dogmatic restrictions to be universal. Much more stimulating have been the classifications influenced by evolutionary ideas of some progressive development in the character of religion itself. Especially striking and influential was Hegel's scheme of religions of nature, spirituality, and the absolute or Christian religion. In general all evolutionary schemes are based on the recognition of (1) some extremely rude types of social-religious life among rudimentary peoples, (2) various evident developments from lower to higher types of religion, and (3) certain convictions as to the lines along which development has run and must continue to run. Although different conflicting classifications prevail, each has brought out facts of importance; and although the questions to which investigators have applied themselves can scarcely be said to have been answered, much more is known of religion than even a generation ago, and the modern study of the world's religions is one of the most impressive features of the day.

Four methods of inquiry in what is now a vast field of research may be noticed. (1) The *Comparative* is exemplified in Sir James Frazer's *Golden Bough*, with its collection of material illustrating many different forms of magic, tabu, sacrifice, ideas of the soul, regard for the dead, &c. As in the world of organisms some particular resemblance is perceived and forms the basis of the classification; though whether the resemblances are as significant as the differences, and whether the conclusions based on them are valid, are vital questions that sooner or later arise. The method has brought to light great masses of illuminative material: one passes from the comparison of data to that of different methods of handling the data, from the comparison of religions to that of theologies and philosophies, and the last word may be said to be, not the formulation of some final body of truth but the comparative study of such bodies of truth, religions and other, as are regarded as final. (2) The *Historical* method is concerned with the changes in the religion of a land, people, group, or individual, with the history of particular beliefs or practices, with that of a religion irrespective of land (Judaism) or people (Buddhism), and with the history of religion in the human race. Thus attention is paid to the rise of new religions, their ebb and flow, the decline of a religion and its death or revival. Thereby it is seen that the religious conditions of any one age are simply one stage in a profound process some fuller knowledge of which can be determined by a survey over as large a field as possible. It also becomes obvious that, as the changes which have made religious history turn upon all the individuals concerned, the religion of the individual is psychologically not less important than that of his environment. (3) The *Sociological* method investigates the part played by religion in the great events of family, tribal, and national life, the inter-relation of the constituent social divisions, the preservation of the social group, and its main interests. The relation between social conditions and the contemporary religion is not fortuitous; and besides the rôle of religion in social institutions (on which cf. Frazer, *Psyche*), the relation between the religious and non-religious spheres of life and thought always proves significant. Physical and economic conditions are also of the first importance, whether the scene is laid in the desert or in

mountains; climate is a factor (contrast Persia and India), also the risks attending the food-supply, and even the nature of the staple diet. These and other factors combine to shape the mentality of a people, so that an effective religion becomes the natural and inevitable expression of a people's whole temperament and life. Finally (4), of ever-increasing prominence is the *Psychological* method concerned primarily with the instincts, emotions, and mental processes. Viewing religion from within it illuminates the inner lives of men, ourselves included. Everywhere it tends to find similar fundamental processes, and it relates together in a new way the highest and lowest types of man. It elucidates the natural psychological efficacy of religious beliefs and practices—the tabus, belief in magic, the efficacy of convictions in the efficacy of both amulets and angels. It associates the idea of divine-kingship and hero-worship, the sacred dance and the secular, and the religious and non-religious forms of initiation and other ceremonies, and of conversion, mysticism, and other impressive subjective states. Though still in its infancy and apt to be marred by extravagances, this powerful method is a most drastic dissection and analysis of the individual. It has demonstrated the naturalness of all religion when viewed from the psychological standpoint. But while every man's religion is seen to be explicable, if not self-evident, by reason of his conscious or unconscious presuppositions, psychology is unable to pronounce upon its objective value, or resolve the conflict between opposing or rival religious convictions. Further, what is expressed in terms of Space and Time (e.g. 'another' world, an 'external' power, a 'heavenly' origin or goal) is found to rest upon psychical experiences of a prevailingly uniform type. The religious and non-religious phases of personal experience, whatever they involve and wherever they may lead, cannot be isolated in separate spheres—as is already evident from the usual keen intellectual and rational criticism of all religious data. Hence, although the 'spiritual' truths of God and the Universe stand quite apart from the scientific and other non-religious convictions of Reality, both have their normal place in the individual; and the religious and non-religious ways of feeling and experiencing, of thinking and acting, are so inter-connected that a new stage has been reached in the scientific study of religion.

Of the many theories of the origin and development of religion none has won general acceptance, though all have cleared the air and brought valuable facts to light. The theories postulate an initial event (e.g. a primeval revelation), or a peculiar primitive mental state (fear, belief in ghosts, illusions), or some very rudimentary form of cult (fetichism, totemism, ancestor-worship). Religion, in some way or another thus introduced, is supposed to 'survive,' or stages of development are worked out more or less along genetic lines, beginning, e.g. with some primitive animatism or Animism (q.v.). Such crude views as that religion was invented by priests, or was the tool of a class, and that it was spread, in either case, to further selfish or ambitious aims, wholly ignore psychological facts, the characteristic vicissitudes of religion and its persistence. All theories that imply a survival of religion from past ages evade the problem of its actual origin and the reason of its survival: for the data of religious experience combine with the history of religion to indicate that religion persists and undergoes its innumerable modifications because of the innumerable individuals who accept and adjust current religious ideas, beliefs, and practices which are found to afford a natural interpretation and expression of

certain private and unique types of experience. A theory of the origin of religion must satisfy individuals whose personal experience forbids them to regard their religion as a survival from pre-historic ages. Further, the dominant and practical part played by religion in individual and social life tells against any theory of its *origin* from such an emotion as fear or from such illusions as ghosts; and it is necessary to distinguish between (1) what can evoke a distinctively religious feeling (as can fear and distress) or ideas of another realm (as can dreams and trances, &c.); (2) what might seem to be the most rudimentary religion conceivable; and (3)—what is quite another thing—the actual dawn of religion in the history, whether of the individual or the race.

The most characteristic feature of every effective religion is its function as an indispensable complement. Thus it serves to explain, relieve, and supplement phenomena, experiences, and situations which lie far outside the normal. Man's life and thought are found to be incomplete without it. Unseen powers are an explanation of otherwise inexplicable or abnormal phenomena, and religion offers a present help in time of trouble and an all-sufficing promise for the future. So natural is the psychological function of religion that the dawn of religion may be considered to have begun with the experience of certain typical needs (outside the range of the ordinary experience and knowledge of the time) and their satisfaction. The vividness and intensity of religious feeling at the beginning of a new religion or at periods of its revival, like similar periods in the history of individuals, show how religion will inaugurate some new series of developments. But since the content of every new mystical or religious experience is found to be conditioned by the stage of development already reached, such experiences, whether in the individual or the race, are landmarks, they are turning-points and not starting-points. On ordinary psychological grounds one cannot deny the existence of some sort of religious or spiritual experience among very primitive peoples; but the further back we go the more rudimentary must be the stage of development reached, until it becomes impossible to conjecture what the content of religious experience could have been. Experiences which can only be described as religious have been so normal, powerful, and pervasive that the theory of the origin of religion from some 'primitive revelation' might seem to be psychologically attractive. Now although the term 'revelation' is commonly restricted to particular occasions, which are felt to be so impressive and of such objective force as to require a distinctive term not to be applied elsewhere, revelation of some quality must, on psychological grounds, be regarded as a constant factor in the history of religion, though some of the known types of religion (in totemism and theriomorphism) are already so extremely rudimentary that one can scarcely determine the meaning of 'revelation' in prehistoric ages.

Effective religion (as distinct from mythological and other speculation) is typically concerned with the elemental problems of life. The problem of the food-supply bulks so largely among rudimentary peoples that religious (better 'magico-religious') beliefs and practices to this end presumably predominated from the earliest times. At all events such rites recur among the most rudimentary totemic societies known, and may probably lie behind the remarkable cave-paintings of animals in prehistoric Western Europe. The view that whole peoples are devoid of religion has not been proved, nor, if true, would it affect the problem of the dawn of religion. Similarly the widespread recognition of a Supreme Being, even among very rudimentary peoples (e.g. pygmies), as urged by Andrew

Lang, and confirmed especially by Wilhelm Schmidt, has hardly the significance commonly attached to it, for these great gods usually stand outside the working social system, even as among more advanced peoples a Supreme Being, however freely recognised, is often not so effective as the beings felt to be nearer at hand and more directly interested in men.

The study of mystical, religious, or spiritual experiences has so unmistakably emphasised the remarkably varied results from social, ethical, intellectual, and other points of view that the detrimental, unlovely, and clearly unprogressive aspects of religion are not less significant than those which are recognised as wholly beneficial and as factors in progress. The progressive history of religion is a fact, and some great landmarks are well known, the most notable being the birth of Christianity and the widespread movements five or six centuries earlier. But although Confucius and Lao-tse (vol. iii. pp. 410, 187), Buddha (vol. ii. p. 325) and Mahavira, the founder of the Jains (q.v.), Zoroaster (or a new stage in an earlier Zoroastrianism; q.v.), stand at the head of profound developments continuing to the present day, in Palestine the Deutero-Isaiah (vol. vi. p. 234) and the reorganisation of Judaism (see EZRA) proved an indispensable prelude to Christianity, and a line can be clearly traced from modern Christianity back to the earlier history of religion in Palestine. Not only is this continuity impressive, but the growth of knowledge of Man and the Universe in the Christian world may be contrasted with the relative stagnation of religious and other thought elsewhere, not to mention the fact that some religions, so far from tolerating or acquiescing in scientific and critical research, would essentially preclude or exclude it. Such facts as these need explanation, and a natural history of religion has to recognise (1) the differing inter-relations everywhere between religious activities and the non-religious (science, philosophy, &c.); (2) the admitted qualitative differences in the social and other value of religious experiences and convictions throughout history; and (3) the evidently supreme importance of those factors which have been everywhere operative and account for the stagnation, the death, or the progressive development of religions, and account for the differences everywhere between the religious and non-religious tendencies.

Finally, typical of religion are its striking demands. The history of religion means that man's life and thought are found to be below the best of which he is conscious, and his apprehension of spiritual truths an imperfect approximation. Religion stands for something greater than man's considered account of it; and the religion of the day has constantly been found to be so inadequate as to be regarded as harmful, and a restatement has been necessary. Religion states or implies what are felt to be the ultimate realities of God, Man, and the Universe; and the incomprehensibly profound ideas of the individual's potential place in the Universe and his destiny are latent in many different forms, lower and higher. Religion offers itself as an entirely sufficient explanation and foundation, and it is accepted and approved as such by an act of faith, and some appropriate inter-relation is formed between the religious and the non-religious spheres of the individual's whole life. Thus the data of religion and its history present a vast field for manifold inquiries, and these invariably issue, partly in significant conclusions regarding religion itself, partly in a profounder knowledge of human nature. Throughout, new light is thrown upon the mind, its development, and the manner in which it treats its experiences; and the fact that these inquiries are now con-

cerned equally with theories and philosophies, and the problems of the relation between religious and non-religious experience, makes the modern Science of Religion itself a landmark in the history of religion.

BIBLIOGRAPHY.—Admirable readable books on comparative religion by Clodd, Frazer, Hartland, Lang, &c.; general introductory books by J. Estlin Carpenter, Jevons, Marrett, &c.; an invaluable handbook by C. H. Toy (1913)*; *The History of Religions*, G. F. Moore (2 vols., 1914, 1920)*; *The psychology of religion*, I. King (1910), J. H. Leuba (1912), Thouless (1923), &c.; psychology and philosophy, Galloway (1914)*; special studies by W. Robertson Smith, Durkheim, Flint, and the Cairds; an important critical essay on the comparative study of religions, by H. Pinard de la Boullaye, S.J. (i. History, 1922; ii. Methods, 1925)*; *Encyclopaedia of Religion and Ethics**; the 'Gifford Lectures,' the 'Hibbert Lectures,' *Revue de l'histoire des Religions*, *Archiv für Religionswissenschaft*. Fuller references to the bibliography, which is considerable, will be found in the preceding, especially those marked with an asterisk. Besides the paragraphs on religion in the articles in this work on Assyria, Babylonia, Egypt, Etruria, Greece, India, Japan, Rome, &c., see separate articles on the various religions of the world, sects Christian and other, and religious doctrines, including those on

Remainder in the law of England was an estate in expectancy. Thus, if the owner of the fee-simple, or freehold of lands, gave them by will or deed to A for life, and after his decease to B and his heirs, the interest of B was called the remainder, because, after deducting A's life estate, all that remained belongs to B. A remainder was distinguished from a reversion in this, that in the latter case the land returned or reverted to the owner himself. Remainders were used in settlements for the purpose of fixing the succession and tying up the property, so far as the law would permit. A legal remainder cannot be created after 1926. But all kinds of future interests which could before 1926 be created either at law or in equity may be created by way of equitable interests, e.g. bond may be granted to B in trust for A for life with remainder in trust for A's first son who shall reach twenty-one. See PERPETUITY.

Remak, ROBERT (1815-65), physician and physiologist, became a professor in Berlin, and distinguished himself by microscopic work in pathology and embryology, and by the medical application of electric currents. He wrote works on the development of the vertebrates and on the medical uses of electricity.

Rembang, a town and port on the north coast of Java; pop. 22,000.

Rembrandt. The name 'Rembrandt' was a baptismal name only, which occurs in various forms. Rembrandt's initials were R.H. —i.e. Rembrandt Harmenszoon, or son of Harmen, and his father's full name was Harmen Geritzsoon van Rijn, or Harmen the son of Gerrit, living on Rhine-side. The local indication, van Rijn, is used in deeds after 1600 A.D. Rembrandt is now often called Van Rijn, but never Harmenszoon. At the time of the artist's birth his family was of the lower middle class, and in prosperous circumstances, living at Leyden, and holding property there. From the register of marriages add from a date on

an etching, Vosmaer accepts 15th July 1607 as the true birth date. Rembrandt's father was a miller, and his mother, Neeltjen van Suydtbrouck, a baker's daughter. They had seven or eight children, of whom two died young, Rembrandt being the youngest but one. All the boys were brought up to trade except Rembrandt, whose father wished to give him a classical education; but he had no taste for Latin, so he went to learn painting in the studio of Van Swanenburch, probably in his twelfth or thirteenth year. Orlers says that he worked with Van Swanenburch three years. This master came of a good family, and had visited Italy. Rembrandt's next master was Pieter Lastman, but he stayed with Lastman only six months. He probably returned to his father's house about 1623, and stayed there till 1630. Already he had begun to paint old age; there are several pictures of that date representing old people, as well as careful studies. He began his career as an etcher very early, and etched beggars and picturesque heads, including his own, also a first biblical subject, 'Jesus presented in the Temple.' There are no less than thirty etchings for the year 1630, when the artist was only twenty-three. In the same year he migrated from Leyden to Amsterdam, then a picturesque city of 100,000 inhabitants, and there he set up a studio and took pupils. Already one of the most industrious and productive artists that ever lived, Rembrandt found time to paint several biblical subjects, besides a number of portraits, and to etch forty plates in the year 1631, whilst his progress in art was so rapid that he painted one of his most important masterpieces, 'The Anatomical Lesson,' in 1632, at the early age of twenty-five. He married Saskia van Ulenburgh in June 1634. She was of a good family, twenty-one years old, and the youngest of nine children. The pair settled in a large house in the Bredstraat in Amsterdam. There is good evidence that the marriage was happy, and we know Saskia by the portraits her husband made of her. After marriage he continued to be very industrious, even the year of marriage having a harvest of several religious pictures and many portraits, as well as fifteen etchings. The artist was also in the habit of producing many sketches and drawings. Vosmaer observes that these are either studies from nature or notes taken rapidly, or else embryos of ideas caught as they formed themselves, with a rude pen and a wash, or a few strokes of black stone.

Rembrandt had a daughter, Cornelia, born in July 1638, but she died the month following. A second Cornelia was born in 1640, who also died young, and a son, Titus, in 1641. His father died about 1632, and his mother about 1640, after having been frequently portrayed by her son both in painting and etching. Saskia died prematurely in 1642, after only eight years of marriage. Between the death of his mother and that of his wife, Rembrandt's activity developed itself in three branches, portrait, small biblical or genre pictures, and large canvases with figures the size of life. The year of Saskia's death is also that of the famous picture known as the 'Night Watch.' An important branch of Rembrandt's artistic production from 1643 to 1650 was landscape, which he continued to practise more or less till 1659, both in etching and painting. After the death of Saskia the domestic life of the artist becomes obscure. In 1651 his servant Hendrickje Jaghers had a child by him baptised as Cornelia, and after his death one Catherine van Wijk is mentioned in the register as his widow, but it is unknown whether she was a second or a third wife, and at what date her marriage took place. It is not precisely known what were the causes of Rembrandt's bankruptcy in

1656. He was an ardent collector, willing to give high prices, and as his family fell into embarrassed circumstances, it is likely that he helped them. His art, too, became unfashionable; but he did not relax his diligence. His collection fetched only 5000 florins at the sale. Vosmaer believed, however, that he had found evidence of a return to partial prosperity, and that Rembrandt was able at least to rent a commodious and handsome house near the Rozengracht. After continuing to work with constant energy and undiminished power, he died 8th October 1669, following his son Titus, who died a year earlier. Titus left a posthumous daughter, Titia, and Rembrandt was present at the baptism. He was spared the pain of losing this grandchild, whose death occurred thirteen days after his own. Rembrandt left two children, names unknown.

The genius of Rembrandt has been the subject of much controversy, but his fame has increased, notwithstanding unintelligent censure and praise often equally unintelligent. Rembrandt was not blind to the merits of Italian art, as we know by his collection, but his own practice was founded on the direct study of the nature he saw around him both in human life and landscape. It is a mistake, however, to suppose that he copied nature slavishly, that he was a sort of photographer. Far from that, he was so imaginative that he transmitted everything. He had an equal power of expressing mass and rendering detail both in painting and etching. His technical force in both arts has only been rivalled in other styles, and it has never been surpassed. The common admiration for his chiaroscuro is, however, misplaced. The chiaroscuro of Rembrandt is often false and inconsistent, and, in fact, he relied largely on public ignorance. But though arbitrary it is always conducive to his purpose. In etching the effect of it was often heightened by an intentionally unequal distribution of finish. No artist ever combined more delicate skill with more energy and power. His treatment of mankind is full of human sympathy for all ages and conditions, but his especial study was old age. In his interpretation of the Scriptures he did not seek to give dignity by a factitious magnificence, or by elevating personages above their social rank, but by inspiring respect for them, and interest in them, as they were. At the same time his artist-faculty of idealisation acted in its own way by giving sublimity. Of the great artists Rembrandt is not the most perfect, but he is the most interesting, and his work is full of variety, both in subject and in technical methods. He was a great draughtsman, in his own way, and often a fine colourist as well as a great executive virtuoso both in painting and etching. Rembrandt had much personal influence as a teacher, and many of his pupils became known. His life seems to have been absorbed in work, and he avoided fashionable society, keeping to the burghers and artists.

See the elaborate *French Life* by his countryman Vosmaer (1877), the study by Emile Michel (trans. 1893), the monograph on the etchings by P. G. Hamerton (1894), and *Lives* by Knackfuss (1900), Bréal, Baldwin Brown (1908), and several works by Dr W. Bode (1897-1908). The first catalogue of the etchings of Rembrandt is that by Gersaint (1751), supplemented by Peter Yver, and translated by Daulby of Liverpool (1796). Adam Bartsch followed at Vienna in 1797. De Clausin published in 1824 an edition of preceding catalogues. Wilson (Lond. 1836) issued a new catalogue with original observations. That by Charles Blanc, in two vols. (Paris, n.d.), includes both pictures and etchings, that by Middleton (Lond. 1878) gives the etchings only, and a catalogue privately printed for the Burlington Club in 1877 gave the etchings in chronological order. Vosmaer gave catalogues at the end of his biography, both chronological and classified. A. M. Hind's catalogue

of the etchings (1912) was revised in 1924. F. S. Haden's monograph on the etchings (Lond. 1879) proves that some of the plates attributed to Rembrandt were executed by other hands, probably by pupils. According to a critical study by Professor J. C. Van Dyke, *Rembrandt and his School* (1923), only about 50 pictures are to be assigned to Rembrandt himself, the others being the work of pupils and followers, though they may have been done under his eye, and touched or even signed by him. The catalogues of Rembrandt's works give about 500 pictures, 600 drawings and studies, and 353 etchings. The bent of his mind may be judged of by the choice of subject. Out of the general total of about 1450 works 136 are from the Old Testament, 255 from the New, 23 from classical mythology, and only 12 from history. There are about 440 portraits and 100 landscapes, besides some sketches of animals and many studies not classed. With the single exception of the Bible, Rembrandt got little from books, and his house, so rich in works of graphic art, contained barely twenty volumes.

Remembrancer, KING'S, or **QUEEN'S**, an officer of the old Exchequer of England, whose duty it was to remind the judges of that court at the proper times that such and such things had to be attended to, and also to keep certain records and make out processes. Since the constitution of the Supreme Court (q.v.) the king's remembrancer has been at the head of a department of the central office of that court. The King's and Lord Treasurer's remembrancer is now the general administrator of the crown revenues of Scotland.

Remijia, a genus of Rubiaceæ (see CINCHONA), valuable as a source of Quinine (q.v.). There are over twenty species known, many in Brazil. The name comes from that of the Brazilian physician Remijo.

Remington, PHILIP, inventor, was born at Litchfield in New York on 31st October 1816. He entered the small-arms factory of his father, and for twenty-five years superintended the mechanical department. The perfecting of the Remington breech-loading rifles and of the Remington typewriter was largely due to his inventive skill. He retired in 1886, and died on 4th April 1889.

Remiremont, a town of France (dept. Vosges), stands on the Moselle, 17 miles by rail S.E. of Épinal. The remains of an abbey, founded in 620, are the finest building in the town. The abbess was a princess of the empire down to 1566; the nunnery was suppressed at the Revolution. Textiles, leather, and cheese are made. Pop. 10,000.

Remittent Fever is a name applied to severe types of malarial fever, in which the temperature falls slightly or remits from time to time, but in which there is no complete fall to normal temperature between the paroxysms. See article MALARIA.

Remizov, ALEXEI, born 1877, Russian novelist and exponent of a realism that is tempered with symbolism. He does not aim at exact reproduction, but uses his discrimination in selecting, so that what he describes may be real enough, but the juxtaposition of unrelated elements is apt to be grotesque. *The Story of Stratilatov* (1909), however, is a striking book, the scene being laid in a provincial Russian town. Remizov's style is considered extremely pure.

Remonstrance, THE, a detailed statement of all the king's illegal and oppressive acts, and a vindication of the rights of parliament, laid before the House of Commons by Pym, and carried by 159 votes to 148, after a stormy debate lasting from noon till after midnight, November 22 and 23, 1641. On the question of its being printed the debate began anew with such extraordinary exasperation that an actual conflict on the floor of the House was saved only by the calmness and tact of Hampden. On a division a majority of 23 left the publication free and restrained the printing only until

further order. The adoption of the Remonstrance was felt on both sides to be a crisis in the struggle between Charles I. and the parliament. It kindled afresh the enthusiasm of the country, and hurried the king into more violent and fatal measures. 'The turning-point of freedom or despotism,' says Forster, 'for two more centuries in England was probably passed that night.'

Remonstrants. See ARMINIUS.

Remora, or SUCKING-FISH (*Echeneis*), a genus of fishes sometimes classed not far from mackerels among the Acanthopteron Teleosteans, or referred to a special sub-order Discocephali. The great peculiarity is the suction disc on the dorsal surface of the head. It is formed from a modification of the first dorsal fin, whose spines have become cleft. The sucking-fishes fix themselves very firmly to sharks, sword-fish, turtles, and even to ships. So firmly do they adhere that they are sometimes used in fishing. A line is fixed to the tail; the fish is set free; it discovers a turtle or fish and fastens itself. The fishermen dive after the line if the remora has fastened on to a turtle, or may in other cases simply haul it up. Columbus, or one of his companions, described how the 'Guinean' shoots 'like an Arrow out of a Bowe towards the other fish, and then, gathering the bag on his head like a

Remora (*Echeneis remora*).

purse-net, hold them so fast that he lets not loose till he'd up out of the water.' More precise details have been furnished by other travellers. Several species of *Echeneis* or remora are known from Zanzibar, Cuba, New Guinea, &c. The remora of the Mediterranean was well known to the ancients, and was credited with many feats, such as that of detaining Antony's ship from the battle of Actium. The fish is palatable, and is sometimes eaten after its day's work of fishing.

Removal of Goods. See LANDLORD AND TENANT.

Reuscheid, a town of Rheinland, 6 miles S. of Elberfeld-Barmen, carries on extensive manufactures of ironwares, cutlery, &c. The population, only 22,000 in 1871, is now 77,000.

Rémusat, (JEAN PIERRE) ABEL (1788-1832), Chinese scholar, was born at Paris, and studied medicine, but as early as 1811 he published an essay on Chinese literature. In 1813 he was compelled to serve as hospital surgeon, but in 1814 he was made professor of Chinese in the Collège de France. Of the numerous works that he wrote subsequent to this period we may mention *Recherches sur les Langues Tartares* (1820), a work in some sort preparatory to his great *Elements de la Grammaire Chinoise* (1822). He wrote also on the origin of Chinese writing (1827), on Chinese medicine, on the topography and history of the Chinese empire, and *Mélanges* (published in 1843).

Rémusat was the first to make known in Europe the life and opinions of Lao-Tsze. In 1818 he became one of the editors of the *Journal des Savants*; in 1822 he founded the Société Asiatique of Paris; and in 1824 he was appointed curator of the Oriental Department in the Bibliothèque Royale.

Rémusat, CHARLES (FRANÇOIS MARIE), COMTE DE, a French politician and *littérateur*, born at Paris, 14th March 1797, the son of Augustin Laurent, Comte de Rémusat (1762-1823), who was successively chamberlain to Napoleon and a prefect under the Restoration. His mother (*née* Claire Elizabeth Jeanne Gravier de Vergennes) was born in 1780, married in 1796, became *dame du palais* to Josephine, and died in 1821. Young Rémusat early developed Liberal ideas, and took eagerly to journalism. He signed the journalists' famous protest against the Ordinances of Polignac which brought about the July revolution, and was in October elected deputy for Toulon. He now allied himself with the Doctrinaire party, and in 1836 became under-secretary of state for the interior. In 1840, when the government passed into the hands of Thiers, Rémusat was made minister of the Interior, but soon resigned the office. He was exiled after the *coup d'état* of Louis Napoleon, and thenceforward devoted himself to literary and philosophical studies, till, in August 1871, Thiers called him to hold the portfolio of Foreign Affairs, which he retained until 1873. He died 6th June 1875. Rémusat was long a well known contributor to the *Revue des Deux Mondes*.

Among his writings are his *Essais de Philosophie* (1842); *Abdard* (1845); *L'Angleterre au XVIII^e Siècle* (1856); studies on *St Anselm* (1853), *Bacon* (1857), *Channing* (1857), *John Wesley* (1870), *Lord Herbert of Cherbury* (1874); *Histoire de la Philosophie en Angleterre de Bacon à Locke* (1875); two posthumous philosophical dramas, *Abdard* and *La Saint Barthélemy* (1878), and *Correspondance pendant les premières années de la Restauration* (6 vols. 1883-87).

His mother's *Mémoires* (3 vols. 1879-80) and *Letters* (2 vols. 1881), both of which have been translated into English, proved to be of the greatest interest, and threw a flood of light on the strange society of the First Empire and the character of Napoleon.

Remy, ST (Lat. *Remigius*). See REIMS.

Renaissance is a comprehensive name for the great intellectual movement which marks the transition from the middle ages to the modern world; a movement including a very marked change in attitude of mind and ideal of life, as well as in philosophy, art, literary criticism, political and religious thought. Substantially a revolt against the barrenness and dogmatism of Medievalism, the new spirit claimed the entire liberation of reason, and, passionately recognising and studying the rich humanity of Greece and Rome, aimed at a complete rehabilitation of the human spirit with all the free activities and arts and graces which invested the classical age. It was an escape—at first hesitating, then triumphant—from a life regulated and confined on all sides by ecclesiastical tradition and intellectual tyranny into joyous freedom and unfettered spontaneity. Zeal for the *Litteræ Humaniores* brought forth a new ideal of culture, and the new view of life for which the name of Humanism is used. Renaissance, re-birth, was originally used as synonymous with the Revival of Letters, the revived study in a new spirit of the classical languages and classical literatures of Greece and Rome in all their depth and breadth, interpreted in their own spirit, and divested of the narrow traditional limitations. Greek in especial was practically a new discovery, and a vastly important one; but the knowledge of the

classics was only one side of the movement which permeated and transformed philosophy, science, art, and religion. The new spirit powerfully aided in weakening the power of the papacy, in the establishment of Protestantism and the right of free inquiry. Under its impulse astronomy was eventually reformed by Copernicus and Galileo, and science started on its modern unfettered career; by it, too, feudalism was abolished, and the demand for political liberty began to be raised. Reverence for the Holy Roman Empire and for its ancient rival the papacy was alike decaying; a new sense of nationality was springing up, and national languages began to flourish. To the same general impulse, as causes or effects, belonged also the invention of printing and multiplication of books, new methods of paper-making, the use of the mariner's compass, the discovery of America, and the exploration of the Indian Sea. The fall of the Eastern Empire in 1453 sent swarms of Greek scholars to promote the revival of scholarship already in progress in western Europe. From the nature of the case, it is impossible to fix a definite date for the beginning of the Renaissance; long before the close of the dark ages there were isolated scholars and thinkers who anticipated the new light. In its main elements, however, the movement originated in Italy towards the end of the 14th century, and, attaining its full development there in the earlier half of the 16th, the Renaissance communicated itself throughout the whole of the rest of Europe; France, Germany, England, and other countries participating later in the movement, which in each of them took a somewhat different shape. But Italy was specially the nursing-mother of the Renaissance.

For the first herald of the Renaissance we may go as far back as Dante (1265-1321), who, with all his medievalism of conception, yet by the pristine energy and fullness of his poetry was no unworthy follower of his chosen master, Virgil. The first positive impulse, however, in that direction was imparted by Petrarch (1304-74). Besides suggesting in his Italian *Rime* the old Roman grace, he awoke enthusiasm for the classics by his Latin epic *Africa* and numerous epistles and dissertations. In his old age he tried to imbibe a little Greek at the extremely sorry sources within his reach, and on receiving Homer from Constantinople urged Boccaccio to translate the supreme poet into Latin. Boccaccio did not rest till he had piously, though very imperfectly, rendered into Latin both the *Iliad* and *Odyssey*. A secretary of Petrarch, Giovanni Malpaghino, commonly called da Ravenna, was the most accomplished Latinist of his day, and, wandering as he did all over Italy, communicated the new impulse to distinguished pupils, Barbiaro, Strozzi, Poggio, Bruni, who in their turn propagated it anew from Venice, Rome, Mantua, and elsewhere. Luigi Marsigli's house became a private academy of the new doctrine, a resort of all the promising neophytes of Florence. Caluccio da Salutato, who translated Dante into Latin, having been made chancellor of Florence in 1375, introduced into public documents the stately sonorous periods of the classic style, and so rendered it imperative on all princes and popes of the next age to have trained stylists as their secretaries. A like classic transformation was effected in epistolary correspondence by Gasparino da Barzizza, who made a special study of Cicero's letters. The glory of having been the first Florentine to visit Byzantium for the sake of learning the sacred Greek belongs to Giacomo da Scaparia. To Salutato and Palla degli Strozzi is due the foundation of a Greek chair at Florence; and in 1396 Manuel Chrysoloras, a genuine Greek in the flesh, began his instructions from the Greek

chair. Chrysoloras planted schools also at Rome, Padua, Milan, and Venice. In the earlier period of the Renaissance Florence leads the van. The president of the republic, Cosimo de' Medici, himself a scholar, theologian, philosopher, musician, financier, a connoisseur in painting, sculpture, and architecture, figures as the magnificent Mæcenas of the new learning, founding the Platonic academy, and opening his hospitable house to all the wits at home and all the distinguished visitors attracted thither. The son

perhaps of the merchant-princes of Florence, sent to Greece for countless volumes of MSS., and constantly kept copyists employed. Niccolò de' Niccoli spent his whole fortune in buying MSS. or procuring copies. Poggio Bracciolini, one of the most eminent of the scholars of his time, rescued Quintilian from a 'foul prison' and transcribed him, and copied with his own hand MSS. of Lucretius and Columella, while he also unearthed Italicus, Manilius, and Vitruvius. Though for fifty years chancellor in the Roman Curia, he directed the most poignant satires against the church. Vespasino da Bisticci (1421-98) was perhaps the last of the mediæval scribes, and the first of modern booksellers; he was agent of Cosimo, Nicholas V., and Frederick of Urbino, supplier of MSS. to Hungary, Portugal, Germany, and England, and the largest employer of copyists in Europe, whom, too, he personally superintended.

The second period in the history of the Renaissance is distinguished by indiscriminate avidity for everything classic. As its most representative scholar may be cited Francesco Filelpho (1398-1481). Having studied rhetoric and Latin at Padua, he learned Greek at Constantinople, became professor at Venice, Bologna, and Florence, and gained the admiration of all Italy for erudition. In the third period of the Renaissance the leading figures are Lorenzo de' Medici and Politian at Florence, Boiardo at Ferrara, and Samazaro at Naples. President of Florence from 1469, and himself of the most versatile talent, Lorenzo de' Medici was, like his grandfather Cosimo, his son Giovanni (Leo X.), and his nephew Giulio (Clement VII.), a munificent patron of learning. By the consent of all, the most consummate of the humanists is Politian, whose *Monto*, *Ambra*, and *Nutritia* display almost as spontaneous a command of the classic languages as do his *Orfeo*, *Stenze*, and *Rime* of his native Italian. Towards the end of the 15th century mere erudition began to sink in credit, and the accomplished personages who adorn the fourth period are of a somewhat more independent type—the historians, Guicciardini and Machiavelli, the handsome Bembo, the splendid Alberti, Castiglione, the author of *Il Cortegiano*, and Ariosto, author of *Orlando Furioso*, the *Cinque Canti*, and the polished cynical *Satires*.

Some of the faults of the Renaissance clung to it in all its periods. At one time pedantry threatened to check originality and spontaneity; the worst ancient works were prized more than the best written in any new European tongue. Petrarch valued himself mainly for his Latin works, and thought lightly of his Italian poems. The tendency was established to regard the classics as the one standard of learning and the one instrument of education. A worse fault was that the revolt against mediæval religious tradition was accompanied to a very large extent by absolute and anti-Christian immorality and license. Literary and artistic refinement placed no check on brutal lusts and savage passions; though in a few men

of high character, Michelangelo, Raphael, Pico della Mirandola, Ficino, and others, in whom Humanism did not extinguish the principles of Christianity and morals, a singularly noble and complete humanity was displayed. The culmination of the Renaissance in Italy may be regarded as having fallen within the half century 1456-1500; and its close for the land of its birth may be fixed at the sack of Rome in 1527 by the Constable de Bourbon, followed by the transference of Humanism in its later developments to France, England, and the rest of Europe.

In Germany the change was as marked as in Italy, but the Humanism of Germany and the Low Countries was very different in spirit from that of Italy. Not less tinged by a revived love for ancient learning, it was never divorced from morality nor hostile to Christianity; and its most important direct outcome was the Reformation. Biblical and Oriental studies were strenuously cultivated. Amongst the noted leaders were Erasmus, Melancthon, Rencblin, and Von Hutten. In the Netherlands and Flanders the new school of painting was a notable development. In France the movement had rich results in art and letters. Villon, Marot, Ronsard, but above all Rabelais are types of the French Renaissance in pure literature; while within the sphere of scholarship and religious reform we have here the names of the Scaligers, Dolet, Muretin, Cujacius, Salmasius, Casaubon, Beza, Calvin.

In England Wyclif and Chaucer may be regarded as the forerunners of the Reformation and the Renaissance; but the main streams of both these movements reached England contemporaneously. In scholarship the great names are Grocyn, Linacrie, Colet, Ascham, and More; but the fullest English outcome of the Renaissance was the glorious Elizabethan literature, with Spenser and Shakespeare, and in philosophy Bacon, as its most noted representatives.

RENAISSANCE, in Architecture, the style which succeeded the Gothic, and preceded the rigid copyism of the classic revival in the first half of the 19th century. Under the heading ITALIAN ARCHITECTURE we have traced the rise and progress of the Renaissance in the country of its birth. The spread of classical literature during the 15th and 16th centuries created a taste for classic architecture in every country in Europe. France, from her proximity and constant intercourse with Italy, was the first to introduce the new style north of the Alps. Francis I. invited Italian artists to his court during the first half of the 16th century. The most distinguished of these were Leonardo da Vinci, Benvenuto Cellini, Primaticcio, and Serlio. These artists introduced Italian details, and native architects applied them to the old forms to which they were accustomed, and which suited the purposes of their buildings, and thus originated a style similar to, though diverse from, that of Italy.

The Italian buildings, besides many palaces and domestic structures, comprised a large number of churches, St Peter's being the great model. In France (as in the other countries north of the Alps) the stock of churches was greater than was required. The grand domestic buildings of Florence and Rome were constructed for defence externally, and were founded in design on the old mediæval castles, which the nobles occupied within the cities. The domestic architecture of France is rather taken from the luxurious residences of the monks, and the pleasant open villas in the country; so that, although very graceful in outline and in detail, its buildings want the force and grandeur of the Italian palaces.

In the French Renaissance so much are the old

Gothic forms and outline preserved that the buildings of Francis I. might at a short distance be mistaken for Gothic designs, although on nearer approach all the details are found to be imitated from the classic. Such are the palaces of Chambord (q.v.)

Fig. 1.—Château de Chambord.

and Chenonceaux (q.v.) on the Loire, Fontainebleau, and many others. The churches of this period are the same in their principles of design. Gothic forms and construction are everywhere preserved, while the details are as nearly classic as the designers could make them. St Eustache, in Paris, is one of the finest examples of this transitional style.

From the middle of the 16th to the middle of the 17th century a style prevailed which may be said to exhibit all the varieties of the Renaissance. This style, usually known as that of the time of Henry IV., may be distinguished by the constant use of pilasters, broken entablatures, curved and contorted cornices, architraves, &c., all applied so as to conceal rather than to mark and dignify the real uses of the features of the buildings. The Tuileries, wrecked by the Commune, showed all these defects. Many of the features of this period are imitated in the so-called "Queen Anne style" of the present time (see below). From this debased style architecture gradually recovered, and during the 18th century a style more becoming the dignity and importance of the *Grand Monarque* was introduced. The classic element now began to prevail, to the entire exclusion of all trace of the old Gothic forms. Many very large palaces are built in this style; but, although grand from their size, and striking from their richness and luxuriance, they are frequently tame and uninteresting as works of art. The palace of Versailles (q.v.) is the most prominent example. The two Mansards, one of whom designed Versailles, had great opportunities during this extravagant epoch. Their invention of giving a row of separate houses the appearance of one palace, which has ever since saved architects a world of trouble, was one of the most fatal blows

which true street-architecture could have received. The east front of the Louvre, designed by Perrault, is one of the best examples of the style of the age. Many elegant private hotels and houses in Paris were erected at this period. A peculiarity of the style of Louis XIV. is the ornament then introduced, called *Rococo* (q.v.).

The classic Renaissance was completed in the beginning of the 19th century by the literal copying of ancient buildings. Hitherto, architects had attempted to apply classic architecture to the requirements of modern times; now they tried to make modern wants conform to ancient architecture. In the church of the Madeleine, Paris, for

Fig. 2.—Central Pavilion of the Tuileries :
as designed by Des Lorme.

instance, a pure peripteral temple is taken as the object to be reproduced, and the architect has then to see how he can arrange a Christian church inside it! Many buildings erected during the time of the Empire are no doubt very impressive, with noble porticoes, and broad blank walls; but they are in many respects mere shams, attempts to make the religious buildings of the Greeks and Romans serve for the conveniences and requirements of the 19th century. This was found an impossibility—people came to rebel against houses where the window-light had to be sacrificed to the reproduction of an ancient portico, and in which the height of the stories, the arrangement of the doors, windows, and, in fact, all the features were cramped, and many destroyed, in order to carry out an ancient design. The result has been that this cold and servile copyism is now entirely abandoned. The French proceeded to work out

a free kind of Renaissance of their own, which proved itself, as the streets of Paris testify, the liveliest and most appropriate style for the street architecture of the French capital in the late 19th century.

In Spain the Renaissance style early took root, and, from the richness of that country at the time, many fine buildings were erected; but it soon yielded to the cold and heavy 'Greco-Romano' style, and that was followed by extravagances of style and ornament more absurd than any of the reign of Louis XIV. The later Renaissance of Spain was much influenced by the remnants of Saracenic art which abound in that country.

In England, as in the other countries of Europe, classic art accompanied the classic literature of the period; but, the fountain-head being at a distance, it was long before the native Gothic style gave place to the classic Renaissance. It was more than a century after the foundation of St Peter's that Henry VIII. brought over two foreign artists—John of Padua and Havenius of Cleves—to introduce the new style. Of their works we have many early examples at Cambridge and Oxford, in the later half of the 16th century. Longleat, Holmby, Wallaton, and many other country mansions, built towards the end of the 16th century, are fine examples of how the new style was gradually adopted. The course of the Renaissance in England was similar to its progress in France; it was even slower. Little classical feeling prevailed till about 1620. The general expression of all the buildings before that date is almost entirely Gothic, although an attempt is made to engraft upon them classical details. The pointed gables, mullioned windows, ovals and dormers, and the picturesque outlines of the old style are all retained long after the introduction of quasi-classic profiles to the mouldings. This style, which prevailed during the later half of the 16th century, is called Elizabethan (q.v.), and corresponds to the somewhat earlier style in France of the time of Francis I. This was followed in the reign of James I. by a similar but more extravagant style called Jacobean, of which Heriot's Hospital at Edinburgh is a good example; the fantastic ornaments, broken entablatures, &c., over the windows, being characteristic of this style, as they were of that of Henry IV. in France.

The first architect who introduced real Italian feeling into the Renaissance of England was Inigo Jones. After studying abroad he was appointed superintendent of royal buildings under James I., for whom he designed a magnificent palace at Whitehall. Of this only one small portion was executed (1619-21), which still exists under the name of the Banqueting House, and is a good example of the Italian style. Jones also erected several elegant mansions in this style, which then became more generally adopted. In the later half of the 17th century a splendid opportunity occurred for the employment of the Renaissance style after the great fire of London. Sir Christopher Wren rebuilt an immense number of churches in that style, of which St Paul's (see LONDON) was the most important. The spire of Bow Church and the interior of St Stephen's, Walbrook, are also much admired.

During the 18th century classic feeling predominated, and gradually extended to all classes of buildings. In the early part of the century Vanbrugh built the grand but ponderous palaces of Blenheim and Castle Howard, which have a character and originality of their own. To these succeeded a vast number of noblemen's mansions, designed by Campbell, Kent, the Adames, and others. Many of these, like the contemporaneous buildings of France, are of great size and magnifi-

cence; but they are usually tame and cold in design, and a sameness pervades them all. They generally consist of a rustic basement-story, with a portico over the centre, and an equal number of windows on either side. The portico is considered essential,

system of designing buildings—namely, by so arranging their general features as not only to express the purposes they are intended to serve, but in so doing to form the decorative as well as the useful elements of the edifice.

The Travellers' Clubhouse and Bridge-water House in London are admirable specimens of his design. There are no superfluous porticoes or obstructive pediments, but a pleasing and reasonable design is produced by simply grouping the windows, and crowning the building with an appropriate cornice.

As already noticed, a similar style of domestic architecture has been worked out in France; but both there and in England there was a reaction against everything classic, and a revival of mediæval architecture superseded that of classic, especially in ecclesiastical buildings. The most magnificent examples of this style are the Palace or Houses of Parliament at Westminster, and the new Law Courts.

The so-called Queen Anne style, common in recent years, is supposed to be founded on the class of design prevalent at the beginning of the 18th century. The buildings erected at that period were of a very plain and simple order, with classic cornices and details, and frequently with large windows, sometimes divided by mullions. There is occasionally a certain picturesqueness in the arrangements which has been made the most of in the modern revived style. The latter, although taking the name of Queen Anne, is far from adhering to the style of her reign, but is rather a free use of the elements of the early Renaissance or Elizabethan style. It thus combines much of the freedom of the late Gothic with classic detail, to which is added a copious use of features borrowed from the Renaissance of France and Germany. Many large structures have been erected in this style, such as the Royal Colonial Institute in London, and the new Law Courts at Birmingham. In these buildings the peculiar features of the style are visible—viz. large windows, divided by plain mullions, and a mixture of classic details and Gothic forms. The style adapts itself well to villas and smaller structures, in which the curved gables of the dormers form prominent features.

In Germany, Russia, and every country of Europe the Renaissance came to prevail in a manner similar to that above described in other countries. The picturesque castle of Heidelberg is an early example, and the Zwinger and Japanese palace at Dresden are edifices of the beginning of the 18th century. In the domestic buildings of Nuremberg, Dresden, and other towns of the north of Germany many instances occur of the picturesque application of classic detail to the old Gothic outlines. One of the most striking examples of the revival of classic art occurred in Bavaria during the first half of the 19th century, under the auspices of King Louis. He caused all the buildings he had seen and admired in his travels to be reproduced in Bavaria. Thus, the royal palace at Munich is the Pitti Palace of Florence on a small scale; St Mark's at Venice is imitated in the Byzantine Chapel Royal; and the Walhalla, on the banks of the Danube, is an exact copy (externally) of the Parthenon. The finest buildings of Munich are the Picture-gallery and Sculpture-gallery by Klenze, both well adapted to their purpose, and good adaptations of Italian and Grecian architecture. In Vienna and Berlin there are many examples of the revived Classic and Gothic styles, but the Germans have always understood the former better than the latter. The

Fig. 3.—Park Front of Castle Howard.

and, although it is perfectly useless, the light and convenience of the house are invariably sacrificed for it.

The further study of the buildings of Greece and Rome led, in the beginning of the 19th century, to the fashion of reproducing them more literally. All important public buildings were now required to be absolute copies of ancient buildings, or parts of them, or to look like such, and then the architect had to work out the accommodation as best he might. St Pancras' Church in London is a good example. It is made up of portions from nearly

Fig. 4.—Portion of Façade of Bridgewater House.

every temple in Greece. Many really successful buildings, such as St George's Hall, Liverpool, the High School and Royal Institution (Royal Scottish Academy) in Edinburgh, have been erected in this style; but they owe their effect not to their being designs well adapted to their requirements, but to the fact that they are copies from the finest buildings of antiquity. We have thus two different styles included under the head of Renaissance—viz. one in which the classic elements are subordinated to the Gothic dispositions, as is now generally understood by the expression 'Renaissance;' and the other in which the classic elements distinctly predominate, commonly known as 'Classic.'

Sir Charles Barry was the first to break away from this thralldom, and to return to the true

museums at Berlin, and many of the theatres of Germany, are good examples of classic buildings. The domestic architecture of Berlin is well worthy of notice, many of the dwelling-houses being quite equal in design to those of Paris. Of the other countries of Europe the only one which deserves remark for its Renaissance buildings is Russia. St Petersburg is of all the cities of Europe the one which best merits the title of a city of palaces. From the date at which the city was founded, these are necessarily all Renaissance in character. They are nearly all the works of German or Italian architects, and are unfortunately, for the most part, in the coldest and worst style. The ornaments of the palaces are chiefly pilasters running through two stories, with broken entablatures, &c., and ornaments of the flimsiest rococo. The New Museum, by Klenze, is, however, a marked exception. In America nearly all the new buildings of importance are carried out in the Renaissance style. Many of these are of great size and striking design. The town-hall of Boston may be referred to as one of the most imposing and effective. Another conspicuous example is the town-hall of Philadelphia (q.v.).

Along with architecture, during the period of the Renaissance Painting and Sculpture and all the other arts took their models from the classic remains which were so carefully sought for and studied. All ornamental work, such as carving, jewellery, and metal-work of every kind, followed in the same track. Mediaeval niches and pinnacles gave place to the columns and entablatures of the classic styles, and the saints of the middle ages yielded to the gods and goddesses of ancient Rome.

See the general historical works of Gregorovius, Guizot, Hallam, Lacroix, Lecky, Villari, &c., the relevant chapters in the standard histories of the different countries, especially in that of Italy, and in the *Cambridge Medieval History and Camb. Modern Hist.*; also Voigt, *Die Wiederbelebung des klassischen Altertums* (1859); 3d ed. 1893); Burckhardt, *Kultur der Renaissance in Italien* (1890); 8th ed. 1901); Pater, *The Renaissance* (1873); Palastro, *La Renaissance en France* (1879-95); Gebhart, *Les origines de la Renaissance en Italie* (1879); J. Renaix, a town in the Belgian province of East Flanders, 25 miles by rail S. by W. of Ghent, carries on dyeing, and manufactures cotton and woollen fabrics; pop. 22,000.

Renan, ERNEST, was born at Tréguier, in the department of Côtes-du-Nord (Brittany), on the 27th February 1823, a Breton by his father's ancestry, a Gascon by his mother's. The centre of the life of Tréguier (originally a monastic village) is its minster, and to the atmosphere of the place Renan attributed in large measure his early bent to those studies which he unceasingly

pursued for more than half a century. His father, who was a sailor, died while he was still a child, leaving his widow in straitened circumstances, with the care of one daughter and two sons. To his mother and sister Renan owed a special debt, which he expressly acknowledged in his *Souvenirs d'Enfance*. The young Renan gave early promise of distinction, and in 1836 he was one of the lads chosen by the Abbé Dupanloup for a place in the Catholic seminary of St Nicolas du Chardonnet, in Paris, conducted by himself on methods entirely his own, his one aim to turn out priests with the accomplishments and temper of mind that would render them effective men of the world. After three years at St Nicolas he had two years of philosophy at Issy, a branch of the great seminary of St Sulpice. Descartes adapted to Catholic orthodoxy, and the Scottish philosophy as taught by Reid, were the main subjects of study. At the conclusion of his course at Issy he was in all things, personal habits and temper of thought, a docile son of the church; though one of his teachers had already divined the essential tendency of his mind, and had plainly told him 'that he was not a Christian.' At St Sulpice, however, his attention was mainly turned to the study of Hebrew, and to this study, of his own accord, he added that of German. As the result of these combined studies the traditional construction of Christianity became impossible for him. Quitting St Sulpice in 1845, he abandoned all thoughts of the church as a profession. At this crisis his sister Henrietta proved his invaluable friend and comfort. In 1848 he became *agregé de philosophie*, and two years later was appointed to a post in the department of manuscripts in the Bibliothèque Nationale in Paris. Successive *mémoires* made his name known in connection with Oriental studies, and in 1860 he was made one of a commission sent by the French government to study the remains of Phœnician civilisation. In 1861 he was chosen professor of Hebrew in the Collège de France. The emperor, inspired by the clerical party, refused to ratify his appointment, and it was not till after the fall of the imperial government (November 1870) that he was actually established in the chair. He travelled considerably in Italy, in Scandinavia, and the East in connection with special departments of research, and in 1878 was chosen member of the French Academy. Renan married a niece of the painter Ary Scheffer.

Of the long series of Renan's works, which by their combined learning and literary power made him the first man of letters in Europe, we can here note only those which call for special mention in a summary account of his career. His work as an author began with a paper *Sur les Langues Sémitiques* (1847), afterwards developed into his *Histoire Générale des Langues Sémitiques* (1854). In his *Acerbois et L'Acerboisme* (1852) he gave one proof among many others of his familiarity with the life and thought of the middle ages. He wrote frequent essays, afterwards collected in his *Études d'Histoire Religieuse* (1856) and *Essais de Morale et de Critique* (1859), which arrested wide attention by their grace of style and originality of suggestion. His European reputation, however, dates only from the publication of the *Vie de Jésus* (1863), 'one of the events of the century.' With the *Vie de Jésus* also began what its author regarded as the special work of his life, the *Histoire des Origines du Christianisme*. In Renan's conception the history of Christianity, in the true sense of the term, is possible only from the close of the 2d century after Christ. Previous to that period materials do not exist for an adequate narrative based on data that justify a dogmatic construction of the development of Christianity. The tracing

of Christian origins, therefore, must be a work essentially tentative, and one that, justifying conjecture, calls for the finest critical faculty in him who attempts it. It was with this conception of his task that Renan wrote the series, the labour of nearly thirty years, in which he embodied his construction of the evolution of the Christian religion and theology. Of all the volumes none excited the extraordinary interest of the first. In the *Vie de Jésus* the combined weakness and strength of Renan's method were exaggerated to caricature on a subject of supreme and universal interest, and one, moreover, which even from the boldest critics had hitherto exacted the tacit admission of its special place in the heart of humanity. Few readers, even in France, received it without large reserves on the score of good taste and right feeling, while in Britain its preciosity of sentiment and effeminate exquisiteness of manner jarred even on those who were at one with the writer in his general point of view. Of the volumes that followed the *Vie de Jésus*, that on St Paul and that entitled *Marc Aurèle et la Fin du Monde Antique* are specially noteworthy, the one as assigning to the apostle a much inferior place in the history of the Christian church to that which Protestants at least have assigned him, the other for its brilliant delineation of the last stages in the life of paganism. In completion of the task he had set before him, Renan undertook what, as he himself said, should have been the natural beginning of his work, the history of the people of Israel.

Besides this main product of his genius and industry, Renan from time to time published other volumes, some, such as *Questions Contemporaines*, and *La Réforme Intellectuelle et Morale*, on the current questions of the day, and others, such as the *Dialogues Philosophiques* and *Drames Philosophiques*, on the profounder questions of human life and destiny. In 1883 appeared *Souvenirs d'Enfance*, in which he traced in his most delicate vein the influences that worked in him during his childhood and early youth. As a supplement, Renan published *L'Avenir de la Science* (1890), conceived and written in 1848. Taken with the preface of 1890, this book throws a vivid light at once on the history of its author's opinions and on that double nature he inherited from his Celtic and Gascon ancestry. In his earlier work sentiment is often strained beyond the limit of virile feeling; his later writings often reveal the Gascon by unseasonable persiflage and epicurean suggestion. He died 21 October 1892, and was buried in the Panthéon.

Renan's *Histoire des Origines du Christianisme* consists of the following volumes: *Vie de Jésus* (1863), *Les Apôtres* (1866), *Saint Paul* (1867), *L'Antéchrist* (1873), *Les Évangiles et la Seconde Génération Chrétienne* (1877), *L'Église Chrétienne* (1878), *Marc-Aurèle et la Fin du Monde Antique* (1880), *Index général* (1883); its great complement, *Histoire du Peuple d'Israël* (5 vols. 1887-1894). Other writings are: *Le Livre de Job* (1859); *Le Cantique des Cantiques* (1860); *L'Écléaste* (1882); *Histoire Générale des Langues Sémitiques* (1854); *Mission de Phénicie* (1865-74); *Études d'Histoire Religieuse* (1856); *Nouvelles Études d'Histoire Religieuse* (1884); *Averroès et l'Averroïsme* (1852); *Essais de Morale et de Critique* (1859); *Mélange d'Histoire et de Voyages* (1878); *Questions Contemporaines* (1868); *La Réforme Intellectuelle et Morale* (1871); *De l'Origine du Langage* (1863); *Dialogues Philosophiques* (1876); *Drames Philosophiques*, including *Culiban*, *L'Eau de Jouvence*, *Le Prêtre de Némé*, *L'Abbesse de Jouarre* (1888); *Souvenirs d'Enfance et de Jeunesse* (1883); *Discours et Conférences* (1887); *L'Avenir de la Science* (1890); the Hibbert Lectures (1880), delivered in London, on *The Influence of the Insti-*

and Sister, 1896); *Ernest Renan-Henriette Renan: Nouvelles Lettres intimes* (1923).

For critical estimates, see Sainte-Beuve, *Nouveaux Lundis* (tome ii.); Schérer, *Études sur la Littérature Contemporaine* (tome viii.); G. Monod, *Les Maîtres de l'Histoire* (1895). See also Grant Duff's *In Memoriam* (1893); Lives by Séailles (1895), Mary Duclaux (1897), W. Barry (1905); R. Allier, *La Philosophie d'E. Renan* (1906); Lookroy's *Au Hasard de la Vie* (1913); Guéard's *French Prophets of Yesterday* (1913); L. F. Mott's *Study* (1921), and Pommier's (1923); also Girard and Monod, *Bibliographie* (1923).

Rendsburg, a town of Sleswick-Holstein, stands on the Kiel Canal, 19 miles W. of Kiel, and has manufactures of cotton, machinery, and chemicals; pop. 16,000.

René I., surnamed 'the Good,' titular King of Naples and Sicily, the son of Louis II., Duke of Anjou and Count of Provence, was born in 1409 at Angers. He failed in his efforts to make good his claim to the crown of Naples, gave his daughter in marriage to Henry VI. of England (1445), and ultimately devoted himself to Provençal poetry and agriculture at Aix in Provence, where he died regretted in 1480. See ANJOU, and a monograph by Edgumbe Staley (1913).

Renfrew, an ancient royal burgh, the county town of Renfrewshire, stands on the south bank of the Clyde, 6 miles below Glasgow. Its first charter dates from 1313, and Robert III. made it a royal burgh in 1397, but it was a burgh at least as early as the reign of David I. (1124-53). A knoll called Castlehill commemorates the site of Renfrew castle, the original seat of the royal house of Stewart. Anciently the chief port on the Clyde, it has still a small harbour. The principal industries are shipbuilding, water-tube boiler-making, and engineering. For parliamentary purposes up to 1918, it formed one of the Kilmarnock group of burghs. Pop. (1841) 2013; (1891) 6777; (1921) 14,161.

Renfrewshire, a county in the south-west of Scotland, bounded on the N. by the river and firth of Clyde, on the E. by Lanarkshire, and on the S. and W. by Ayrshire. Though only twenty-eighth of the Scottish counties in size, it stands fifth in population. It is 31 miles long by 13 broad, and contains about 240 sq. m. or 151,431 acres, including water and foreshore. Pop. (1801) 78,056; (1851) 161,091; (1881) 263,374; (1911) 314,374; (1921) 298,904. The surface is irregular; besides the low lands fringing the Clyde, there are three principal valleys, those of the Gryfe, the Black Cart, and the White Cart, with upland pastures and ranges of hills, the highest point being the Hill of Stake (1711 feet) on the borders of Ayrshire.

Agriculture and the breeding of horses and cattle are carried on with success; dairy-farming is largely practised, owing to the proximity of large towns. Rather less than two-thirds of the whole extent is arable, mainly in pasture or grass crops. The minerals are coal, iron-stone, shale, and lime. Besides mining and agriculture, numerous industries flourish in various parts of the county, the principal being the manufacture of thread, cotton, and chemicals, print and bleach works, shipbuilding, engineering, distilling, and sugar-refining. Renfrewshire is well supplied with roads and railways, and has two considerable ports—Greenock and Port-Glasgow. It is divided for administrative purposes into two wards, Upper and Lower, with sheriff's-substitute at Paisley and Greenock. There are two parliamentary divisions, eastern and western, each returning one member. From time to time parts of Renfrewshire have been detached and added to Glasgow. The chief towns, besides those mentioned, are Renfrew, the county town

and only royal burgh, Johnstone, and Barrhead. Renfrewshire, or at least the western portion, was anciently called Strathgryfe, and it was the chief patrimony of the house of Stewart. In 1404, not long after the accession of that family to the crown, the title of Baron of Renfrew (still borne by the Prince of Wales) was conferred by Robert III. on his son James; and about the same time Renfrew was disjoined from the sheriffdom of Lanark and made a separate county.

See county histories by Crawford (1716), and Metcalfe (1905).

Reni, GUIDO. See GUIDO.

Renner, KARL (b. 1870), Austrian politician, studied law at Vienna, and from 1907 to 1918 sat in the imperial parliament as a social democrat. He became the first chancellor of the Austrian republic, remaining in office 1918-20. He headed the Austrian Peace Delegation at St Germain in 1919, and in 1920 worked for a *rapprochement* with Czechoslovakia. He has published various works on political and international questions, as well as the national song of the republic, 'Deutschösterreich du herrliches Land.'

Rennes (the *Condate* of the Redones), the capital formerly of the province of Brittany, and now of the department of Ille-et-Vilaine, is situated at the confluence of those two rivers, 234 miles WSW. of Paris and 51 SSE. of St Malo. A seven days' fire in 1720 destroyed nearly 4000 houses, and the ancient walls have been superseded by pleasant promenades, so that the place wears a modern aspect. Four bridges connect the upper or new town and the lower or old town, and the most noteworthy of the public buildings are the cathedral, finished in 1844, and Italian in style; Notre Dame, with its dome surmounted by a huge image of the Virgin; the archbishop's palace (1672); the stately Palais de Justice (1618-54); the university buildings (1855), with a picture-gallery; the theatre (1835); the Hôtel de Ville, with a public library; and the Lycée. As the focus of main and branch lines of railway between Paris and the north-west of France, and commanding good river and canal navigation, Rennes is favourably situated for commerce; and, in addition to the transport of the abundant farm-produce of the neighbouring districts, it carries on a considerable trade in its own manufactures, which include printing, weaving and tanning, &c. Pop. (1872) 48,658; (1921) 82,241.

Rennet is the enzyme which causes the curdling of milk, and occurs in the gastric secretion of all mammals. It is also found in other animals, is secreted by some bacteria and occurs in many seeds, some of which (e.g. *Withania coagulans*) are used for its commercial preparation. It is usually obtained by digesting the dried rennet stomach (the abomasum or fourth compartment) of the calf with water containing 5 per cent. of salt or a little boric acid. The extract is either sold as such or is evaporated at a low temperature in a vacuum, yielding a powder. Rennet is largely used in cheese making. When it is added to milk the caseinogen of the milk is converted into casein and this separates out as a curd, carrying down with it the fat globules of the milk. The curd gradually contracts, expelling the clear whey, which is almost free from fat and contains the milk sugar and lactalbumin. Rennet acts most rapidly at about blood heat (98° F., 37° C.) and only very slowly curdles milk which has been boiled. Rennet preparations have been obtained of which one part by weight was capable of coagulating one million parts of milk. See DIGESTION, FERMENTATION.

Rennet. See APPLE.

Rennie, JOHN, civil engineer, was born at the farm of Phantassie, near East Linton, East Lothian, 7th June 1761. After being for some time a workman in the employment of Andrew Meikle, inventor of a Threshing-mill (q.v.), he attended the lectures of Robison and Black at Edinburgh University. He visited (1784) the works of Messrs Boulton and Watt at Soho, near Birmingham, and was immediately taken into employment by that eminent firm. Here his mechanical genius soon displayed itself; and so highly did Watt esteem Rennie that he gave him, in 1789, the sole direction of the construction and fitting-up of the machinery of the Albion Mills, London; and the ingenious improvements effected in the connecting wheel-work were so striking that Rennie at once rose into general notice, and abundance of mill-work now flowed in upon him. To this branch of engineering he added, about 1799, the construction of bridges, in which his pre-eminent talent and ingenuity displayed themselves. The chief of his bridges were those of Kelso (1803), Leeds, Musselburgh, Newton-Stewart, Boston, and New Galloway, with the Waterloo Bridge (see LONDON). Another of his works is Southwark Bridge; he also drew the plan for the London Bridge, which, however, was not commenced till after his death. He superintended the execution of the Grand Western Canal in Somerset, the Polbrook Canal in Cornwall, the canal between Arundel and Portsmouth, and, chief of all, the Kennet and Avon Canal between Newbury and Bath; he drained a large tract of marsh land in the Lincoln Fens. The London Docks, the East and West India Docks at Blackwall, the Hull Docks, the Prince's Dock at Liverpool, and docks at Dublin, Greenock, and Leith were designed by him, and wholly or partially executed under his superintendence. He planned many improvements on harbours and on the dockyards at Portsmouth, Chatham, Sheerness, and Plymouth; excelling at the last-mentioned port the most remarkable of all his naval works, the celebrated Breakwater (q.v.). He made great improvements in the diving-bell. He died 4th October 1821, and was buried in St Paul's Cathedral. A striking characteristic of his works is the remarkable combination in them of beauty and durability; and though they were frequently objected to on the ground of costliness, yet in the end their lasting qualities more than compensated for this. In person Rennie was of extraordinary stature and herculean strength. See Smiles's *Lives of the Engineers* (1874).

GEORGE KENNIE (1791-1866), eldest son of the preceding, was born in Surrey, educated at Edinburgh University, was superintendent of the machinery of the Mint, and aided his father. With his brother John he carried on an immense business in shipbuilding, railways, bridges, harbours, docks, machinery, and marine engines.—SIR JOHN KENNIE (1794-1874), knighted in 1831 on the completion of London Bridge, was engineer to the Admiralty. See his *Autobiography* (1875). He wrote on harbours.

Reno, the largest town in Nevada, 32 miles NW. of the capital, Carson City. It is a manufacturing centre, and is the seat of the State University of Nevada. Pop. 12,000.

Renoir, AUGUSTE (1841-1919), French painter of the Impressionist school, born at Limoges, spent most of his early life in Paris, becoming friends with Sisley and Monet, and began painting, choosing everyday subjects and experimenting with light and colour. Throughout all his life Renoir expressed his fondness for the 'sensual' qualities in colour, always using the full brush, but about 1880 he came under the influence of Ingres, and on a

visit to Italy was much struck by the simple modelling of Raphael. From this period date most of his nudes, treated with a hand, glossy brilliance. In 1890 Renoir left Paris for Provence, and turned his attention more to landscapes. His work is chiefly characterised by its opulent colouring, applied in transparent layers. See IMPRESSIONISM, studies by Fossa (1925) and Vollard (trans. 1926).

Renouvier, CHARLES (1815–1903), French philosopher, was born at Montpellier and educated at the Ecole Polytechnique, Paris. His chief works are *La Science de la Morale* (1869), *Uchronie* (1876), *La Philosophie analytique de l'histoire* (1896–97), *Le Personalisme* (1903), and *Critique de la doctrine de Kant* (1906). Renouvier's idealistic 'neo-criticism' continues in modified form the philosophy of Kant, and lays great stress on the liberty of the individual, and on personal experience. See the studies by Séailles (1905) and Arnal (1907).

Rent, in common speech, is money paid for the use of land or houses. In political economy it usually means money paid for the use of land; and it is in this reference that the theories and discussions of economists regarding rent have arisen. Economists have generally held it to be the great merit of Ricardo that he elucidated the true theory of rent. Anderson, Malthus, and West had indeed enunciated it before, but the classical statement of it (fully developed in his *Principles of Political Economy*, 1817) came from Ricardo. According to that theory the amount of rent paid represents the excess of the price of the produce of the land over the cost of production on that land. The cost of production includes the usual wages paid to the labourer, and the usual interest on the capital applied to the land, as well as remuneration of management. In other words, after the labourer has been paid the usual wages and the farmer has received the usual return for his capital and trouble from the produce of the land, the remainder is rent.

It will be seen therefore that the amount of the rent depends on the price obtained for the produce. Rising prices for agricultural produce mean rising rents. And in this, as in other departments, prices depend on the relation of demand to the supply. A rapidly increasing demand, or in other words, a rapidly growing population, and a supply that cannot nearly keep pace with it will lead to a great rise in prices. Such was the condition of England at the end of the 18th century and the beginning of the 19th, when a rapidly growing population had to depend almost solely on the home market. At such a time there was a great rise in rents. During the last generation the population has increased with a similar rapidity, yet, owing to free trade, the enormous development of the means of transport, and the opening up of vast agricultural lands in America and the colonies for the supply of the home market, prices have fallen and also rents. The demand has increased, but the supply has increased vastly more, and in spite of the growing population rents have fallen. The general truth however remains that rent depends on prices, and not prices on rent. Or, to use the Ricardian formula, which, however, is not a satisfactory expression of the fact, rent is not an element in the price of corn.

After having been much overrated as a discovery in political economy, the Ricardian theory of rent is now in many quarters unduly depreciated. It still remains generally valid under the conditions contemplated by its exponent. Those conditions are a system of land-holding by private owners who do not cultivate their land, capitalist farmers, and free labourers; the relation of the three classes

to each other being determined by competition. In other words, the economists who have worked out the theory have had in view England, and other countries in so far as they are similarly circumstanced as England. But even in England there are many things which greatly modify the operation of the principle—the influence of custom, the natural conservatism of all classes, local attachment on the part of the farmer and labourer, &c. Very important also is the fact that many of the landlords have regard to social and political considerations, as well as to reasons of fairness and equity in fixing their rents. It must, moreover, be remembered that a disturbance in agricultural prices, such as that caused by the introduction into European markets of the enormous supplies from America, may have rendered the Ricardian theory ludicrously inapplicable to the rents actually paid, particularly under long leases. Under these circumstances rent was often paid not out of the surplus of the farmer's profits, but out of his capital. The Ricardian theory of rent therefore formulates a tendency which, even under the conditions contemplated, accords with facts only in a rough and general way.

When we consider economic history and the existing economic conditions of the world we may perceive how limited in scope the Ricardian theory of rent has been. In many countries custom has decided, and still decides, the rent paid for land. In very many countries it has not been either competition or custom that has regulated rent, but the owner has wrung from the cultivator all that he could. The only limit to the exactions of the owner has been his own pleasure or caprice or the endurance of the cultivator. In countries, however, where the state is the owner of the land rent may more correctly be regarded as a tax.

The rent paid for land occupied by towns and that paid for mines are in some important respects different from the rent of agricultural land. The rent paid for land in towns is much more directly influenced by the increase of population and the growth of prosperity. Inasmuch as the owner receives great advantages from such causes while contributing little or nothing, economists of standing maintain that such land should be under municipal ownership and control. The rent paid for mines is materially affected by the fact that mines become exhausted, while the agricultural properties of the soil are permanent in the main. As regards rent generally, it should be repeated that economic formulas are of comparatively little value. The main thing is a thorough knowledge of the facts and conditions, which vary continually according to the time and country with which we are concerned. For other aspects of rent, see also LAND LAWS, LANDLORD AND TENANT.

Renton, a town of Dumfriesshire, on the right bank of the Leven, 2 miles N. by W. of Dumfries. Founded in 1782, it has a Tuscan column (1774) to the memory of the novelist Smollett, who was born close by, and it carries on calico-printing, dyeing, and bleaching. Population 5000.

Renwick, JAMES, the last of the martyrs of the Covenant, was born at Moniaive, Dumfriesshire, 15th February 1662. He attended Edinburgh University with a view to the ministry, but was denied his degree, as he refused the oath of allegiance; and, after witnessing the deaths of Cargill and others of the martyrs, he resolved to embrace the cause for which they suffered. He was chosen by the 'Societies,' as the bands of men devoted to the Covenant were called, to proceed to Holland to complete his studies in 1682, was ordained at Groningen in 1683, and at once proceeded to Scot-

land, where his first sermon was preached at Darnead Muir in the same year. His life was now exposed to great hazards; he was obliged to move from place to place, and was often reduced to destitution. In 1684 he published his *Apologetic Declaration*, for which he was outlawed. When James II. came to the throne in 1685 Renwick with 200 men went to Sanguhar, and published a declaration rejecting him. A reward of £100 was offered for his capture, he was hunted from place to place, and made many hairbreadth escapes, but was at last captured in Edinburgh. He was condemned and executed, 17th February 1688.

See Shield's *Life, Renwick's Chosen Collection of Sermons*, &c. (1777), Simpson's *Life of Renwick* (1843).

Repairs is the legal as well as popular term to denote the repairs done to a house or tenement by a tenant or landlord during the currency of the lease. In England the burden of repairs is at common law thrown on the tenant, so that, unless the lease expressly says that the landlord is to do the repairs, the tenant will be bound to use the premises fairly and to keep house property wind and water tight. Usually the lease states who is to do the repairs. In the lease of farms the tenant is bound only to keep the house in repair, and not the out-buildings, though he is bound to keep the fences in repair. If the landlord is bound to do the repairs, and fails to do them, the tenant is not entitled to quit the premises on that account, though he will be entitled to sue the landlord for damage caused by the want of repairs. In Scotland the landlord is bound at common law to put the premises into tenable repair at the commencement of the lease. The tenant is then bound to keep them in ordinary repair, but not to keep them in repair where some hurricane or extraordinary cause has done injury. In the United States the laws of the states vary; in several states it is enacted that a general promise to repair shall not bind the tenant to rebuild in case of destruction by fire.

Repentance, STOOL OF. See STOOL OF REPENTANCE.

Replevin, in English law, is a form of action by which goods which have been seized under a distress are taken back (security being given to the amount for which the goods were distrained), and the action of replevin commenced, to try the legality of the seizure.

Reporting, a notable department of journalism, has already been incidentally discussed at NEWSPAPER; the methods by which, as a rule, it is practicable are dealt with at SHORTHAND. An account of the history of parliamentary reporting, in some respects the most important, may first be given here.

Accounts of single speeches, and, at times, of entire debates in the English parliament, have come down from a very early period. The earlier volumes of the Journals of the House of Commons contain short notes of speeches; the later volumes record nothing but the votes and proceedings. Sir Symonds d'Eves edited the *Journals of Queen Elizabeth's Parliaments*; and the Commons' Journals contain notes of speeches in the parliaments of James I. Rushworth, assistant-clerk in the Long Parliament, 1640, took down in a species of shorthand any speech of importance; and his account of *Remarkable Proceedings in Five Parliaments* forms one of the most valuable portions of his *Historical Collections*. During the reign of William III. a member now and then sent a copy of his speech to the newspapers, for printing which, however, they were sometimes called to account. In the reign of Queen Anne a monthly pamphlet, called the *Politi-*

cal State, gave an outline of the debates in parliament. In the reign of George I. the *Historical Register*, published annually, professed to give reports of parliamentary speeches. The *Gentleman's Magazine* began a monthly publication of the debates, the number for August 1735 containing a report of the debate in the House of Lords on the previous 23d January. Cave, the publisher, continued the practice in succeeding numbers. There was, however, no publication of the debates during the sitting of the Houses; parliament was always prorogued before anything said in the course of the session was given in the magazine. At first the names of the speakers were cautiously indicated by the first and last letter only, and in many cases the speaker's name was wholly omitted. Growing bolder by degrees, Cave printed the names at length. The House of Commons soon took alarm. The publication of the debates of either House had been repeatedly declared to be a high breach of privilege—as by the Commons in 1588 and by the Lords in 1698; and in 1738 Speaker Onslow called the attention of the House to the breach of its standing orders by Cave and others. The result was another thundering resolution against the publication of debates 'either while parliament is sitting or during the recess,' and a threat to proceed against offenders with the 'utmost severity.' The reports, notwithstanding, still appeared, but under the disguise of 'Debates in the Senate of Lilliput,' in the *Gentleman's Magazine*; and 'Debates in the Political Club,' in the *London Magazine*. Dr Samuel Johnson was employed by Cave in the composition of his parliamentary debates, and the reports from 1740 to 1743 are held to have been entirely prepared by him. It was not till thirty years later that the parliamentary debates descended from the magazines to the newspapers. The latter had, however, for some time resolved to report the debates, and they took advantage of the popular excitement arising out of the Luttrell-Wilkes election for Middlesex to try the right of the House to interdict the publication of its proceedings.

The ever-memorable contest between parliament and the press began at the close of the year 1770. The House of Commons followed up another solemn threat by prompt action; and the Lord Mayor of London and Alderman Oliver were sent to the Tower for refusing to arrest some printers of reports on the warrant of the Speaker, John Wilkes taking an active share in the controversy. The city of London loudly protested against the arbitrary proceedings of the House, and the whole country responded to the appeal. The power of parliament to imprison ceases at the end of the current session, and on the day of prorogation, 23d July, the Lord Mayor and Alderman Oliver marched out of the Tower in triumph, and at night the city was illuminated. Next session the House of Commons tacitly acknowledged itself beaten. The printers defied the House, continued to publish their proceedings, and slept, notwithstanding, secure in their beds. In a short time the House of Lords also conceded the point, and the victory was complete. It still remained for many years in the power of any member of the House of Commons, by the historic formula, 'Mr Speaker, I spy strangers,' to cause the exclusion of the public and the reporters from the House. Since 1875, however, a direct resolution of the House has been necessary. Secret sessions were held on six occasions during the Great War, 1914-18, under this procedure, reinforced by stringent Defence of the Realm Act regulations.

The old machinery of parliamentary reporting was susceptible of immense improvement. One of the Woodfalls (a brother of the Woodfall of Junius)

had so retentive a memory that when editor of the *Morning Chronicle* he used to listen to a debate in the gallery, and write it out next day, the taking of notes being at that time forbidden. His successor established a corps of parliamentary reporters to attend the debates of both Houses every night in succession. He thus brought out the night's debate on the following morning, anticipating his rivals by ten or twelve hours. The improvement in the reports of the debates from the period of the American Revolution until the year 1815 was but gradual. At the close of the French war, however, the publication of parliamentary debates became an object of national importance, and in the course of a few years assumed its present full, detailed, and accurate character. Increased facilities for the discharge of their important and arduous duties were from time to time given to the reporters, who till then had no means of entering the Strangers' Gallery except those which were common to the public generally. Amongst the professional parliamentary reporters of this period Charles Dickens was conspicuous. He was at work for the *Morning Chronicle* in 1834, and was one of the best reporters of his time.

Not a few distinguished lawyers, also, like Lord Mervill, Sir Edward Clarke, and Lord Hewart, reported parliamentary debates in their earlier days.

Exclusive accommodation for reporters was provided in the House of Lords in 1831, although, it is curious to note, the order prohibiting the reporting of debates was then still in force. The Press Gallery in the House of Commons dates from 19th February 1835. Modern organisation, and the use of telephone and private telegraph wires by the leading newspapers and press agencies, enables news of any important announcement in parliament, or decision of the legislature, to be despatched within a minute or two to all parts of the country, while the substance of interesting speeches is often in the columns of the evening newspapers almost before the orator has resumed his seat.

Cobbett's, afterwards Hansard's, parliamentary debates were originally compiled from outside sources, and a staff of reporters was not introduced until 1878. Since 1909, however, official reports of the proceedings in both Houses of Parliament have been published under government control.

Parliamentary sketch-writing was introduced in the 'fifties as a feature of the weekly press, and found its way, about twenty years later, into the daily newspapers, generally as an introduction to the more formal report. Distinguished writers like Sir Henry Lucy and H. W. Massingham raised this form of journalism to the level of literature.

Another comparatively late development is lobbying, a select number of press representatives being admitted to the members' lobby for the collection of political news and opinions.

(See *The Reporters' Gallery*, by Michael MacDonagh; also the introduction to *Pillars of the State*, by Herbert Sidebotham.)

A further important branch of reporting is that relating to judicial proceedings, civil and criminal, and this, in the higher courts particularly, calls for ability, experience, and always the utmost accuracy. A mistake may be fraught with grave consequences, as some newspapers have found to their cost, by reason of expensive actions against them for libel. Proceedings in open court, i.e. any hearing to which the public are admitted, can be reported in the press provided they are relevant to the case before the court, and that the account is fair and accurate, subject, however, to some prohibition as to obscene matter, and also to a discretion by the judge in certain instances. Much attention is given by newspapers to law reports, and an action

or trial arousing widespread interest obtains many columns of space.

The reporting of sport and athletic prowess, more especially horse-racing, football, cricket, and golf, demands quickness of eye, knowledge, and

almost incredible rapidity the results of racing and other sporting events. By means of 'tick-tacking'—a system of signalling by the hands and arms—an observer who watches the race through glasses from some vantage-point overlooking the course communicates with a colleague stationed at the nearest available telephone; thereafter trunk telephones, private telegraph wires, and tape instruments combine to spread the news with such speed that very often the result has reached every large town in the British Isles in less than a minute of the first horse passing the post.

Nowadays the reporter makes very great use of the telephone, local and trunk, for transmitting news matter to his office. In the case of long or verbatim reports of important political speeches, conferences, and trials he takes a prescribed 'turn,' varying in length according to the exigencies of the case and the size of the staff engaged, and then hurries to the nearest telephone to dictate direct from his shorthand notes to colleagues in silence boxes in the office of the news agency or journal, which may be several hundreds of miles away. This method has largely superseded the transcription by the reporter himself of his notes and the despatch of the report to the post-office for telegraphic purposes.

The interests of reporters are in charge of two bodies—the Institute of Journalists (a chartered organisation embodying employers and employed) and the National Union of Journalists, which is avowedly a trade union of employees. The qualifications, status, and remuneration of reporters have considerably improved in recent years.

Repoussé (Fr.). This term is applied to a peculiar method of ornamenting metal which resembles Embossing (q.v.). Briefly stated, it is metal-work formed in relief by striking the sheet, usually a thin one, from behind with a hammer or punch, the rough forms so produced being afterwards chased or otherwise finished. After the parts which require to be convex are 'raised' from the back or inside of any object, such as a vase or flat dish, it is either filled with or placed on a bed of pitch and then worked upon the face with small punches, and afterwards with chasing, engraving, and other tools. Stamping produces work somewhat similar in general appearance, but of a much more mechanical nature, since the die used determines exactly the pattern, and no variety is obtained. See DIE SINKING. Some kinds of hammered iron, again, such as open ornamental gates and grilles, are rather examples of forging than of repoussé. Among the best existing pieces of ancient Greek bronze sculpture some have been beaten up (not cast), and are therefore of the nature of repoussé work. A number of the famous artistic productions—notably those of the 16th century—referred to under the head METAL-WORK are executed in repoussé. This art, by which, in the hands of a master, work can be executed with a delicacy, softness, and beauty unattainable by any other process, was revived (in a true artistic sense) in France about the middle of the 19th century. Some of the finest modern works in repoussé have been executed by Antoine Vechte and Morel Ladeuil. One of the largest objects ever produced in repoussé in England is the Elcho Volunteer Challenge Shield. It is of iron, 6 feet high, and was designed by F. Watts, R.A.

Elaborate work in repoussé is necessarily very costly, especially if the metal employed is hard, such as iron, copper, or silver, which is usually the case when important designs are to be executed. But the process is also applied in Birmingham to decorate comparatively cheap articles in Britannia metal, which is soft and easily worked.

Representation, in politics, is the function performed by the elected members of legislative and administrative bodies. Ancient democracies were usually constituted on the principle of government by the whole body of citizens; at Athens, for example, all important questions were decided by the vote of the Ecclesia. In England, as in many other countries, the freemen of townships and small districts elected their own officers and managed their own affairs; the shire-moot of early times was attended by the reeve and four men from each township; it was, in fact, a representative assembly, properly so called. When the smaller kingdoms were united under one head the change was not at first favourable to popular government; it was impossible in those days to bring together representatives from a wide area; and the conduct of national affairs fell into the hands of the king and his councillors and the great men of the realm. But feudal custom required that a superior should consult his vassals, or some of them, before levying any exceptional aid; under the influence of this idea courts or assemblies of a more or less representative character were formed throughout western Europe. In England the high court of Parliament (q.v.) was organised on a feudal basis, like the neighbouring parliament of Scotland; but, as early as the 13th century, Clergy, Lords, and Commons sent representatives to parliament. For subsequent history in England, see PARLIAMENT. The mediæval Italian republics had aristocratic institutions, and the States-general (q.v.) in France had no legislative power. It was not until the 17th and 18th centuries that the subject of representation became at all prominent with the establishment of the Dutch republic (but see STADTHOUDER), the Civil War in England and the discussions of the philosophers, Locke, Hobbes, Hume, Rousseau, the Encyclopedists, whose theories of the sovereignty and will of the people were put to such a startling test in the French revolution of 1789. The European history of the 19th century and of the first decades of the 20th can almost be summarised in the struggle between the parties of liberalism and reaction. In many cases the immediate results of the 1830 and 1848 revolutions were not lasting, but as a consequence of the Great War, 1914-18, several states were established on the principles of self-government and self-determination (see REPUBLIC). This scheme of parliamentary institutions, by which a nation determines its own destiny, being ruled by elected representatives in the name of the whole body of citizens, has been taken from Great Britain, and has now penetrated to countries like Egypt and Persia.

In framing or criticising the constitution of a representative body we encounter practical questions of considerable interest. We have to determine, first, who ought to elect, whether a property qualification should be required, whether owners of property should have more than one vote, whether manhood suffrage, household suffrage, or a more limited franchise will give the best results, and whether women ought to be allowed to vote (see WOMEN'S RIGHTS). We have then to consider how the electors are to be grouped.

The Representation of the People Act (1918) in Great Britain, for example, apportioned approximately 70,000 electors for one M.P., and gave the franchise to some 20 millions (including over 8

million women) out of a population of 42½ millions. It laid down three qualifications—residence, business, and university; men were to be over twenty-one years of age and women over thirty (see PARLIAMENT, *Electors*). Votes may be so distributed, however, that a majority of members is returned by a minority of electors, especially in those elections when there are three or more candidates for one seat. Thomas Hare (1806-91) was the author of a scheme of proportional representation, in which the whole country is treated as one constituency, each elector has one vote, and any candidate obtaining the necessary quota of votes is elected, while provision is made for transferring votes from a candidate who obtains more than the quota by enabling an elector to vote for several names in the order of his preference. Since the example set by Denmark in 1855, Sweden, Finland, Belgium, Australia, South Africa, and other countries have adopted various systems of proportional representation, of which there are altogether about 300. The votes allowed, less in number than the candidates, are non-transferable in Japan. In France and Austria a second ballot is taken between the principal candidates in triangular contests. 'Cumulative' voting enables the elector to give all his votes (as many as there are seats to be filled) to one candidate if he will. Proportional representation is used for Irish Senate and municipal and Scottish Education Authority elections, and, as regards the British parliament, only for the university constituencies.

Passing from election law, we have to consider what are the duties of elected representatives, and what should be their relation to their constituents. Should they be paid? Should they have a long term of office, that they may learn their business, or a short term, that they may never forget their dependence on the electors? Are they delegates, bound to act on the instructions of those who appoint them, or is it their duty to act on their own judgment, and to do what is best for the general welfare? The accepted theory in England is that a member is not a delegate; his constituents have no power to withdraw his mandate, and the member is bound to act on his own judgment. But the highly organised parties of modern times leave very little freedom to the individual representative: he can only secure election by pledging himself to vote for his party on certain issues.

For the Referendum, see INITIATIVE, &c., SWITZERLAND, and, for the representative system of the United States, CONGRESS, PRESIDENT, UNITED STATES. See DEMOCRACY and the articles on the various countries, under heading *Constitution*; also Mill, *Representative Government* (1861); T. Hare, *Election of Parliamentary Representatives* (1859); Lord Avebury, *Representation* (1883); Bryce, *American Commonwealth* (1888) and *Modern Democracies* (1921); de la Chapelle, *Reforme électorale* (1898); books on proportional representation by Commons (1907), J. H. Humphreys (1911), and publications of the P. R. Society; Delbrück, *Regierung und Volkswille* (1914); and Ramsay Muir, *National Self-government* (1918).

Reprieve (Fr. *reprendre*, 'to take back') is the suspension of punishment for a crime, and is used chiefly in connection with capital crimes. The power of suspending all sentences at any time is vested in the crown, or chief-magistrate of a republic, at discretion; and in Britain is exercised through the Home Secretary (see SECRETARY OF STATE, PARDON). There are also several grounds on which the judge or a court reprieves a sentence. Where the judge is not satisfied with the verdict, or is doubtful of the validity of the indictment, he reprieves the sentence in order to give time for some application to the crown. When the prisoner is a pregnant woman, and pleads that fact, it is proper to put off the execution of the

sentence until after her delivery. When a woman pleads her pregnancy as a reason for relieve the traditional practice in England is to empanel a jury of matrons, and, if they bring in a verdict of 'quick with child,' execution is stayed. Another cause of relieve is the insanity of the prisoner, for, if before execution it appear the prisoner is insane, whether the insanity supervened after the crime or not, the judge ought to relieve him. A relieve is usually followed by remission or commutation of the punishment to which the prisoner has been sentenced.

Reprisal is the retaking, from an enemy, of goods which he has seized, or the capture from him of other goods, as an equivalent for the damage he has wrought. Letters of Reprisal are the same as Letters of Marque (q.v.).

Reprobation. See PREDESTINATION.

Reproduction is the general term for the whole sequence of processes by which new individuals arise. From a parent organism, or more usually from two parents, offspring take origin, often at successive reproductive periods, which implies multiplication; these offspring give rise in due time to others, and this implies a sequence of generations. It is not possible to separate reproduction from growth, at the limit of which it usually occurs; or from the activation of the reproductive organs at maturity, in which, in vertebrates, hormones are often concerned; or from the division of labour implied in there being two sexes, egg-producing or female individuals and sperm-producing or male individuals; or from the ways in which the sperm-cell is brought into contact and union with the egg-cell—a process in which the insemination, the pollination and the like, must be distinguished from the microscopic union called fertilisation, to which Weismann applied the useful term *Amphimixis*. But the process of reproduction has also to take account of development; and, it may be also, of the antenatal relation between parent and offspring. Yet again, it has to do with the liberation or separation of the offspring from the parent. Nor can the study of reproduction be separated off from heredity, the relation of organic continuity between successive generations, which secures the begetting of like by like, and yet allows of the emergence of those novelties or variations which form much at least of the raw material of further evolution.

Modes of Reproduction.—In one-celled organisms, whether Protophytes or Protozoa, the unit divides into two or more parts (by fission, budding, and spore-formation) and each of these parts grows into the likeness of the whole. But even at this low level of unicellular life it often happens that two individuals combine to form one (total conjugation), which may then proceed to divide into many. Or specialised reproductive units (gametes), the result of division and sometimes dimorphic, may unite in pairs to form a zygote, which either grows into the original form or proceeds to divide into many individuals. Very suggestive is the partial conjugation of such ciliated Infusorians as the Slipper Animalcule (*Paramecium*), where there is an exchange of nuclear elements and then a separation of the conjugants. This seems to secure vigour and variability in the stock.

Among many-celled organisms, both plants and animals, there is a frequent occurrence of asexual reproduction, in which a considerable part of the parent is separated off to start a new individual. Thus the freshwater *Hydra* gives off buds; a sea-anemone may split longitudinally into two; a ribbon worm or Nemertean may break into pieces; two or three starfishes can actually multiply by separating off their arms; a liverwort may give off

multicellular gemmæ, and a tiger-lily may liberate bulbils. In short, there is great variety of asexual multiplication, and it often leads to the formation of colonies, as in Zoophytes and corals, Bryozoa and Compound Tunicates.

But the big fact is that all the many-celled animals and the great majority of many-celled plants show sexual reproduction, though in certain types the asexual mode may also occur in the same organism. Thus, while the main mode of multiplication in the freshwater *Hydra* is the liberation of asexually-produced buds, there is also sexual reproduction by eggs and sperms. This phrase, sexual reproduction, covers several distinct facts: (a) the formation and segregation of special reproductive cells; (b) the production of two different kinds of special reproductive cells, which are usually inter-dependent; and (c) the production of these (the spermatozoa and the ova) by different (male and female) organs or individuals. (a) In plants like ferns and mosses, one phase in the life-history is the formation of spores. These are special reproductive cells which develop without fertilisation; and in the life-history of the liver-fluke we find not only an adult reproduction by means of egg-cells and sperm-cells, but a larval multiplication by means of spore cells, which can hardly be called ova. See GENERATIONS (ALTERNATION OF). (b) In some animals, such as certain Rotifers (q.v.), the males are not known; and in some other types they are absent for long periods (as in summer green-flies), or unnecessary even when they are present. In other words, parthenogenesis often occurs; and it must be ranked as one of the modes of sexual reproduction. For although there is no fertilisation, there is multiplication by means of egg-cells. (c) Many common animals, such as snails, earthworms, and leeches, are hermaphrodite: that is to say, each organism is both an egg-producer and a sperm-producer, often, it must be noted, at different times (dichogamy). In the cases mentioned there is cross-fertilisation in spite of the hermaphroditism; in a few other cases, such as the liver-fluke and some tapeworms, there is self-fertilisation or autogamy.

Advantages of Sexual Reproduction.—To account for the occurrence of sexual reproduction in almost all organisms with bodies, even when asexual reproduction is also retained, there must be advantages in the sexual method. (1) There is an advantage in the fact that a larger number of offspring can be started at once by the sexual method, and there may also be less of a drain on the resources of the body. That sexual reproduction is often fatal, as in butterflies, is hardly an objection to the general proposition that sexual multiplication, if it is practicable, is less expensive physiologically. Here it may be noticed that it would make for clearness if the term multiplication were used as often as possible for modes of increasing individuals, so that the term reproduction might be kept more or less distinct for modes of sexual union and the like. (2) Although asexual multiplication occurs in some complicated animals, such as Tunicates, it is attended with obvious difficulties in types of high differentiation and integration. Thus it does not occur in arthropods or molluscs, or in any vertebrates above the level of Tunicates. (3) In the third place, the outstanding fact implied in having specialised reproductive units is that they have not shared in the building up of the 'body,' and that they have retained an organisation continuous in quality with the original germ-cell from which the parent arose. They are thus not very liable to be tainted by the mishaps so frequently befalling the 'body' which bears them. A separated off fraction or bud, of sea-anemone or hydra, must start with all the disabilities that the parent

body may have acquired—an obviously undesirable handicap. (4) In the life-history of the germ-cells, and in the mingling of sperm-cell and egg-cell in fertilisation, there is abundant opportunity for new permutations and combinations of hereditary qualities—for variations in short. This is perhaps the crowning advantage of sexual reproduction, that it favours the emergence of the new. In any case we have stated some of the reasons which account for the superseding of asexual by sexual reproduction.

Growth and Reproduction.—Growth involves a multiplication of the complex molecules that constitute the living matter; and in many-celled organisms it also implies the continual multiplication of cells. What in one-celled organisms would be a process of multiplication or reproduction, is in many-celled organisms a mode of growth. Thus, for organisms that multiply asexually, it is plain that reproduction is discontinuous growth; and one of the reasons why it must occur is discoverable in cases where a 'limit of growth' is reached—that is to say, a definite size which is physiologically the optimum for the organism concerned. Beyond this 'limit of growth' there is a setting-in of instability, and this is the prelude to reproduction. The detailed physiology is quite uncertain; but the fact is clear that reproduction tends to occur at the limit of growth, either for the organism as a whole, or for certain parts. In numerous cases, however, the limit of growth is evaded, as in many fishes, reptiles, animal colonies, and plants; and this makes the analysis of reproduction more difficult. In the more highly differentiated organisms, moreover, the periodic occurrence of reproduction cannot be interpreted as the direct result of an instability consequent on reaching a limit of growth, for the regulation of the balance of the body has become very subtle, involving, for instance, a periodic activation of hormone-producing tissue in the reproductive organs or gonads.

The importance of the relation between reproduction and the limit of growth may be illustrated in reference to the cell or any compact one-celled organism. When a growing cell (or unicellular organism) of regular shape, spherical let us say, increases its volume several times, its surface does not increase at the same rate. In fact the volume increases as the cube of the radius, and the surface only as the square. This disproportion is very important, for it is by the surface that the living matter of the cell is fed, aerated, and purified, in short, kept alive. If the cell goes on growing beyond the 'limit of growth,' the profitable size at which the surface balances the requirements of the volume of living matter, instability will set in; and the regulated way of dealing with this is for the cell to divide into two, for this readjusts the ratio of volume and surface. In other words, as Herbert Spencer and Rudolf Leuckart pointed out long ago, the reproduction of the cell occurs at the limit of growth. No doubt other factors have to be considered besides the ratio of surface and volume; thus there is the ratio between the kernel of the cell and the general cell-substance—the ratio of nucleoplasm to cytoplasm; no doubt there is as yet very little understanding of the precise nature of the 'cytolytic,' 'auto-toxic,' 'enzymatic' instability that directly induces the cell-division; no doubt there is difficulty in passing from the consequence of the limit of growth in a single cell to the reaching of the limit of growth in a large animal; but it seems justifiable to say that a consideration of the limit of growth in cells and cell-aggregates throws some light on the physiological necessity for reproduction.

Nutrition and Reproduction.—Another general

idea to be kept in mind is the antithesis between nutrition and reproduction. In conditions of abundant food the common hydra produces many adherent buds, literal reproductions of itself. A bud, while still attached to the parent, may bear buds of its own. Eventually, a check to nutrition occurs; conditions set in which are not favourable to continued assimilation; the buds separate off, and this may be followed by a phase of sexual reproduction.

Similarly a planarian worm in good nutritive conditions may form asexually a chain of four daughter-worms; a check to nutrition may occur; links separate, and sexual reproduction may set in. There are many illustrations of this organic seesaw between nutrition and reproduction. Fruit-trees are root-pruned, because the check to nutrition favours the reproductive activity which we know as flowering and fruiting. But if foliage and vegetative activity is desired, the flower-buds are nipped off. Similarly it is well known that castrated domesticated animals tend to put on flesh and fat. Nutrition and reproduction are antithetic. It is not accidental that the flower oftenest occurs at the end of the vegetative axis, where food-supplies are at a minimum; but this consideration is in itself too simple, for account must be taken of the occurrence of what are called metabolic gradients.

In a simple planarian worm the everyday chemical routine or metabolism is most intense at the anterior end of the body, and gradually wanes to a point distant from the head by about three-quarters of the total length. There the regulative influence exerted by the head is at a minimum, and it is at that point that preparation begins to be made for asexual reproduction and for the development of a second head, namely the head of the posterior part when that is liberated as a separate worm. Behind the minimum line the metabolic gradient rises again, but soon falls again towards the tail. There can be no doubt that the physiology of reproduction must take account of areas where the regulative control of other parts wanes away, and where cells tend to mummy and assert their own individuality.

So, to return to the growing axis of the plant, the growing point is the region with the highest rate of metabolism, and there is a gradual decrease down the stem—a metabolic gradient. Within a variable distance from the growing point a controlling sway is exerted over the incipient buds; they cannot develop until the tip of the stem has grown to some distance away from them. If the growing point is covered with a small cap of plaster of Paris, it loses its physiological dominance, and the buds which were inhibited will begin to develop. If the plaster-cap be removed, the development of the buds will stop and the young shoots will die. But if the lateral shoots developing from the buds had been able to outstrip the apex of the stem before the cap was removed, then the inhibiting power of their growing points will predominate over that of the apical shoot, which will therefore die. Here, then, is another set of considerations to be kept in mind in trying to understand reproduction; but this line of inquiry is still very young.

Adaptations in Reproduction.—In typical vertebrate animals and in many others a rhythm has been established in the body such that reproductive activity sets in at a time of year favourable to the starting of a new generation or a new family. This is, of course, a very complex adjustment, for, while it is of great importance that the young should be born at a favourable time of year, this may be secured not by altering the pairing-time, but by altering the period of antenatal life. Simi-

larly, among seed-plants there may be a long or a short interval between the time of pollination and the time of seed-scattering. And just as an insect may have a long larval life—in the ground or in the water—so a seed may remain for a long time a seed before it becomes a seedling. The life-histories that are most readily interpreted are those of annual animals and annual plants in countries with well defined seasons, for summer is then the time of pairing and pollinating, autumn the time of early development and separation from the moribund parent, winter the time of lying latent and well-protected, whether as seed or cocoon, and spring the time of resumed development and youth. But the variations on this theme are often puzzling. There are many of the rodents that have three or four litters in the year, but this is very different from the state of affairs in not a few insects where there are several generations in a summer. There are slowly-developing types, like elephants and 'century plants,' that are not mature till many years have passed; there are some midges and worms, and two or three amphibians that are reproductive in larval life (paedogenesis). Another set of contrasts is disclosed when we compare: (a) egg-laying animals whose eggs are fertilised outside the body, as in salmon, to take one example out of a million; (b) egg-laying animals whose eggs are fertilised at the moment of liberation, as in frogs; (c) egg-laying animals whose eggs are fertilised inside the body, as in hens; (d) animals whose eggs hatch just as they are being laid (ovo-viviparous), as in the case of some lizards and snakes; and (e) animals in which the young are hatched out within the mother, as in the primitive Peripatus (q.v.), or in the common brown lizard (viviparous). Taking mammals alone: (a) the Monotremes are actually oviparous; (b) the Marsupials are prematurely-bearing, with no true placenta except in Perameles, with no more than a provisional yolk-sac placenta in all the others; (c) the Placentals, including all the other mammals, have a more or less prolonged ante-natal partnership (or symbiosis it might be called) between the mother and the unborn young. This is anticipated in oviducal ante-natal connections in two dog-fishes and in a few other cases. Where a true amniotic and allantoic placenta is developed, as in all mammals above Marsupials, the term eu-placental might be used, and for other symbiotic connections we suggest the terms—pre-placental for cases like Peripatus, para-placental for cases like the two dog-fishes referred to, and vitello-placental for all the Marsupials except Perameles.

Reproduction and Hormones. In a higher animal the reproductive maturity is marked by a multiplication and ripening of the cells in the gonads, which often increase in size at the breeding period and bring about some degree of tumescence. Especially in the male there is a restless urge to secure the relief that the liberation of the reproductive elements brings. But not less important is the activation of glandular endocrinal tissue associated with the reproductive organs, and the result is the production of sex-hormones or gonadal hormones, which are distributed through the body by the blood. These hormones serve to stimulate the development of hitherto latent sex characters, some of which are ancillary to reproduction. Thus the swelling up of the first fingers in male frogs is of service in the sexual amplexus, and the activation of the mammary glands in the female mammal prepares for the future suckling of the young. The hormones prepare various tissues of the female for the reception and fixing of the egg-cell, for the establishment of the placenta, and for similar functions. There is also in both sexes a marked effect on the nervous system, and

this may serve as the liberating stimulus for psychical predispositions which have been previously more or less latent. In highly evolved organisms like birds it is impossible to ignore the psychological aspect of reproduction.

Reproduction and Death.—While reproduction is concerned with the beginning of new lives, it not infrequently involves the ending of the life of the parent. In many cases reproduction is the beginning of death. In some simple animals, such as certain Annelid worms, the parent, especially the mother, may rupture and die in liberating the reproductive elements. The case of the Palolo-worms (e.g. *Eunice viridis*) is of special interest, since the great part of the body, laden with eggs and sperms, is set adrift and breaks up, while the head-end remains in the crevice of the coral-reef and re-grows the body which has been lost. In this case the nemesis of death is evaded, and it is one of the trends of evolution to lessen the physiological expensiveness of reproduction. Some insects, such as mayflies and many butterflies, die in a few hours after reproduction; and the same is true of such strong animals as lamprays and eels. The exhaustion is fatal, and the males are sometimes victims as well as their mates. But among higher animals there is a strong tendency to reduce the sacrifice, not to speak of the fatality, of reproduction. The familiar tragedy of the human mother's death in child-birth must be regarded as altogether exceptional and unnatural.

The Rate of Reproduction and Increase.—The rate of reproduction depends upon the constitution of the individual organism and on its immediate environment and nutrition. The rate of increase, which is much more difficult to estimate, depends upon the wide and complex conditions of life which are often included in the phrase 'the struggle for existence.' While it is true that organisms sometimes exhibit an extraordinary increase in numbers in favourable areas and seasons, and while we know of many forms and even of whole races which have dwindled away and become extinct, the fluctuations in the numbers of plants and animals seem for the most part to be imperceptibly gradual. Their rate of reproduction is adjusted to the conditions of their life; the rise or fall of the population is seldom emphatic. The essay of Malthus (1798), in which he showed that the increase of human population tended to outrun the means of subsistence, but was met by various checks, afforded suggestions to Darwin and Wallace, who extended the induction of Malthus to plants and animals, recognising in their increase the fundamental condition of the struggle for existence, and analysing the checks as various forms of natural selection. But Herbert Spencer's analysis of the laws of multiplication was even more penetrating. Including under the term individuation all those race-preservative processes by which individual life is completed and maintained, and under the term genesis all those processes aiding the formation and perfecting of new individuals, he showed that in evolution there is an inverse ratio between individuation and genesis. Progressive evolution in the direction of individuation is associated with a diminishing rate of reproduction. But this does not imply that personal individuation directly checks personal reproductivity.

The Importance of Reproduction in Evolution.—As almost every individual life begins in the intimate union of two living units—the sperm-cell and the egg-cell—there is in the nature of the organisms' beginning an evident possibility of variation. The two cells, and more especially the nuclei of the two cells, are intermingled; and in the vital combination which results new characteristics may be evolved, old features may be strength-

ened, peculiarities may be averaged off. On fertilisation as a source of variation, emphasis has been laid by Treviranus, Galton, Brooks, and others, while Hatchesek regards the intermingling as an important counteractive of disadvantageous individual peculiarities, and Weismann finds in it the chief source of transmissible variations in many-celled animals.

In considering the evolution of animals great importance is always—and rightly—attached to the self-preserving struggles and endeavours which secure the satisfaction of nutritive needs; but the species-maintaining activities of reproduction have been not less important. Thus, Darwin insisted on the importance of sexual selection as a factor in evolution, and there can be no doubt that courtship has aided in the evolution of the psychical life of animals. Romanes, too, in his insistence on the importance of isolation, recognised 'the reproductive factor in evolution.' For by variations in the reproductive system a species may be divided into mutually sterile sets, which, prevented from intercrossing by this physiological barrier, are free to evolve along divergent paths. In a very different connection, Robert Chambers emphasised the importance of 'prolonged gestation.' Fiske directed attention to prolonged infancy as a factor in evolutionary progress, and Miss Buckley long ago pointed to the open secret that an increase of parental care and sacrifice as seen in birds and mammals has been a factor in, as well as a result of, the general ascent.

The elaboration of ante-natal symbiosis which we observe in the evolution of mammals; the growth of parental care, and the frequent subordination of self-preserving to species-maintaining ends; and finally, the rise of sociality from foundations based in organic kinship, are well-known facts of animal life which suggest the importance of the reproductive factor in evolution.

Reptile-Fund was abolished by Caprivi in 1890. See HANOVER.

Reptiles, a very large class of Vertebrate animals, including Tortoises and Turtles, Lizards of many kinds, the divergent New Zealand 'lizard' *Sphenodon*, Snakes, and Crocodilians—five distinct orders with living representatives, but including also at least as many orders of wholly extinct types, such as Ichthyosaurs, Plesiosaurs, and Dinosaurs.

Reptiles occupy a central position in the Vertebrate series: beneath them are Amphibians and Fishes, above them are Birds and Mammals. They begin the series of 'higher Vertebrates,' which at no period of life breathe by gills, which in embryonic life are provided with two birth-robos or fetal membranes—a protective amnion and a respiratory allantois. Their relationships seem to be threefold, with the Amphibians, with Birds, and with Mammals. But there is no doubt that they are most closely linked to Birds—a fact first clearly

Mammalia on the one hand and Ichthyopsida (Amphibians and Fishes) on the other.

Referring to the article BIRDS for a contrast between Mammals, Birds, and Reptiles, we shall simply notice that Reptiles are cold-blooded, the temperature of the body not greatly exceeding that of the surrounding medium; that the heart is three-chambered, except in Crocodilians, where four chambers first occur; that mostly venous blood goes from the heart to the anterior viscera, and mixed blood to the posterior region, only the head and anterior regions receiving purely arterial blood; that the body is covered with scales, with which subjacent bony plates or scutes are sometimes associated; that the skull articulates by a single condyle with the backbone, and the lower jaw works against the quadrate bone; that the great majority are oviparous, while in some the eggs are hatched within the mother. The earliest remains of Reptiles are found in Permian strata, and the golden age of Reptiles was in Mesozoic, especially in Jurassic and Cretaceous, times.

Classification of Living Reptiles.—As the orders of Reptiles with living representatives are separately discussed, it will be enough here to give a general classification. Order 1, Chelonina: Tortoises and Turtles. 2, Rhynchocephalia: one form—the New Zealand lizard *Sphenodon* (q.v.), whose extinct ancestors date from the Permian. 3, Lacertilia: Lizards (q.v.). 4, Ophidia: Snakes (q.v.). 5, Crocodilia: Crocodiles (q.v.), Alligators (q.v.).

EXTINCT REPTILES.—The classification of the extinct Reptilian types is still very uncertain; but many authorities agree in recognising the following orders:

Anomodontia.—Reptiles with lizard-like body, limbs adapted for walking, biconcave vertebrae, and teeth fixed in sockets. The order is restricted to the Permian and Trias, and exhibits affinities with the Labyrinthodont Amphibians and with Mammals. Among the representative genera are *Pariasaurus*, *Galesaurus*, *Deuterosaurus*, *Dicynodon*, and *Placodus*.

Sauropterygia.—Reptiles without exoskeleton, with long neck and short tail, limbs adapted for walking or for swimming, biconcave vertebrae, teeth fixed in sockets. All of them seem to have been carnivorous. The order is represented from the Trias to the Upper Chalk, and exhibits affinities with Amphibians. Among the representative genera are *Plesiosaurs*, *Mesosaurus*, and *Nothosaurus*.

Ichthyopterygia.—Marine Reptiles, with whale-like body, without exoskeleton, with limbs modified as paddles, with biconcave vertebrae, with teeth implanted in a continuous groove. Many were carnivorous and fed on fishes. Seeley has shown that some were viviparous, the fossilised young being found in the fossilised mothers. The order is represented from the Upper Trias to the Upper Chalk, and exhibits affinities with Labyrinthodont Amphibians and with the New Zealand 'lizard' *Sphenodon*. Among the genera are *Ichthyosaurus* and *Ophialosaurus*. Some attained a length of 30 to 40 feet.

Rhynchocephalia.—As *Sphenodon* is the only surviving representative of the Rhynchocephalia, the order may be almost regarded as extinct. It is represented by Palaeohatteria from the Permian, besides *Champsosaurus*, *Hyperodapeton*, *Rhynchosaurus* from later strata. Within or near this order may also be included a remarkable form *Proterosaurus* from the Permian, a type for which Seeley established a distinct order, *Proterosauria*. The special interest of these forms is, according to

Baur, that they 'are certainly the most generalised group of all reptiles, and come nearest, in many respects, to that order of reptiles from which all others took their origin.'

Dinosauria.—The largest land Reptiles of crocodilian or more bird-like form, represented from the Trias to the Upper Chalk, exhibiting affinities with crocodiles and with birds. Representative genera are *Iguanodon* (sometimes measuring about 30 feet), *Camptosaurus*, *Scelidosaurus*, *Stegosaurus*, *Ceratops* (with long horns on the skull), *Megalosaurus*, *Ceratosaurs* (also horned), *Brontosaurus* (upwards of 50 feet in length), *Atlantosaurus* (with a femur 6 feet long).

Ornithosauria.—Flying reptiles, often called Pterodactyles, with a fold of skin extended on the greatly elongated outermost finger. The order is represented from the Lias to the Upper Chalk by such genera as *Pteranodon*, *Pterodactylus*, *Dimorphodon*, and *Rhamphorhynchus*. Some had an expanse of wing of about 25 feet, but many were small. Their affinities are uncertain.

See Huxley, *Anatomy of Vertebrate Animals* (1879); Nicholson and Lydekker, *Manual of Palaeontology*, vol. II, by Lydekker (Edin. 1890); Hoffmann in *Brown's Klassen und Ordnungen des Thierreichs* (Leip., in progress); Duméril and Bibron, *Épéologie Générale* (9 vols. Paris, 1834-51); British Museum Catalogues by Boulenger &c.; Holbrook, *North American Herpetology* (Phila. 5 vols. 1836-42); Schreiber, *Herpetologia Europæa* (new ed. 1912); Dittmars, *Reptiles of the World* (N.Y. 1922).

Repton, a village of Derbyshire, 7½ miles SSW. of Derby and 4½ NE. of Burton upon Trent. Here was founded the first Christian church in Mercia, of which Repton for a while was the royal and episcopal capital. It was the seat from before 660 till its destruction by the Danes in 874 of a celebrated monastery, as afterwards of an Austin priory from 1172 till the Dissolution. Remains of this priory are incorporated in the buildings of the free grammar-school, which, founded in 1556 by Sir John Porte, has risen to be one of the great English public schools. The parish church has a graceful spire and a very interesting Saxon crypt, 17 feet square.

Republic (*Lat. res publica*, 'the public good'), a political community in which the sovereign power is lodged, not in a hereditary chief, but either in certain privileged members of the community or in the whole community. According to the constitution of the governing body, a republic may therefore vary from the most exclusive oligarchy to a pure democracy. The several republics of Greece and that of Rome were, at the outset at least, aristocratic communities. The mediæval republics of Venice, Genoa, and the other Italian towns were also more or less aristocratic. The sovereign power was held to be vested in the franchised citizens, and every function—legislative, executive, or judicial—not exercised directly by that body could only be exercised by parties deriving their authority from it. But the extent of the franchise, and the mode of exercising it, varied much in these civic communities; and the most prosperous and long-lived was Venice, which was also the most aristocratic of them all. In the 16th century the Seven Provinces of the Netherlands, on their revolt from Spain, adopted a republican form of government, as did Switzerland on becoming independent of the German empire. Great Britain was nominally a republic for eleven years (from 1649 to 1660). France was a republic from 1793 to 1805, and from 1848 to 1853; and the republic was again proclaimed 4th September 1870. Such government as Spain had between February 1873 and 31st December 1874 was of a republican form. France, Switzerland,

Andorra, San Marino, and the free towns within the German empire were the only European republics till Portugal was added in 1910. As a result of the Great War the empires of Germany, Austria, and Russia, with diminished areas, became republics. Hungary remained a kingdom, governed by a regent. Czechoslovakia and Poland are new creations. The Baltic is fringed with new republican states—Lithuania, Latvia, Estonia, and Finland. In 1922 the republics in Russia formed a confederation with the title of Union of Soviet Socialist Republics; and more or less autonomy has since been granted to various areas within the union, some of which bear the name of republic. Republican governments were established in Turkey (with capital at Angora) in 1923, in Greece in 1924, in Albania in 1925. As an experiment in democracy, the most important long-established modern republic is the United States of America. Except during the short-lived empire of 1863-67, Mexico has been a republic since 1824. Since the revolution in Brazil in 1890 all the South American states (omitting the three Guiana dependencies) have been republics, most of them established in the second decade of the 19th century (see SPAIN, *History*). China became a republic in 1912. Persia in 1926 hesitated and drew back. In the republics of the ancient world the franchised classes exercised their power directly without any system of delegation or representation. The same was at first the case in the Swiss cantons, where, however, representative government has been gradually but generally introduced. Modern republics have been founded on the representative, not the direct, system, which can hardly exist except in a community that is very small and concentrated as to space. Germany, Switzerland, the United States of America, and others are *federal* republics, consisting of a number of separate states bound together by a treaty, so as to present to the external world the appearance of one state with a central government, which has the power of enacting laws and issuing orders that are directly binding on the individual citizens. The constitutions of the various republican countries are discussed under then several heads: see especially ATHENS, ROME, VENICE, SWITZERLAND, FRANCE, and UNITED STATES; also FEDERATIONS AND UNIONS, REPRESENTATION, DEMOCRACY.

Republican, a party name in American politics, which has had at different times different significations. In the first years of the Republic it was the alternative title of the Anti-federalists, who advocated the sovereignty of the states and the rights of the people, and finally secured those amendments and additions to the Constitution which were intended to guarantee state rights, and which declared that all powers not expressly granted to congress by the Constitution are retained by the states or the people. Before the war of 1812, however, the term Democrats (q.v.) had been substituted as the title of the party; and the name of Republicans went out of use until 1856, when it was taken up by the new party which was organised to oppose the Democrats, its original holders. This party was formed to combat the extension of slavery; it appealed to all who were opposed to the repeal of the Missouri Compromise (see MISSOURI) and the efforts to make Kansas a slave state (see KANSAS). It grew out of the Free-soil party (see FREE-SOILERS), and at once took the place, as opponents of the Democrats, that the Whig party, which had died of over compromise, had for some time feebly held. In 1856 it nominated Fremont for the presidency, and made a good fight. The decision in the Dred Scott Case (q.v.) and the progress of events in Kansas greatly strengthened the party, and after the divisions

among the Democrats over the same question in 1860 the success of the Republicans was assured. Electing Lincoln in that year, they held office continuously from 1861 to 1885, the Republican presidents being Lincoln, Johnson, Grant (twice), Hayes, Garfield, and Arthur. Since then the administration has been in Republican hands, 1889-93, 1897-1913, and from 1921, the presidents being Harrison, McKinley, Roosevelt, Taft, Harding, and Coolidge. The conduct of the civil war was in the hands of the Republican party, although, of course, northern Democrats formed a large proportion of the Union armies. For its history, see UNITED STATES; and see also SLAVERY. The strength of the party is in the north and west. Republicans claim great credit for their management of the finances of the nation, which brought about the resumption of specie payment. The slavery question has passed into history, and, although the actual enfranchisement of the southern negroes may demand the attention of the party, the principal opposition between Republicans and Democrats now is on the question of tariff, the former being strong protectionists. The Republican party has declared that the Covenant of the League of Nations contains stipulations 'not only intolerable to an independent people, but certain to produce the injustice, hostility, and controversy among nations which it proposed to prevent.'

Republican Bird. See WEAVER BIRD.

Requena, a town of Spain, 37 miles W. of Valencia, cultivates silkworms, saffron, and fruits: pop. 20,000.

Requests, COURT OF, an ancient court of equity in England, inferior to the Court of Chancery, and abolished 1641. Also, a local tribunal (known like wise by the name of Court of Conscience) instituted in London by Henry VIII. for the recovery of small debts. Similar local tribunals elsewhere have all been superseded by the county courts.

Requiem (Lat. *requies*, 'rest') or *Missa pro defunctis*, a special mass of the Roman Catholic Church, sung in commemoration of the Faithful Departed on All Souls' Day (2d Nov.), but also at funeral services and anniversaries of the deaths of individuals. It takes its name from the first words of the Introit, *Requiem æternam*, and differs from the ordinary mass in omitting the *Gloria* and *Credo*, and in inserting the *Dies Iræ*. The most celebrated musical settings of the Requiem Mass are those of Palestrina, Vittoria, Mozart, Cherubini, Berlioz, and Verdi. Brahms's *German Requiem*, a Protestant work, does not fit this definition.

Reredos (Fr.), the wall or screen at the back of an altar. It is usually in the form of a screen detached from the east wall, and is adorned with niches, statues, &c., or with paintings or tapestry. In some cases it is attached to the east wall and is of great size, covering the whole of the wall, as at All Souls College, Oxford. That splendid 15th-century reredos had been plastered over at the Reformation, but was discovered and restored in 1872-76. In Durham Cathedral is a very fine example of a reredos in the form of a detached screen; it was brought by sea to Newcastle from London by Lord Neville in 1380, being perhaps of French workmanship, and was restored in 1846. The lofty reredos (c. 1480) at St Albans, dividing the presbytery from the retro-choir, is of the same type and age as that at Winchester. A good example of the many reredoses erected in newer times is that of Salisbury, designed by Sir G. G. Scott, and erected in 1875 at the cost of Earl Beauchamp to take the place of one demolished about 1790 by Wyatt. Owing to the imagery they contain, they have been the subject of controversy in the

Church of England—e.g. in the case of the Exeter reredos (1873-75), and of that of St Paul's (1889-91),

Reredos, Salisbury Cathedral

both of which were allowed, after frequent appeal, to remain.

Rescripts (Lat. *rescripta*), answers of the popes and emperors to questions in jurisprudence officially propounded to them. *Rescripta principis* were one of the authoritative sources of the civil law, and consisted of the answers of the emperor to those who consulted him, either as public functionaries or as individuals, on questions of law. They were often applied for by private persons, more especially women and soldiers, to solve their doubts or grant them privileges. The rescripts directed to corporate and municipal bodies were known as *Pragmatica sanctiones*, a name which has found its way into the public law of Europe (see PRAGMATIC SANCTION). Rescripts might gradually come to have the force of law, in so far as their determinations in particular cases were of general application.

Rescue, in English law, is the illegal delivery and discharge of a prisoner or of goods out of the custody of the law. If, for example, a tenant whose goods are distrained for rent take them by force from the bailiff, the distrainer has a right of action against the person who rescues the goods. A person who rescues a prisoner accused or convicted of treason, felony, or misdemeanour is himself deemed to be guilty of treason, felony, &c.; the punishment varies with the gravity of the charge. A person who rescues or attempts to rescue a murderer going to execution is liable to penal servitude for life.

Resedaceæ, a family of dicotyledons, mostly herbaceous, having alternate leaves and terminal spikes of hermaphrodite irregular flowers. Chiefly natives of Europe, the Mediterranean region, and the west of Asia, they are mostly mere weeds. Weld (q.v.) and Mignonette (q.v.) are the species most worthy of notice.

Reservation, MENTAL (Lat. *reservatio* or *re-strictio mentalis*), the act of reserving or holding back some word or clause which is necessary to convey fully the meaning really intended by the speaker. It differs from equivocation (Lat. *equivocatio* or *ambiguitas*) in this, that in the latter the words employed, although doubtful, and perhaps not fitted naturally to convey the real meaning of the speaker, are yet, absolutely speaking, and without the addition of any further word or clause, susceptible of that meaning. Few questions in casuistry have excited more controversy, or have been the subject of fiercer recrimination, than that of the lawfulness of equivocation and mental reservation. In the celebrated *Letters of Pascal* (q.v.) against the Jesuits it was one of the most prominent and, used as he employed it, the most effective topics; and Pascal's charges against the Jesuit casuistry of that day have been repeated in almost every popular controversy on the subject which has since arisen. There are several varieties of mental reservation, differing from each other, and all differing from equivocation. But as regards the morality of the subject all the forms of language calculated to deceive may be classed together. Mental reservation is of two kinds, *purely mental* and *not purely mental*. By the former designation is meant a mental reservation which cannot be detected, whether in the words themselves, or in the circumstances in which they are spoken. Of this kind would be the mental reservation implied if a person, on being asked if he had seen A. B. (whom he really had just seen *walking* by), were to reply: 'I have not seen him,' meaning '*riding on horseback*.' A 'not purely mental' reservation is that which, although not naturally implied or contained in the words, may nevertheless be inferred or suspected, either from them or the circumstances in which they are used. Of this kind would be the mental reservation of a servant, in giving the ordinary answer to a visitor's inquiry for his master: 'Not at home,' although his master were really in the house; or that of a confessor, who, in a country where the privileges of the secret of the confessional are known and admitted, on being asked whether a certain person had committed a crime, which the confessor knew from his confession that he had committed, should answer: 'I do not know,' meaning 'outside of the confessional.' And, in general, all such doubtful forms, whether of mental reservation or of equivocation, may be divided into *discoverable* and *undiscoverable*. Much of the odium which has been excited against the casuists for their teaching on this head has arisen from the confusion of their views as to these two classes of mental reservation.

According to the most approved Catholic authorities, 'purely mental' reservations and 'absolutely undiscoverable' equivocations are held to be in all cases unlawful, such forms of speech being in truth lies, inasmuch as they have but one real sense, which is not the sense intended by the person who uses them, and hence can only serve to deceive. This doctrine is held by all sound Catholic casuists, and the contradictory doctrine is expressly condemned by Pope Innocent XI. (Propp. 26, 27). On the contrary, mental reservations 'not purely mental' and 'discoverable' equivocations are held to be not inconsistent with truth, and in certain circumstances, when there is necessity or weighty reason for resorting to them, allowable. An historical example of such equivocation or reservation is in the well-known answer of St Athanasius to the question of the party who were in pursuit of him, and who, overtaking him, but not knowing his person, asked what way Athanasius had gone. '*He is not far off*,' replied Athanasius, and the party passed on in pursuit. And an ordinary

example of discoverable mental reservation is that of a person who, on being asked by one to whom he could not with safety give a refusal, whether he has any money, should reply: 'No,' meaning, 'none to lend to you.' In order, however, to justify the use of these devices of speech, casuists require that there shall be some grave and urgent reason on the speaker's part; as, for example, the necessity of keeping a state secret, or a secret of the confessional, or of a professional character, or even the confidence entrusted by a friend, or the ordinary and fitting privacy which is required for the comfort and security of domestic life and of the peaceful intercourse of society; and that the concealed sense of the form of speech employed, although it may be *actually undiscovered*, and even unlikely to be discovered, may yet be, in all the circumstances, *really discoverable*. Some Protestant moralists admit that in some cases even equivocation is permissible. See the articles CASUISTRY; LIGUORI; and Cardinal Newman's *Apologia*.

Reservation of the Sacrament. See LORD'S SUPPER.

Reserves. In the organisation of the military resources of most European countries the *reserve forces* are, first, those soldiers who, having served some time in the regular army, are still liable to be called upon to rejoin it when raised from a peace to a war establishment on mobilisation; and secondly, those who are liable to be called upon to follow in second and third lines if the occasion requires.

In Great Britain the Army Reserve is an important element in the army organisation, and the Territorial and Reserve Forces Act of 1907 made considerable changes. The Army Reserve consists of men who, having enlisted for 12 years, have served from 3 to 9 years (commonly 7) in the regular ranks. For the 'Special Reserve' see MILITIA. See also ARMY.

A reserve on the battlefield is a body of troops held back by the commanding officer so as to be ready to meet a counter attack, to support a success, or cover a retirement. The *Naval Reserve* is dealt with in the article NAVY.

Resetting, or RECEIVING. See THEFT.

Reshd, a town of Persia, capital of the province of Ghilan, stands near the south-west shore of the Caspian Sea, 150 miles NW. of Teheran. Silk is grown and manufactured, and rice and tobacco are cultivated. Pop. 35,000.

Reshid-ed-Din, Persian historian. See PERSIA (*Literature*).

Residuary Legatee. See LEGACY.

Re'sina, a town of Italy, on the site of ancient Herentanum, 4 miles SE. of Naples, at the foot of Vesuvius and facing the sea. Pop. 24,000.

Resin Cerate. See BASILICON.

Resins, a class of natural vegetable products composed of carbon, hydrogen, and oxygen. They are closely allied to the essential oils, all of which, when exposed to the air, absorb oxygen, and finally become converted into substances having the characters of resin; and in most cases they are obtained from the plants which yield them mixed with and dissolved in a corresponding essential oil. Like the natural oils, the natural resins are usually mixtures of two or more distinct resins, which admit of separation by their unequal solubility in different fluids.

The following are the general characters of this class of compounds. At ordinary temperatures they are solid, translucent, and for the most part coloured, although some are colourless and transparent. Some are devoid of odour, while others

give off an aromatic fragrance from the admixture of an essential oil. In their crude state they never crystallise, but are amorphous and brittle, breaking with a conchoidal fracture; when pure several of them may, however, be obtained in the crystalline form. They are readily melted by the action of heat, and are inflammable, burning with a white smoky flame. They are usually described as non-volatile, but it has been shown that common resin may be distilled in a current of superheated steam. They are insoluble in water, but dissolve in alcohol, ether, and the essential and fixed oils. They are insulators or non-conductors of electricity, and become negatively electric by friction. Many of them possess acid properties, in which case their alcoholic solutions redden litmus. These resins combine with the alkalis, and form frothy soap-like solutions in alkaline lyes. The resinous soaps thus formed differ from ordinary soap in not being precipitated by chloride of sodium.

The resins are divisible into the *hard resins*, the *soft resins*, and the *gum-resins*. The hard resins are at ordinary temperatures solid and brittle; they are easily pulverised, and contain little or no essential oil. Under this head are included copal, the varieties of lac, mastic, and sandarach, and the resins of benzoin (commonly called gum-benzoin), jalap, guaiacum, &c. The soft resins admit of being moulded by the hand, and some of them are viscous and semi-fluid, in which case they are termed *balsams*. They consist essentially of solutions of hard resins in essential oils, or admixtures of the two. They become oxidised and hardened by exposure to the air into the first class of resins. Under this head are placed turpentine, storax, balsam of copaiba, and the balsams of Canada, Peru, and Tolu. The gum-resins are the milky juices of certain plants solidified by exposure to air. For these, see GUM.

The resins are very widely diffused throughout the vegetable kingdom. They are generally obtained by making incisions into the wood of the trees which produce them; sometimes, however, they exude spontaneously, and in other cases they require to be extracted from the wood by boiling alcohol. The crude resins are separated from the essential oils with which they are usually mixed by distillation with water, the resin remaining while the oil and water pass off; and from the gummy and mucilaginous matters by alcohol, which dissolves out the pure resins, which can be precipitated from their alcoholic solution by the addition of water. The resins are extensively employed in medicine and the arts.

Various fossil resins are known, of which the most important is Amber (q.v.). Some chemists place bitumen and asphalt amongst this class; and amongst the fossil resins described by mineralogists may be mentioned Fichtelite, Hartite, Idrialite, Ozokerite, Scheererite, Xyloretin, &c.

The common resin, or rosin, of commerce exudes in a semi-fluid state from several species of pine, especially *Pinus Teda*, *P. mitis*, *P. palustris*, and *P. rigida* of North America, *P. Pinaster*, *P. Pinca*, and *P. Laricio* of southern Europe, and *P. sylvestris* of northern Europe. The crude article, consisting of turpentine and resin proper, is subjected to distillation, when the resin alone remains behind. The resin thus procured is used very extensively in the manufacture of common yellow soap, also for sizing paper and various other purposes, including the preparation of ointments and plasters in pharmacy.

The other resins most generally known and used in Europe, and here all treated in separate articles, are Anime, Copal, Danmar, Mastic, Sandarach, Frankincense, Lac, and Kauri Gum. A number of resinous substances are now made synthetically.

Res Judicata, in Law, means that the subject-matter of an action has been already decided by a court of competent jurisdiction. A matter so decided cannot again be made a ground of action, as between the same parties.

Resolution, in Music, the relieving of a discord by a following concord; see HARMONY. For the Resolution of Forces, see COMPOSITION.

Respiration, or BREATHING, is a part of the life of all organisms. It consists of a series of changes, the first of which is the entrance of oxygen into the body, and the last the excretion of certain waste materials, the chief of them being carbonic acid. For the general relation of respiration to the other bodily functions see PHYSIOLOGY. The corresponding gaseous exchange in plants is dealt with in the article on PHYSIOLOGY (VEGETABLE). Here we shall describe the process as it occurs in man and other mammalia, leaving a sketch of the methods adopted in other types of animals (comparative respiration) for effecting the same purpose to a later paragraph.

The respiratory apparatus consists in mammals of the lungs and of the air-passages which lead to them. In aquatic animals the gills fulfil the same functions as the lungs of air breathing animals. The muscles which move the chest and the nerves which supply them must also be included under the general heading Respiratory System, and using this expression in the widest sense, it includes all the tissues of the body, since they are all concerned in the using up of the oxygen and the production of waste materials such as carbonic acid.

Essentially a lung or gill is constructed of a thin membrane, one surface of which is exposed to the air or water, as the case may be, while on the other is a network of blood-vessels—the only separation between the blood and aerating medium being the thin wall of the blood-vessels and the fine membrane on one side of which vessels are distributed. The difference between the simplest and the most complicated respiratory membrane is one of degree only.

The lungs or the gills are only the medium for the exchange, on the part of the blood, of carbonic acid for oxygen. They are not the seat, in any special manner, of those combustion-processes of which the production of carbonic acid is the final result. These processes occur in all parts of the body in the substance of the tissues.

It is therefore usual to divide the respiratory process into *external* and *internal* respiration. External respiration is the gaseous exchange in the lung or gill, oxygen passing there to the blood from the aerating medium, and the carbonic acid in the opposite direction. Internal respiration is the reverse exchange which occurs in the tissues, and is associated with the life of the cells; here the oxygen in the blood is utilised by the cells, and replaced by the carbonic acid which they form as a result of their activity (oxidation). Of the two, internal respiration is the more important, but we shall not be able to study this until we have considered the relationship of the oxidation process to nutrition. External respiration is merely the beginning (the entry of oxygen) and the final phase (the exit of carbonic acid). In man and related animals it is the blood which carries the gases named from lungs to tissues, on the one hand, and from tissues back to the lungs on the other (see CIRCULATION). In the blood the gases are not merely in solution, but are in loose or easily dissociable combinations with certain substances, as we shall see later. One of these substances, called *hemoglobin*, is specially concerned with the carriage of oxygen, and merits a few preliminary

words. Hæmoglobin is the name of the red pigment of the blood, and its temporary union with oxygen is called oxyhæmoglobin; this is formed in the lungs, then carried by the arterial blood to the tissues, where it is dissociated or reduced (i.e. deprived of its respiratory oxygen), and returns in the venous blood to the lungs for a fresh supply of oxygen. The venous blood contains also the waste-product carbonic acid which is discharged from the body in the lungs. The pigment is contained not in the fluid part of the blood (blood-plasma) but in the red or coloured corpuscles which float in it, and forms their main constituent. Chemically it is a conjugated protein—that is, protein or albuminous material (globin) united to an iron-containing substance known as hæmatin ($C_{54}H_{33}O_{50}ON_4Fe$). In round figures hæmoglobin contains 0.4 per cent. of iron.

In many simple animals which have no circulatory or respiratory systems, and possess no blood, the gaseous exchange occurs at the whole surface of their bodies, and higher in the scale there is also a certain amount of cutaneous respiration. Thus, animals such as the frog, which have thin skins, can breathe with—i.e. the gases can diffuse through—the whole surface of their bodies if the under skin is well supplied with blood-vessels. A frog for this reason can live for days without its lungs, but if its skin is rendered impervious to gases will die very quickly, even with the lungs intact. But, as all the mammalia have thick skins, this method of breathing must be reduced to a minimum.

Structure of the External Respiratory Apparatus in Mammals.—This mechanism consists of the lungs, a series of minute air-chambers with a network of capillaries in the walls, the air-passages from the air-chambers of the lungs to the outer air, and the chest-walls with their muscles, which act like bellows and change the air in the lungs. The essentials of structure that a lung must possess have already been alluded to. The simplest lung that we can imagine would be an elastic membranous bag, well supplied with blood-vessels, and with a pipe connecting it with the air; the most complicated that exist are essentially of that construction, the complications that occur having for their object merely the enlarging of the surface exposed to the air. Let us begin with the air-passages. There are first the nose and mouth; these join the upper part of the gullet, known as the pharynx (see DIGESTION). From the pharynx arises the windpipe (trachea); this passes through the voice-box (larynx) into the chest-cavity; there it divides into two passages (the bronchi), one for each lung; the bronchi go on dividing again and again; the ultimate divisions (the bronchioles) open into clusters of air-chambers or alveoli. The air-chambers are about $\frac{1}{16}$ th inch in diameter. It has been estimated that there are some 725 millions of them, and that their total surface is about 2000 square feet. The walls of the air-chambers are formed of a thin membrane in which the blood and lymph capillaries ramify. The membranous walls are partly formed of elastic tissue. It is this that gives to the lungs their elasticity. The larger air-passages (trachea and bronchi) are kept open by horseshoe-shaped rings of cartilage; muscles stretch between the poles of the horseshoe, complete the ring, and permit the size of the passages to vary, at the same time resisting over-distension when the internal pressure rises. These larger air-passages are lined by a mucous membrane, containing mucous glands; the innermost layer is a ciliated epithelium; the cilia lash upwards, and thus keep the passages free from mucus and remove foreign particles. As the passages become smaller they lose their cartilages, and the muscles form a continuous circular layer. The lungs are invested by

a membrane (the visceral pleura). At the root of the lungs this membrane is continuous with a membrane which lines the chest-cavity (the parietal pleura). The potential space between the two is the pleural cavity; it is in reality a lymph space, and communicates with the lymphatics of the pleura. Owing to the air-pressure within the lungs the two pleurae are closely pressed together, the lungs entirely filling the chest-cavity. If the chest-wall is punctured the lungs partially collapse owing to their elasticity, and the respiratory movements are unable to move the air in the lungs.

The chest is an air-tight chamber enclosing the lungs and the heart.

The walls of the chest are formed of bones (the ribs, sternum, and backbone) and muscles; the bones and muscles are so arranged that the size of the chest-cavity can be altered. In this way the chest acts as a bellows and moves air in and out of the lungs. The ribs are sloped slightly downwards, especially after an expiration; when an inspiration is taken certain muscles fix the upper ribs, and those muscles connecting the ribs to each other contract and the ribs are raised, and thus the size of the chest-cavity is increased. At the same time a flattish muscle called the Diaphragm (q.v.), which separates the chest cavity from the rest of the body-cavity, and which after an expiration is arched upwards (by the pressure of the abdominal viscera upon it), forcibly contracts, becomes flatter, and therefore enlarges the size of the chest-cavity, forcing the abdominal viscera downwards and causing the abdomen to protrude. (The relation of the lungs to the other main organs will be seen in the illustration at ABDOMEN; see also that at DIAPHRAGM.) In these two ways, then, the size of the chest-cavity may be increased. The result of this enlargement is that the pressure of the air within the cavities of the lungs is lowered; air therefore flows without rushes through the nostrils (mouth-breathing warms the incoming air insufficiently) down the windpipe into the lungs, and thus a fresh supply of oxygen is introduced. The movements which produce this result are known as the inspiratory movements. In making an expiration the reverse effects are produced; the chest-cavity becomes smaller, the pressure of the air in the lungs increases, and some rushes out through the nostrils into the air until the pressures inside and outside are equalised. An ordinary expiration is effected by the elasticity of the lungs, by the passive fall of the ribs, and by the elasticity of the chest and abdominal walls. An ordinary inspiration is therefore the result of active muscular contraction, while an ordinary expiration is the result of mere passive elasticity of the parts concerned. There are certain other respiratory movements to be considered. During inspiration and expiration the glottis (the open-

The Trachea (windpipe), Bronchi, and one of the Lungs in section.

ing between the vocal cords of the larynx; see LARYNX) undergoes a rhythmical widening and narrowing; this movement is greater in forced than in quiet breathing. During inspiration also the nostrils dilate; in most cases perhaps the inspiration has to be rather a forced one before they do so. Forced respiration occurs when the supply of oxygen is insufficient, or when carbonic acid accumulates in the blood. Any muscle that can aid in enlarging and decreasing the size of the chest-cavity is called into play. The average amount of air, in the case of an individual 5 feet 8 inches in height, that goes in and out of the lungs at each inspiration and expiration is about 30 cubic inches; this is called the tidal air. By means of forced inspiratory movements the ingoing tide may be increased by 100 cubic inches; by means of a forced expiration the outgoing tidal air may be increased by 100 cubic inches. After the most forced expiration possible, although an extra 100 cubic inches can be expired, there always remain within the lungs about 1000 cubic inches of air. So that if we take as deep a breath as possible, and then make as forced an expiration as we can, we shall drive out $100 + 30 + 100 = 230$ cubic inches of air. This is termed the respiratory capacity. Since the tidal air is only 30 cubic inches, and 200 cubic inches remain in the chest after an ordinary expiration, it follows the air directly changed during respiration is not in the main that really within the air sacs or alveoli of the lungs themselves, but is that within the nose, windpipe, and larger bronchi, the pipes that result from the branching of the windpipe. Therefore the changes of the air within the essential parts of the lungs are largely the result of diffusion between it and the purer air of the bronchi, aided by the rush with which the tidal air flows in. Taking the tidal air as 30 cubic inches (500 c.c. expanded at body temperature to 600 c.c.), Haldane gives the capacity of the upper air-passages as 200 c.c.; therefore about a third of the tidal air is required to fill this *dead-space*, but adequate ventilation is secured by alternate inspirations and expirations. The quantity of air which passes in and out per minute is termed total ventilation; normally it is 5 to 10 litres per minute in the adult; after walking up a hill it rises to 30, and maximal readings up to 100 after heavy exercise have been recorded. *Alveolar ventilation* is the portion of this total which reaches the air-sacs; it may be approximately measured by subtracting the volume of the dead-space multiplied by the number of respirations per minute from the total ventilation.

The Spirometer.—The methods adopted for obtaining such data are numerous. The first observer of note was Dr John Hutchinson in the early years of the 19th century. He invented the *spirometer*, a modified gasometer into which an experimenter breathes. This instrument has been considerably improved of late years, especially by Krogh. Its usefulness for determining the volume of the tidal air, the respiratory capacity (sometimes called vital capacity), &c., in testing the efficiency of asthma, has been abundantly demonstrated. The mercurial manometer has also played a part in evaluating aviators' efficiency. The subject blows into one end as hard as he can in order to raise the mercury as high as possible, or having raised it, say, to 40 mm., sees how long he can keep it at that height. The force with which the respiratory muscles are capable of acting is greatest in the vital capacity of the height of from five feet seven inches to five feet eight inches, and will elevate a column of nearly three inches (about 70 mm.) of mercury. Above this height the force decreases as the stature increases; so that the average of men of six feet can elevate only about two and a half inches of mercury. The force manifested in the strongest expiratory acts is, on the average, one-third greater than that exercised in inspiration. But this difference is in great measure due to the power exerted by the elastic reaction of the walls of the chest; and it is also much influenced by the disproportionate strength which the expiratory muscles attain, from their being called into use for other purposes than that of simple expiration. In ordinary quiet breathing there is a negative pressure of only 1 mm. during inspiration, and a positive pressure of from 2 to 3 mm. during expiration. The greater part of the force exerted in deep inspiration is employed in overcoming the resistance offered by the elasticity of the lungs.

In man the pressure exerted by the elasticity of the lungs alone is about 6 mm. of mercury. This is estimated by tying a manometer into the trachea of a dead subject, and observing the rise of mercury that occurs on puncture of the chest-wall. If the chest is distended beforehand so as to imitate a forcible inspiration, a much larger rise (80 mm.) of the mercury is obtained. During life this elastic force is assisted by the contraction of the plain muscular fibres of the alveoli and bronchial tubes, the pressure of which probably does not exceed 1 or 2 mm. Haldane has calculated that the total force of contraction by the muscles in the act of inspiring 200 cubic inches of air is more than 450 lb.

The Collection of Alveolar Air.—Haldane and Priestley introduced a simple method of collecting alveolar air which has the advantage of being applicable to man. A piece of rubber tubing was taken about 1 inch in diameter and about 4 feet long. A mouthpiece is fitted into one end. About 2 inches from the mouthpiece a small hole is made into which is inserted the tube of a gas-receiver. The gas-receiver is fitted at the upper end with a three-way tap, and the lower end is also closed by a tap. Before it is used, the gas-receiver is filled with mercury. The subject of the experiment breathes normally through the tube for a time, and then, at the end of a normal inspiration, he expires quickly and very deeply through the mouthpiece and instantly closes it with his tongue. The lower tap of the receiver is then turned, and as the mercury runs out a sample of the air takes its place and fills the receiver; this sample is then analysed. A second experiment is then done, in which the subject expires deeply at the end of a normal inspiration, and another sample obtained. The mean result of the two analyses gives the composition of alveolar air, mixed with any of the air of the 'dead-space'. The analyses show that the normal oxygen pressure in it is 13 per cent. of an atmosphere approximately equal to 100 mm. of mercury.

The Douglas Bag.—In the collection of data no piece of apparatus of recent years has given such valuable results as this one. The volume of air breathed is measured by observing that of the expired air. This is not quite the same thing as the volume of inspired air, because the carbonic acid added to it is

the explanation of this see later under *Respiratory quotient*. The subject breathes through a tube provided with suitable valves. By attaching a tube to the expiratory valve the expired air can be collected in a bag devised by Dr C. G. Douglas of Oxford, made of canvas impregnated with rubber, impervious to gas, flexible, and not too heavy. It is fitted with a tap which can be quickly turned so that the duration of an experiment can be limited exactly. The sample collected is kept for subsequent measurement and analysis. The tubing used for connecting the face-mask to the bag must have a very wide bore; even a small constriction adds greatly to the labour of respiration. We all know by experience that a trifling spasm of, or small accumulation of phlegm in, the natural air passages increases the discomfort of breathing.

The volume of the sample is obtained by squeezing the contents of the bag through a gas meter, and a side tube allows of the collection of a small sample for analysis. In this way (1) the total ventilation, (2) the oxygen in the expired air, and incidentally the oxygen absorbed by the subject, (3) the CO_2 in the expired air, as its output per minute, and (4) the respiratory quotient (the proportion of CO_2 given out to oxygen taken in) are obtained. These data are also needed in reference to work on nutrition, and are especially necessary in determining what is called '*basal metabolism*', i.e. the amount of oxygen used or carbonic acid produced during complete physiological rest, and this is employed as the standard of comparison with what occurs in the greatly increased figures in conditions of muscular work.

The usefulness of the apparatus may further be illustrated by the record of an actual experiment (rather an extreme case), which shows the efficiency of the deep over the shallow type of breathing. It was performed upon two people in each of whom the alveolar O_2 was 10 per cent. The respiration rate was the same (200 c.c.), but in one the respiration rate was 10 and in the other 30 per minute.

	Case 1	Case 2
a. Respiration rate	10	30
b. Dead-space	200 c.c.	200 c.c.
c. Alveolar respiration per breath	8000 c.c.	2400 c.c.
d. Total ventilation per breath (b × c)	800 c.c.	400 c.c.
e. per minute (a × d)	8000 c.c.	12,000 c.c.
f. Product of a and c (alveolar respiration per minute)	6000 c.c.	6000 c.c.

To achieve the same result in alveolar respiration the shallow breather breathes three times as often and passes more total air (12,000 c.c.) into his respiratory system than the deep breather (8000 c.c.). The shallow breather, moreover, retains half of each breath in the dead-space, instead of a quarter, and the air here is ineffectual so far as gaseous exchange is concerned.

Rate of Respiration.—The ordinary respiratory movements differ in the two sexes and at different periods of life. In young children the chest is altered in size chiefly by the movements of the diaphragm, and the protrusion of the abdominal wall during inspiration is therefore very marked. In men also it is the diaphragm which is chiefly operative, but the ribs are also moved. In women

it is the movement of the ribs, especially the upper ones, which is the most extensive. The respiratory rhythm is the time relation of the acts of inspiration and expiration. It is usually expressed as follows: In. = 3, Ex. = 4, pause = 3. The number of respirations in a healthy adult person usually ranges from 14 to 18 per minute. It is greater in infancy and childhood. It varies also much according to different circumstances, such as exercise or rest, health or disease, &c. Variations in the number of respirations correspond ordinarily with similar variations in the pulsations of the heart. In health the proportion is about 1 to 4, or 1 to 5, and when the rapidity of the heart's action is increased, that of the chest movement is commonly increased also; but not in every case in equal proportion. It happens occasionally in disease, especially of the lungs or air-passages, that the number of respiratory acts increases in quicker proportion than the beats of the pulse; and, in other affections, much more commonly, that the number of the pulse-beats is greater in proportion than that of the respirations.

The Breath Sounds.—If the ear is placed in contact with the wall of the chest, or is separated from it only by a good conductor of sound or stethoscope, a faint respiratory or vesicular murmur is heard during inspiration. This sound varies somewhat in different parts—being loudest or coarsest in the neighbourhood of the trachea and large bronchi (tracheal and bronchial breathing), and fading off into a faint sighing as the ear is placed at a distance from these (vesicular breathing). It is best heard in children, and in them a faint murmur is heard in expiration also. The cause of the vesicular murmur has received various explanations. Some think that the sound is actually produced in the alveoli, but most observers hold that the sound is produced by the air passing through the glottis and larger tubes, and that this sound is modified in its conduction through the substance of the lung. The alterations in the normal breath-sounds, and the various additions to them that occur in different diseased conditions, can only be properly studied at the bedside.

In fact, the whole subject bristles with medical questions, and further information of that side of the subject will be found in text-books on medicine. The organs of external respiration are the seats of the commonest diseases to which mankind is heir, from the common cold upwards. See, however, the articles BRONCHITIS, PLEURISY, PNEUMONIA, TUBERCLE, TUBERCULOSIS, &c.

Before we can pass on to the subject of nutrition and the part played by the tissues in internal respiration, it will be first convenient to study the blood, which is the medium by which the organs of external respiration (lungs, &c.) are brought into communication with the tissues; in connection with the blood it will be necessary to consider the questions of the blood-gases and the way in which the exchange of these between the blood and the air in the lung-alveoli is brought about, the reaction of the blood, and incidentally the part played by the nervous system in the regulation of breathing.

THE GASES OF THE BLOOD.—Before one can study the chemistry of respiration or its regulation, which is in part a chemical process, it is necessary to have a conception of the laws which govern the retention of oxygen and carbonic acid in the blood; but as the blood presents so many complications, we will at the outset consider the solution of gases in such a simple medium as water.

If water is shaken up with oxygen or other gas a definite amount of the gas will dissolve in the water, and under the same conditions the same quantity of gas will dissolve. The conditions that affect that amount are (1) *temperature*, which is important, but to simplify matters we will suppose the temperature remains constant, and so we will neglect that factor

for the present; (2) the *pressure of the gas* to which the water is exposed; and (3) the *solubility of the gas* in water. This is a property of the gas itself; some gases (for instance, oxygen) are but slightly soluble in water, while others, such as carbonic acid, are very soluble. The volume of gas which 1 c.c. of the liquid dissolves is called its *coefficient of solubility*. The effect of the second factor named, the pressure, is quite simple, namely, there is direct proportionality between the amount dissolved and the pressure. Double the pressure, and you double the amount of gas entering into solution; halve it, and you halve the amount, and so on. The results obtained might be plotted out on squared paper, giving quantities on the ordinate, and pressures on the abscissa; the 'curve' so obtained would naturally turn out to be a straight line. But with oxygen and carbonic acid in blood the curves are not straight lines. Expressed in the shape of a formula for gas and water

$$Q = K \times \frac{P}{P'}$$

where Q is the quantity of gas, K the coefficient of solubility, P the atmosphere pressure (760 mm. of mercury) and P' the pressure of the gas to which the liquid was exposed. The value of K at atmospheric pressure for oxygen is 0.04 c.c., and for carbonic acid 1 c.c. Further, when two or more gases are mixed together, each of them produces the same pressure as if the others were absent, and the total pressure of the mixture is the sum of the partial pressures of the individual gases in the mixture (Dalton-Henry Law).

Further, when the gas is dissolved in the liquid it exerts pressure there also; a familiar illustration of this is seen in an ordinary bottle of soda-water. When the cork is first drawn the imprisoned gas exerts high pressure and causes frothing, until after the bubbling ceases as the pressure falls. The pressure of a gas dissolved in a fluid finally equals that of the same gas in the atmosphere to which it is exposed, and as many molecules of the gas leave the fluid as enter it, and there is equilibrium. The pressure of the gas in the fluid is conventionally termed *tension* (T), so when there is equilibrium and $P' = T$, our formula reads $Q = K \times \frac{P}{T}$, and we must carefully distinguish between

the quantity of gas dissolved in a fluid and its *tension*.

There are numerous instruments (gonimeters) for measuring the tension of gases in fluids; but the best for blood is known as Krogh's bubble tonometer. Briefly, it is a vessel introduced on the course of the circulating blood; into it a small quantity of an (exhale of air) is placed. Exchange of gases takes place between the bubble and the blood, and the former is soon in equilibrium with the latter. When it has done so, the bubble is drawn into a small tube and analysed.

As an example, suppose the bubble on analysis proved to consist of 4 per cent. carbonic acid and 12 per cent. oxygen, together with nitrogen and aqueous vapour. The gas in the instrument was compressed by the pressure of the arterial blood (say 120 mm. of mercury) in addition to the atmospheric pressure of 760 mm. of mercury, and therefore the total pressure was $120 + 760 = 880$ mm. of mercury. Four per cent. of this would have been due to the carbonic acid; 4 per cent. of 880 is 35.2. Twelve per cent. would have been due to the oxygen; 12 per cent. of 880 is 105.6. That is, the carbonic acid and oxygen tensions would have been in round figures 35 and 106 mm. of mercury respectively.

Measurement of the Quantity of the Gases of the Blood. This may be done by means of an air-pump, or by a chemical method.

(1) The extraction of the gases from the blood by means of the mercurial air-pump depends upon the fact that blood gives off all its gases when it is boiled in a vacuum. The total gas obtained is first measured, then the carbon dioxide is removed by caustic potash, and the gas that remains consists of oxygen and nitrogen; the oxygen is then removed by pyrogallic acid, and the residual gas is nitrogen. (2) The chemical method depends on the fact that when a solution of oxyhemoglobin is shaken with potassium ferricyanide it gives off the same amount of oxygen as it would when boiled in a vacuum. The blood is therefore first laked with dilute ammonia, the ferricyanide solution is 'spit into it and the oxygen which comes off is measured in a suitable apparatus. After this, tartaric acid is added to the mixture, this liberates the carbonic acid, which is then measured in the same way.

The chemical method is not quite so accurate as the vacuum pump, but it is much more convenient for the study of many problems, as it requires less blood, and, owing to its simplicity, a great number of observations can be made upon a single animal, or it can be used for the systematic investigation of the blood in man. We can now proceed to an examination of the blood-gases themselves.

Oxygen in Blood.—From every 100 c.c. of arterial blood, about 20 c.c. of oxygen can be removed by the air-pump. Nearly all of this oxygen is chemically combined with hemoglobin: the amount in actual solution in the blood is 0.7 c.c. for every 100 c.c. of blood. The quantity of oxygen which 100 c.c. of blood takes up is called the '*oxygen capacity*,' which should not be confounded with the '*specific oxygen capacity*' defined below. In normal human blood the figure is 18.5 c.c.

Hemoglobin owes its value as a respiratory pigment to three principal facts. (1) It can unite

with a large quantity of oxygen, and therefore blood can carry about thirty times as much oxygen to the tissues as plasma would under the same conditions. (2) The interaction between hemoglobin and oxygen is a reversible one; the two unite in the lungs, where the pressure of oxygen is considerable; but when oxygen is absent or at a low pressure, as in the tissues, the hemoglobin parts with its store of oxygen. (3) The oxygen is readily displaced from the blood-pigment by carbonic acid. At most, 1 gramme of hemoglobin can unite with 1.34 c.c. of oxygen. This figure is not quite constant, probably on account of slightly different forms of globin (the protein constituent of hemoglobin) united with the hamatin (the iron-containing constituent) in different animals. The relation between the respiratory oxygen and the iron of the hemoglobin is, however, quite constant, and is called the 'specific oxygen capacity.' Each gramme of iron in hemoglobin unites with 400 c.c. of oxygen; these figures are in the relation of one atom of iron to two atoms of oxygen. The reversible nature of the reaction may therefore be expressed by the equation which in its simplest form runs $\text{Hb} + \text{O}_2 \rightleftharpoons \text{HbO}_2$. A reversible reaction is one which will go in either direction according to the concentrations of the substances present; thus if the concentration of oxygen in solution is increased, more of the hemoglobin will become oxyhemoglobin; and if it is diminished, oxyhemoglobin will break up into hemoglobin (usually called reduced hemoglobin) and oxygen.

The reader must be clear that when we speak of the concentration of oxygen in solution we mean in physical solution, that is, not united chemically with the hemoglobin. This quantity varies in the direct ratio of the oxygen pressure to which the hemoglobin solution is exposed; therefore the problem before us is to determine the relative quantities of oxy- and reduced hemoglobin when a hemoglobin solution is shaken up with oxygen at different pressures.

Suppose we have six small vessels (Barcroft's saturators) and each contains a few c.c. of a solution of hemoglobin and gases of the following composition:

No. 1.	Nitrogen and no oxygen.					
No. 2.	Nitrogen and enough oxygen to give 5 mm. oxygen pressure.					
No. 3.	"	"	"	10	"	
No. 4.	"	"	"	20	"	
No. 5.	"	"	"	50	"	
No. 6.	"	"	"	100	"	

Each vessel is rotated in a bath at body temperature for about fifteen minutes, i.e. until the oxygen and hemoglobin have interacted; the solution is then withdrawn and examined for the relative quantities of oxy- and reduced hemoglobin. The figures would be:

	No. 1.	No. 2.	No. 3.	No. 4.	No. 5.	No. 6.
Percentage of reduced hemoglobin	100	63	45	28	13	6
Percentage of oxy-hemoglobin		0	37	55	72	87
						94

If the pressures of oxygen are plotted horizontally, and the percentages of oxy- and reduced hemoglobin vertically, a curve is obtained called the *oxygen dissociation curve of hemoglobin*.

In the blood itself, as distinguished from a solution of pure hemoglobin, there are additional conditions that influence such a curve, especially the high temperature of the body, the presence of certain salts, and the presence of acids, especially carbonic acid. These three factors tend to make the oxyhemoglobin molecules break down more rapidly and form more rapidly. From the point of view of the body's needs it is clearly necessary not only that hemoglobin should acquire oxygen at the pressure of that gas in the lungs, and part with it at the diminished oxygen pressure in the tissues, but that the two processes should occur at about the same rate, that is, within one second, which is about the time occupied by any given portion of blood in travelling along the capillaries. It would be futile to have an oxygen carrier in the blood

which took a fraction of a second to acquire its oxygen and a fraction of an hour to release it. Yet a solution of pure hemoglobin is just such a substance, for its power of acquiring oxygen is very great, and its power of releasing it is very small. Happily, however, a hemoglobin solution and blood are two very different things. In the red corpuscles, the hemoglobin is dissolved in a medium containing various salts, of which those of potassium are most prominent; these salts confer on oxyhemoglobin the property of giving up its load of oxygen when exposed to low concentration of oxygen in the capillaries of the tissues, while the reduced hemoglobin acquires oxygen more readily at the higher oxygen pressure such as the blood is exposed to in the capillaries of the lungs. This is assisted by the high body temperature and the presence of carbonic acid. Observations on the rate of oxygenation and reduction at body temperature, in the presence of the salts named, and of carbonic acid at the same tension as that which pervades the body (about 40 mm. of mercury) show that the two processes present an extraordinary degree of symmetry, so wonderfully has nature adapted the conditions of life in order that the needs of the body may be served by a substance hemoglobin, which alone is but ill adapted for oxygen-transport.

A comparison of the curves of dissociation presents to the eye graphically the superiority of hemoglobin as an oxygen carrier when it is present in the actual blood over that which it possesses in a pure solution. In the blood itself one sees that at an oxygen pressure of over 60 mm. of mercury (the pressure in the lung alveoli is about 100) the blood will nearly saturate itself with oxygen, and that at pressures below 50 the blood loses its oxygen rapidly, whilst at 10 mm. pressure it is nearly completely reduced.

Research has also shown that the relation of hemoglobin and salts is more fundamental than a mere question of solution. Hemoglobin may be regarded as a weak acid which unites with any available base, so that the material actually present in the red corpuscles is in part potassium hemoglobinate. Oxyhemoglobin is a stronger acid than reduced hemoglobin, so that when the latter takes up oxygen it adds to its store of potassium. Indeed the more that is discovered about hemoglobin the more complex its reactions become. Professor A. V. Hill considers that all the known facts can only be explained on the assumption that when hemoglobin unites with oxygen it breaks up into globin and some form of hamatin, and that the hamatin unites with the oxygen; this recombines with globin to form oxyhemoglobin, which then unites with an increased quantity of potassium. The bases (K and Na) in the red corpuscles vary in relative amount in different animals. In man it is mostly K, in ruminants Na.

Carbonic Acid in Blood.—The relations of carbonic acid in blood, though similarly complex, illustrate the remarkable chemical adaptation of which the living body is susceptible. Carbonic acid, as already stated, renders oxyhemoglobin less stable, so that it yields up its oxygen more readily. If blood is exposed to oxygen and varying admixtures of CO_2 , its hemoglobin contains less oxygen the more CO_2 is present in the mixture. If carbonic acid tends to displace oxygen, it is also true that oxygen tends to displace carbonic acid. This has been quantitatively studied by exposing the blood to an atmosphere of CO_2 to which varying amounts of oxygen are added; and further, it can be shown that at any particular pressure oxygenated blood contains less CO_2 than reduced blood. When, therefore, the blood passes from an artery to a vein, its loss of oxygen may be attributed to two causes acting jointly: (1) the reduction in partial pressure of the oxygen which withdraws oxygen from the blood, and (2) the increase of partial pressure of CO_2 which expels it. In like manner oxygen enters the blood-corpuscles in the lung because (1) of the increased partial pressure of oxygen in the plasma forces it

in, and (2) because the CO_2 by diffusing away from the hæmoglobin makes it easier for the oxygen to go in. Similar statements apply to the entrance and exit of the flow of CO_2 into and out of the blood; in the lung it is partly withdrawn by diffusion into the alveoli, and partly expelled by the entrance of oxygen. Although by the air-pump 100 volumes of blood yield 50 or more volumes of CO_2 , the whole of the gas is not present in simple solution, but by far the larger amount is present in loose combination either with hæmoglobin or with salts (carbonates or bicarbonates). The chemical processes involved in the action of CO_2 on hæmoglobin are not beyond controversy. Some observers, notably Buckmaster, regard the action as simple and represented by the equation:

CO_2 would thus act like the gases CO and NO , a view which has not yet met with general acceptance, chiefly because all known acids act as CO_2 does, and it is by no means proved that such acids form compounds analogous to HbCO and HbNO . Another view may be adopted provisionally: this is based on the assumption that the sodium or potassium salt of hæmoglobin unites with oxygen more readily than does free acid. We have in the blood three acids, oxyhæmoglobin, reduced hæmoglobin, and carbonic acid, and two bases, sodium and potassium, and among the acids oxyhæmoglobin is a stronger acid than reduced hæmoglobin. The base present is not sufficient to satisfy all three, and will be distributed between them. Suppose in a hypothetical example there are 100 available atoms of base; and of these oxyhæmoglobin takes 30, reduced hæmoglobin 10, and CO_2 takes the remainder 60. Suppose next that all the reduced hæmoglobin is turned into oxyhæmoglobin by the entry of oxygen; this being a stronger acid than reduced hæmoglobin can seize base from the bicarbonate; hence the total hæmoglobin will now obtain not 40 but 60 atoms of the base, and the CO_2 will be left with 40; bicarbonate will thus be broken up and the CO_2 will have no alternative but to be expelled. If now we force back CO_2 into the solution in sufficient quantity to retake the base the reverse change will occur, ending in the withdrawal of Na and K from the oxyhæmoglobin, its consequent change to reduced hæmoglobin and the expulsion of the oxygen.

We may conclude this section of this article by giving a summary, and compare the gaseous content of arterial and venous blood. The average quantities in human blood are:

	For 100 volumes of blood,	
	Arterial.	Venous.
Oxygen....	18.5	12
Carbonic acid.	50	56
Nitrogen.....	2	2

The amount of nitrogen is small, and is simply dissolved in the blood from the air; it has no physiological significance. The important gases are the other two; the numbers given for venous blood are mean figures, and vary not only in different veins, but even in the same vein under varying conditions of tissue activity. We see, however, that on the average every 100 c.c. of blood which pass through the lungs gain 6.5 c.c. of oxygen and lose 6 c.c. of carbonic acid. We will now study the mechanism by which this gaseous interchange is effected.

THE GASEOUS EXCHANGE IN THE LUNG.—The simplest explanation is that the process is one of mechanical diffusion. This view is generally regarded as adequate for normal breathing, and can be maintained if it can be shown that the pressure of oxygen in the alveolar air is as great as or greater than the tension of oxygen in the arterial

blood, and therefore *a fortiori* greater than that in venous blood. The oxygen pressure (100 mm. of mercury) in the alveolar air is less than in the atmosphere (152 mm.), is greater than the oxygen-tension in venous blood (35 mm.), hence oxygen passes from alveolar air to blood-plasma; the hæmoglobin immediately combines with it and thus the plasma is left free to absorb more oxygen, and this goes on until the hæmoglobin is saturated with oxygen. The reverse change occurs in the tissues where the pressure of oxygen is small (varying from 35 mm. to zero) and lower than in the plasma or in the lymph which bathes the tissue elements; the plasma parts with its oxygen to the lymph, the lymph to the tissues, and the oxyhæmoglobin then undergoes dissociation to supply more oxygen to the plasma and lymph, and thus in turn to the tissues once more. This goes on until the oxyhæmoglobin loses on the average about half its store of oxygen: 1 c.c. of arterial blood contains 0.2 c.c. of oxygen; 1 c.c. of venous blood contains 0.1 c.c. of oxygen. The measurements of the oxygen pressure (or CO_2 pressure) in alveolar air (collected by Haldane and Priestley's apparatus), and of the oxygen or CO_2 tension in the blood (by the tonometer) has been carried out largely by Krogh in animals, and it is seen that the oxygen-pressure of the alveolar air is always *higher* than the oxygen-tension of the arterial blood, and the CO_2 pressure of the alveolar air is always *lower* than the CO_2 tension of the arterial blood.

Some authorities doubted the applicability of such results to man and affirm that in cases of definite oxygen-want, such as during violent muscular exercise, or on the tops of high mountains, the lining epithelium of the pulmonary alveoli can, by a process of active secretion, transfer oxygen from the alveolar air to the blood. (That secretion is not impossible is shown by studying the swim-bladder of fishes. It morphologically corresponds to the lung, and the oxygen in it is far in excess of what can be explained by mere diffusion from the sea-water; this storage of oxygen, moreover, ceases when the vagus nerves which supply it are divided.)

To meet this objection an experiment was recently devised and carried out at Cambridge; its idea was to repeat as nearly as possible Krogh's work on a man experiencing oxygen-want. Professor Barcroft, who submitted to the experiment, lived for six days in a respiration chamber in which the oxygen pressure in the inspired air was gradually reduced from 130 mm. Hg on the first day to 84 mm. on the last; 84 mm. Hg corresponds to that experienced at an altitude of about 18,000 feet. At the close of the experiment Barcroft's radial artery was laid bare and a cannula inserted so that his arterial blood could be collected either when he was at rest or performing work; his alveolar air was collected and examined simultaneously. The following results were obtained.

	During Rest	During Work
Pressure of oxygen in alveolar air	68 mm. Hg	57 mm. Hg
Tension of oxygen in arterial blood	60 "	48 "

More recently Krogh's bubble aerometer has been applied to man, the blood being withdrawn from an artery by a hypodermic syringe. By this method comparisons have been made of the oxygen-tension in the arterial blood and alveolar air, both at the sea-level and at Cerro, a mining-town in the Andes (14,200 feet). In both cases equilibrium seems to be attained so closely that the difference between the two is within the region of experimental error:

	Barometric Pressure	O_2 Pressure in Alveolar Air	O_2 Tension in Arterial Blood
Cambridge	761 mm. Hg.	100 mm.	90
Cerro	458 "	58 "	59
Edinburgh	755 "	102 "	101

The following table summarises the main facts in relation to the two gases, and the arrows show the direction in which they pass, which is always from higher to lower pressures:

	Pressure (Tension) of Gases.			
	Lungs	Arterial Blood.	Venous Blood.	Tissues.
Oxygen	100 mm.	Just under 100 mm.	85 mm.	0 to 35 mm.
Carbonic Acid	40 mm.	Just over 40 mm.	48 mm.	over 48 mm.

THE REGULATION OF RESPIRATION.—There are three factors, each of which plays a part in maintaining and regulating the rhythmic movements of respiration. They are the respiratory centre, the vagus nerves, and the chemical condition of the blood.

1. *The Respiratory Centre.*—In the central Nervous System (q.v.) there is a specialised small district called the *respiratory centre*. This gives out impulses which travel down the spinal cord to the centres of the spinal nerves that innervate the muscles of respiration. It also receives various afferent fibres, the most important of which are contained in the trunk of the vagus, a nerve from the same part of the brain which supplies many of our internal organs. The vagus is chiefly an afferent nerve in relation to respiration. It, however, also is in a minor degree efferent, for it supplies the muscular tissue of the lungs and bronchial tubes. The respiratory centre was discovered by Flourens; it is situated in that part of the brain-stalk known as the medulla oblongata (see BRAIN) and coincides in position with the sensory centre of the vagus. The existence of subsidiary respiratory centres in the spinal cord has been mooted, but the balance of experimental evidence is against their existence. Flourens found that when the respiratory centre is destroyed respiration at once ceases, and the animal dies. He therefore called it the 'vital knot' (*nœud vital*). The centre is affected not only by the afferent impulses which reach it by such nerves as the vagus, but also by those from the cerebrum; so that we have a limited amount of voluntary control over the respiratory movements. The respiratory centre is probably twofold, consisting of an inspiratory and an expiratory centre. Of these two the inspiratory centre is so much the more active that its importance is a subject of universal agreement; whereas, the existence of an expiratory centre is doubted by some physiologists, who regard expiration as a mere cessation of the active process of inspiration, and a mechanical falling-back of the tissues into their places.

2. *The Nervous Factor in Respiration.*—During each normal respiration, an impulse passes from the lungs to the respiratory centre by the vagus nerve. This can be detected by observing the sign of nerve-activity—viz. an electrical change (current of action) which always accompanies an impulse. The most sensitive apparatus for this purpose is the string-galvanometer of Einthoven. During normal breathing, then, it appears that the inspiratory centre alone is active, which is then checked by an inhibitory impulse that comes from the lung *via* the vagus nerve. But, even if both vagus nerves are cut through, respiration does not cease; the respiratory centre has therefore an inherent rhythm. In forced respiration the galvanometer shows again that the vagus nerves are active, and a second action-current during the expiratory phase suggests the view that there exists the double centre (inspiratory and expiratory), held by many physiologists—e.g. Dr Head. On dividing the vagus of one side of an animal Head observed (as others before him had also done) respiration became slightly slower and deeper; on dividing the second nerve—i.e. the vagus on the other side of the neck—this effect was more marked, but it is not constant, and when it does occur it is only temporary. On exciting the central, i.e. the upper, end of the divided nerve, inspiratory efforts increased until at last the diaphragm came to a standstill in the inspiratory position. But if a weak stimulus was employed the reverse was the case; the expiratory efforts increased, inspiration becoming weaker and weaker, until at last the diaphragm stopped in the position of expiration.

Head's interpretation of these previously-known facts was, in the light of further experiments now to be described, the following: There are in the vagus two sets of fibres, one of which produces an increased activity of the inspiratory part of the respiratory centre, and the other an increased activity of the expiratory part of that centre. Stimulation of the first stops expiration and produces inspiration; stimulation of the second does the reverse. The question now is, What is it that normally produces this alternate stimulation of the two sets of fibres? If we discover this we shall discover the prime moving cause in the alternation of the inspiratory and expiratory acts. It was sought and found in the alternate distension and contraction of the air-vesicles of the lungs where the vagus terminations are situated.

In one series of experiments *positive ventilation* was performed; that is, air was pumped repeatedly into the lungs, and so increased their normal distension; this was found to decrease the inspiratory contractions of the diaphragm, until at last they ceased altogether, and the diaphragm stood still in the expiratory position.

In a second series of experiments, *negative ventilation* was performed; that is, the air was pumped repeatedly out of the lungs, and a condition of collapse of the air-vesicles produced. This was found to increase the inspiratory contractions of the diaphragm, expiration became less and less, and at last the diaphragm assumed the position of inspiratory standstill.

Head regards ordinary respiration as an alternate positive and negative ventilation, though not so excessive as in the experiments just described. Inspiration is positive ventilation, and so provides the nervous mechanism of respiration with a stimulus that leads to expiration. Expiration is a negative ventilation, and so provides the stimulus that leads to inspiration. We must naturally be on our guard against regarding the forcible inflations and deflations produced by a pump as completely analogous to the changes produced in the lungs by ordinary breathing; nevertheless, the two sets of impulses are undoubtedly called into action if the respiratory processes are sufficiently energetic, and of the two sets of impulses those which are started by the inspiratory movement play a more active part in the regulation of respiration than those started by the expiratory movement, so much so that in unlaboured breathing they alone need be considered.

Physiologists are now occupied with the influence of the sympathetic nerves on respiration, but that subject is at present unripe for definite statements.

If positive and negative ventilation are used together rapidly and alternately at a rate quicker than the respiratory rhythm, both inspiratory and expiratory processes are inhibited, and the respiration ceases for a short time. This follows naturally from the experiments previously described. This can also be done voluntarily by oneself taking a number of deep breaths rapidly. The cessation of breathing, called *apnoea*, is not due, as at one time supposed, to over-oxygenation of the blood, but is, according to Head, produced reflexly; for under normal conditions arterial blood is almost fully oxygenated. Apnoea is observed if inert gases, such as nitrogen or hydrogen, are used instead of air. The pause, however, is then shorter, as the blood becomes venous, and in a short time stimulates the respiratory centre to activity. Under abnormal conditions, namely, after division of the vagi, apnoea obviously cannot be due to such reflex action. Fredericq held that even ordinary apnoea had a chemical rather than a nervous origin. He attributed it, however, not to over-oxygenation, but to a lessening of the carbonic acid in the blood, which is the view now adopted. This brings us to—

3. *The Chemical Factor in Respiration.*—Haldane and Priestley found on examining alveolar air that under constant atmospheric pressure the carbonic acid or carbon dioxide exerts an almost constant

pressure in the alveolar air of the same person. In different individuals this pressure varies somewhat, but averages 40 mm. in men and 37 in women and children. With varying atmospheric pressures they concluded that the percentage varies inversely as the atmospheric pressure, so that the pressure of CO_2 remains nearly constant. This conclusion, which has had to be somewhat modified, was a sufficiently close approximation to the truth to focus attention on the sensitiveness of the respiratory centre to slight changes in the tension of CO_2 in the arterial blood. These observations and the next to be described furnish the chemical key to the cause of the amount of pulmonary ventilation: it plays an important part in conjunction with the respiratory nervous system in the regulation of breathing. For the respiratory centre is not only affected by the impulses reaching it by the vagi and other afferent nerves, but it is also very sensitive to any rise in the tension of carbon dioxide in the blood that supplies it. The changes in the tension of this gas in the arterial blood are normally proportional to the changes in the carbon dioxide pressure in the alveoli, and the changes in the lung alveoli are transmitted to the respiratory centre by the blood. They found that a rise of 0.2 per cent. in the alveolar carbon dioxide pressure is sufficient to double the amount of alveolar ventilation during rest. During sudden muscular work the alveolar carbon dioxide pressure increases slightly, and the pulmonary ventilation is consequently increased.

The limitations in Haldane and Priestley's deductions became apparent when observations were made at different altitudes. At the summit of Monte Rosa (15,000 feet), for example, the carbonic acid pressure in the alveoli drops from 40 to 28 mm. Hg. If Haldane and Priestley were correct, respiration should then stop for want of the necessary stimulus; but respiration does not cease under these conditions; modifications of their view were therefore imperative; these may be considered in the next paragraph.

Many physiologists consider that the action of carbonic acid is not specific, but that other acids act in the same way, and that the real stimulus to the respiratory centre is the total acidity of the blood (hydrogen-ion concentration). A rise in the carbonic acid in the blood will, other things being equal, produce an increase in its hydrogen-ion concentration, and so stimulate the respiratory centre. At high altitudes, however, even though the CO_2 present in the blood falls, the hydrogen-ion concentration is maintained by the simultaneous excretion of alkali by the kidneys. This is called 'decrease of alkali reserve.' During exercise, too, the total ventilation of the lungs may so increase as to sweep a lot of the CO_2 out of the blood; but even then in spite of the fall in CO_2 pressure the hydrogen-ion concentration may rise owing to the presence of lactic acid. A fuller consideration of the meaning of the reaction of the blood is postponed to a further section. Another view has been advanced—viz. that the sensitiveness of the respiratory centre increases with reduction of the oxygen tension in the blood, even if this is slight. So that if a man has a total ventilation of 6 litres per minute at the normal CO_2 alveolar pressure, then if the oxygen tension in his blood is reduced, a smaller alveolar CO_2 pressure may be enough to stimulate the centre and produce a total ventilation, say, of 12 litres per minute. In its extreme form this view leads its upholders to believe that CO_2 is a *specific* stimulus. Haggard and Henderson point out that the stimulating effect produced by oxygen-want appears before any increase of lactic acid can be detected; their opponents might retort that the lactic acid (due to lack of oxygen in the brain)

may be formed in the respiratory centre itself. The reader without bias may be neutral and say that while increase in H-ion concentration (whether resulting from carbonic acid or not) produces its effect on the respiratory centre, CO_2 acts apparently in a specific manner because it diffuses into the cells of the centre more rapidly than any other acid. Excessive oxygen-want, however, causes a feeble type of respiration.

The onset of exercise increases the total ventilation before any chemical changes have time to have occurred; this initial increase is attributed to the influence on the respiratory centre of the higher regions of the brain.

The relative importance of the nervous and chemical factors in normal breathing may be briefly stated as follows: The inspiratory centre makes an effort, the degree of exhalation of the centre, and therefore, the magnitude of the effort, more especially in the matter of depth, is governed by the tension of acid (and especially the carbonic acid) in the blood, but it is cut short by an inhibitory impulse passing up the vagus, only to begin again when the effects of this inhibitory impulse are removed.

During fetal life the need of the embryo for oxygen is small, and is amply met by the transference of oxygen from the maternal blood through the thin walls of the fetal capillaries in the placenta. But when the child is born, this source of oxygen is no longer available, and the increasing vascosity of the blood stimulates the respiratory centre to action, and is the essential cause of the first inspiratory effort. The newborn child makes to obtain the oxygen it requires. It is said that if the placental circulation is stopped while the child is still in *utero*, respiratory efforts are also made. Some regard the action of the air on the body surface as an accessory cause of the first respirations, and it is the practice to increase this in feeble children by stimulating the cutaneous nerves by the application of cold water to the skin. Such treatment always causes deep inspirations, even in the adult. There are other nerves stimulation of which influences the respiratory act; for instance, stimulation of the central end of the glossopharyngeal inhibits the respiratory movements for a short period; this accounts for the very necessary cessation of breathing during swallowing. Stimulation of the central end of the cut superior laryngeal nerve, or of its terminations in the mucous membrane of the larynx, as when a crumb is 'swallowed the wrong way,' produces an increase of expiratory efforts, culminating in coughing. There are many abnormalities of respiration familiar to the doctor in which the nervous mechanism is largely concerned; for instance, this is so for the spasmodic croup of children, for asthma, and for whooping-cough.

Before passing on to the next item on our programme (the acidity of the blood) it will be convenient to interpolate a brief consideration of artificial respiration and of ventilation, using the word in its generally accepted meaning, and not in the more specialised sense in which we have used it hitherto.

Artificial Respiration.—In experiments on animals in which it is necessary to open the chest, life can be maintained by pumping air into the lungs; this is done by means of some form of pump or bellows.

Artificial respiration is sometimes necessary in man to restore normal breathing, as for instance in those who are apparently dead from drowning. In such cases speed in commencing the artificial breathing, and perseverance in continuing the process are essential. Many have been restored to life after the efforts have been continued for an hour or more. It is now recognised that of the numerous methods that introduced in 1901 by Sir E. Sharpey Schafer of Edinburgh is the simplest and most effective. It has superseded the older methods of Marshall Hall and Silvester: the operator kneels by the side of or *athwart* the patient, who is laid on the ground face downwards with a thick folded garment under his chest. He faces the patient's head, and places his hands on each side over the lower ribs, then slowly throws the weight of his body forward, and thus forces air out of the lungs of the subject; he then gradually relaxes the pressure by

bringing his body up again, but without removing his hands. This is repeated regularly at the rate of twelve to fifteen times a minute until the patient breathes, or until all hope of restoration is given up. In no case should the treatment be given up for at least half-an-hour. Bystanders may help the principal operator by applying hot flannels to the body and hands of the patient; but until respiration has been re-established the clothes should not be removed nor any attempt made to give restoratives by the mouth. As the patient lies face downwards there is less risk than in other methods of the tongue falling back into the pharynx, and at the same time water and saliva or mucus can continue to escape by the mouth. In certain cases where there is obstruction in the wind-pipe, surgical interference may be necessary (see TRACHEOTOMY).

Ventilation.—Some observers have stated that certain noxious substances are ordinarily contained in expired air which are much more poisonous than carbonic acid, but careful researches have failed to substantiate this. If precautions be taken by absolute cleanliness to prevent admixture of the air with exhalations from skin, teeth, and clothes, the expired air only contains one noxious substance, and that is carbonic acid. Absolute cleanliness is, however, not the rule; and the air of rooms becomes stuffy when the amount of expired air in them is just as much as to raise the percentage of carbonic acid to 0.1 per cent. An adult gives off about 0.6 cubic feet of carbonic acid per hour, and if he is supplied with 1000 cubic feet of fresh air per hour, he will add 0.6 to the 0.4 cubic feet of carbonic acid it already contains; in other words, the percentage of that gas will be raised to 0.1. An hourly supply of 2000 cubic feet of fresh air will lower the percentage of carbonic acid to 0.07, and of 3000 cubic feet to 0.06, and this is the supply which is usually recommended. In order that the air may be renewed without giving rise to unpleasant draughts, each adult should be allotted sufficient space in a room, at least 1000 cubic feet.

Leonard Hill has pointed out that the effects of bad ventilation are not so much due to changes in the chemical composition of the air, as to the absence of movement in the air; moving air has a stimulating, and still air a depressing effect.

THE REACTION OF THE BLOOD.—Research has given us a method which represents the exact meaning of the words acidity and alkalinity.

When hydrochloric acid is added to water the water becomes acid because the HCl dissociates into its component ions of hydrogen and chlorine. If no complex acids are used, one of the ions is hydrogen, and the degree of acidity depends on the number of hydrogen ions in solution. HCl is a strong acid because the dissociation is nearly complete, and therefore serves as a standard. In the same way the degree of alkalinity depends on the concentration of hydroxyl (OH) ions, but in all solutions the product of the concentrations of H and OH ions is constant. Pure water dissociates to a trifling extent into H and OH ions, and we call water neutral, not because it is neither acid nor alkali, but because it is both in equal degree. In a solution that turns blue litmus red the H ions preponderate, but OH ions are not absent; in a solution which turns red litmus blue, the reverse is the case.

Blood is a fluid which turns red litmus blue, and so is spoken of as alkaline, but it also contains H ions. A constituency which returns a Liberal member to Parliament is labelled a Liberal constituency, but this does not mean it boasts no Conservatives. This analogy may help us to realise what one means in speaking of the acidity of the blood. The unit of acidity is the concentration of H ions in a normal solution of HCl (36.5 grammes to the litre). The H ion concentration of the blood is inconceivably small, being relatively to this unit only 0.000,000,032, or one gramme ion in 32 million litres. Small as this number is variations in it produce profound physiological disturbances; if the

figure in arterial blood rose to 0.000,000,034 breathing would be appreciably affected, and if it rose to 0.000,000,05 the person would be hopelessly out of breath. The chief acid to which this is due is carbonic acid, which in water becomes hydrogen carbonate (H_2CO_3); if carbonic acid gas (CO_2) is passed into water, or a physiological saline solution in increasing amount, the concentration of hydrogen ions increases also. Carbonic acid is continually being thrust into the blood by the tissues, but normally this produces no great preponderance of H ions, and the reaction is but little disturbed; this is because the blood-plasma contains certain substances spoken of as 'buffers' which enter into combination with the CO_2 , and so prevent it raising the acidity of the blood-fluid. The most important of these substances is sodium bicarbonate. The total amount of CO_2 in the blood is just about equal to that which water would absorb when shaken with the pure gas at 760 mm. pressure, but so small a quantity of this in the blood is free that the blood is in equilibrium with a CO_2 pressure of only about 40 mm. Hg (5 per cent. of an atmosphere). The maintenance of the acid-base equilibrium in the blood is most important. The various cells and tissues it nourishes demand a reaction which is next door to neutral, and perhaps there is no other collection of cells which are so sensitive to variations from the normal as those which make up the respiratory centre; the figures already given show how a very slight increase in the hydrogen-ion concentration of the blood stimulates them to excessive action, and produces exaggerated breathing (hyperpnoea). Such a rise in hydrogen-ion concentration is termed *acidemia*.

We have now to consider the way in which the normal acid-base relationship is maintained. Our present views concerning this equilibrium and its regulation teach that of the multitude of substances present in the blood-plasma only two need be taken into account. One of these is CO_2 , which, when it is dissolved in water, is *acid* (H_2CO_3); the other is sodium bicarbonate (NaHCO_3), and this is *alkaline*. The way in which the relative concentrations of these two substances affect the hydrogen-ion concentration of the blood is quite simple, viz. that the hydrogen-ion concentration varies directly with the ratio of the one substance to the other. To shorten the long phrases employed it has been agreed that the words 'concentration of' shall be expressed by square brackets and hydrogen ion by H^+ . Concentration of hydrogen ions thus is abbreviated to $[\text{H}^+]$, and this, as stated above, varies as $\frac{[\text{CO}_2]}{[\text{NaHCO}_3]}$, or what

comes to the same thing, $[\text{H}^+] = \frac{k[\text{CO}_2]}{[\text{NaHCO}_3]}$, k being a constant.

Suppose now a person was to hold his breath, the quantity of CO_2 in solution in his plasma would increase. If he could by an effort of will keep this up until he doubled the quantity of CO_2 in solution, he would also double the $[\text{H}^+]$ in his blood. If he did the opposite experiment, and by forced respirations he reduced the CO_2 in his blood to half, the $[\text{H}^+]$ would also be halved. These results could only be obtained if one assumes that the concentration of NaHCO_3 remains unaltered. But such an assumption is incorrect, for the lung is not the sole regulator of $[\text{H}^+]$. CO_2 , being a gas, is excreted by the lung; but NaHCO_3 , being a solid in solution, leaves the body by the kidney. This introduces us to the second organ which regulates the $[\text{H}^+]$ of the blood. Just as excess of CO_2 stimulates the respiratory mechanism, so excess of NaHCO_3 (or more correctly excess of alkalinity) throws the kidney into activity. Therefore in the experiment

cited above, where the CO_2 is 'washed out' by forcible breathing, the plasma will become more alkaline; the kidney will then begin to excrete NaHCO_3 . In other words, the two important substances we are concerned with both leave the blood, and the proportion between them will not be appreciably altered, that is $[\text{H}^+]$ will remain approximately the same as before. To the question why lung and kidney conspire to maintain in such a perfect way the constancy of the $[\text{H}^+]$ of the blood, no answer is at present possible.

The simplest case of a physiological upset of the acid-base equilibrium is ordinary muscular exercise. Here more CO_2 from the muscles passes into the blood, the respiratory centre responds to the rise of $[\text{H}^+]$, and the increased ventilation of the lungs which follows leads to the removal of the excess of CO_2 . In more violent exercise other acid substances (mainly lactic acid) are produced in addition, and more complicated resonances of the body come into play; in disease also there are other complications, so that a study of the question is now occupying the attention of physicians. Such conditions are found in kidney and heart disease, in diabetes, and in surgical shock, to mention only a few. If the patient recovers, the restoration of the acid-base equilibrium is an important factor in recovery; if the patient remains ill or dies, his resources to this end are not effective. This is obviously not the place to discuss medical details. It will be sufficient to state that abnormal acids may be formed (as in diabetes) or excreted by the kidneys, and that at times other basic substances, of which the most important is ammonia, are thrust into the blood by the tissues.

The methods of estimation of acidity must be left to technical treatises. The only point of importance which we will mention here is the meaning of a conventional sign P_n or pH , which is now in general use. Water, the standard of neutrality, contains 1 gramme of hydrogen ion in 10 million litres. All acid solutions contain more than this amount of H -ion concentration; the OH -ion concentration is disregarded and is always obtainable by calculation, since the product of the two concentrations is a fixed quantity. Instead of saying that water has a hydrogen-ion concentration C_n of 1/10,000,000 grammes, this is shortened to 10⁻⁷ grammes per litre, 10⁻⁷ means 1 divided by 10⁷ or 10,000,000. The 10 and the minus sign are omitted and the figure left is 7; 7 is called the P_n . (To be quite correct, the P_n of neutrality at standard temperature is 7.07. The reader should note that it has a negative sign, so that increase of P_n means decrease of acidity, and vice versa.) Similarly a 1/1000 normal acid has a H -ion concentration of 1/1000 grammes or 10⁻³ grammes per litre. Its P_n is therefore 3; the P_n of blood is very near the neutral point. One sees that the P_n numbers are really logarithmic. The difference in the P_n of pure water (7.07) and of blood (7.6) is a difference in the region of the infinitely little, but as seen in our discussion of respiration these minute differences are of profound physiological importance.

The Effect of Respiration on the Circulation.—It need hardly be mentioned that breathing is so essential that it influences the well-being of the whole body; its relationship to the circulation of the blood is specially close. The main result is a rise of arterial blood-pressure during inspiration, and a fall during expiration. These variations are chiefly the result of the mechanical conditions dependent on the lungs and heart with its large vessels being contained within the air-tight thorax. If the intra-thoracic pressure is measured, it is found that it varies from -5 to -7 mm. of mercury at the end of expiration to -30 at the end of a deep inspiration—that is to say, from 5 to 7 to 30 mm. less than the atmospheric pressure (760 mm. of mercury). The pressure outside the heart and large thoracic vessels is correspondingly diminished during inspiration to the same extent, and produces its main effect (distension) upon the veins because they are never fully distended, and because the pressure within them is low. This results in a proportionately

more rapid flow of blood into the thorax, and therefore into the right side of the heart. Consequently the output from the right side of the heart increases, and thus *via* the pulmonary circuit the inflow into the left side of the heart is increased; in its turn, therefore, the output from the left ventricle rises, and so the aortic pressure is raised. This effect would be counteracted if the aorta and its branches within the thorax were as easily affected by changes of the intra-thoracic pressure as are the thin-walled and easily distensible veins; the thick wall of the aorta and its branches, however, prevents them from undergoing much change of this kind during ordinary breathing. The conditions in the veins are reversed when, with the expiratory act, the thorax returns to its former size; therefore the arterial blood-pressure falls.

To put it in a few words, when the chest cavity is enlarged in inspiration, not only is air sucked into the lungs but more blood is also sucked into the veins and so into the heart. In expiration the reverse occurs.

We thus see that these various conditions produce during inspiration an increased flow of blood into the right heart; this increased supply of blood is then passed *via* the pulmonary circuit to the left heart; this takes a little time; hence it is that the effect of inspiration in raising arterial pressure is not seen at the very commencement of the inspiration. In fact, in some animals which normally breathe very quickly (for instance, the rabbit) inspiration is over and the next expiration has begun before the rise in arterial pressure occurs. In artificial respiration in animals with an open thorax the respiratory undulations on the arterial blood-pressure curve are in the reverse direction. Forcible inflation with air (increased intra-alveolar pressure) produces an increased resistance to the pulmonary circulation, and the rate of flow into the left side consequently falls; the aortic pressure therefore falls, while the pressure in the pulmonary artery rises. Hence the effect of inflations of the lungs at the ordinary respiration rate is to diminish the aortic blood-pressure; this rises again, for the opposite reasons, in the intervals of deflation which correspond to expiration.

The mechanical explanation of the variations in blood-pressure with ordinary respiration takes no account of any nervous co-operation which is held to account partly for the parallelism in respiration and arterial pressure. It is noticed how slowly the heart often beats during the expiratory period; the changing rate of the heart is determined by rhythm in the activity of the vagus centre. When the vagi are cut the inequality in the heart rate disappears, but the respiratory waves in the blood-pressure continue. Whether the cause of the alteration of vagus rhythm is due to a reflex *via* the pulmonary branches of that nerve, or to an 'overflow' from the neighbouring respiratory centre, is a matter of difference of opinion. But after all, the variations in heart rate can only be a minor reason for the parallelism of the two curves. Another factor which some believe to be concerned in the expiratory undulations of arterial pressure is a rhythmical excitation of the vaso-motor centre, occurring coincidentally with the discharges from the respiratory centre. The idea is expressed in the word 'overflow.' Considering how closely the various centres in the medulla oblongata are connected by association fibres, it would not be surprising if the rhythm in one affected its neighbours.

Asphyxia, or suffocation, follows prevention of the due entry of oxygen into the blood, and its symptoms may be roughly divided into three stages. In the *first* the breathing becomes exaggerated (hyperpnea), then laboured and painful, inspiration, and later expiration, getting more violent; this brings the muscles of forced breathing into action, and the whole is due to the powerful stimulation of the respiratory centre by the increasingly venous blood. In the *second stage* the violent expiratory efforts become convulsive, and give way to general muscular convulsions, which arise from the further stimulation of the centres in brain and cord by venous blood. The convulsive stage is a short one, and lasts less than a minute. The

third stage is exhaustion.—In it the respirations all but cease, the spasms give way to flaccidity of the muscles, there is insensibility, the conjunctivæ are insensitive and the pupils are widely dilated. Every now and then a prolonged sighing inspiration takes place, at longer and longer intervals, until breathing ceases altogether, and death ensues. During this stage the pulse is scarcely to be felt, but the heart may beat for some seconds after the respiration has stopped. The condition is due to the gradual paralysis of the centres by the prolonged action of the venous blood. This stage may last three minutes and upwards. After death from asphyxia it is found that the right side of the heart, the pulmonary arteries, and systemic veins are gorged with dark venous blood, whereas the left side of the heart, the pulmonary veins, and the arteries are usually empty. The left ventricle undergoes early rigor mortis. In the first and second stages the arterial pressure rises, in the third stage it falls from heart failure, and the pressure in the veins then rises till death ensues: this is due to venous congestion.

INFERNAL OR TISSUE RESPIRATION.—This aspect of the subject we have long postponed. It is the utilisation of oxygen brought to the tissues, and the combustion that there ensues. Of the ultimate products, carbon dioxide and part of the water find their outlet by the lungs. We may begin by comparing the composition of the inspired or atmospheric air with that of expired air in the following table:

	Inspired Air.	Expired Air
Oxygen	20.96 vols. per cent.	16.03 vols. per cent.
Nitrogen	" " " "	" " " "
Carbonic acid	0.04 " "	4.1 " "
Water vapour	variable "	saturated "
Temperature	" "	that of body (37° C. or 98.6° F.)

The chief change is in the proportion of oxygen and carbonic acid. The loss of oxygen is about 5, the gain in carbonic acid about 4.5. If the inspired and expired airs are carefully measured at the same temperature and barometric pressure, the volume of expired air is thus found to be rather less than that of the inspired. The conversion of oxygen into carbonic acid would not cause any change in the volume of the gas; for a molecule of oxygen (O_2) would give rise to a molecule of carbonic acid (CO_2) which would occupy the same volume (Avogadro's law). It must, however, be remembered that carbon is not the only element which is oxidised. Fat and protein contain a number of atoms of hydrogen, which, during metabolism, are oxidised to form water; a small amount of oxygen is also used in the formation of urea. Carbohydrates contain sufficient oxygen in their own molecules to oxidise their hydrogen; hence the apparent loss of oxygen is least when a vegetable diet (that is, one consisting largely of starch and other carbohydrates) is taken, and greatest when much fat and protein are eaten. The quotient $\frac{CO_2 \text{ given off}}{O_2 \text{ absorbed}}$ is called the *respiratory quotient*. Normally it is $\frac{4.5}{5} = 0.9$, but it varies considerably with diet, as

just stated. The amount of respiratory interchange of gases is estimated by enclosing an animal of man in an air-tight chamber, except that there is a tube entering and another leaving it; by one tube oxygen or air can enter, and is measured by a gas-meter as it passes in. The air is drawn through the chamber, and leaves it by the other tube; this air has been altered by the respiration of the animal, and in it the carbonic

acid and water are estimated; it is drawn into bottles containing a known amount of an alkali such as soda-lime; this combines with the carbonic acid, and its increase in weight gives the amount of carbonic acid. The water is estimated in bottles containing pumice moistened with sulphuric acid.

Ranke gives the following numbers from experiments made on a man whose diet consisted of 100 grammes of protein, 100 grm. of fat, and 250 grm. of carbohydrate *per diem*. The amount of oxygen he used in the same time was 666 grm., of which 560 passed off as CO_2 , 9 in urea, and 97 as water. Vierordt gives the following average numbers: oxygen used per 24 hours, 744 grm.; this leads to the formation of 900 grm. of CO_2 and 228 grm. of H_2O . The respiratory exchange is lessened during sleep. In the winter sleep of hibernating animals the respiratory quotient may fall to 0.5. In muscular exercise the quotient rises, because there is increased combustion of glucose, the chief fuel in muscular energy.

External or pulmonary respiration is much less obscure than tissue or internal respiration, and we have treated it at considerable length. It must be borne in mind, however, that pulmonary respiration is but the means, and tissue respiration is the end. Tissue respiration consists in the passage of oxygen from the blood of the capillaries to the cells of the tissues, and the passage of carbonic acid in the reverse direction. This gaseous interchange is no doubt brought about by a simple process of diffusion. The oxygen passes out of the plasma of the blood through the capillary wall, and then through the lymph until it reaches the cell in which it is going to be used, which we will suppose is a muscle fibre. In order that a constant stream of oxygen may pass from the blood to the fibre there must be a difference of oxygen pressure between the oxygen dissolved in the plasma and that dissolved in the lymph, and the latter must be at a greater pressure than that dissolved in the muscle fibre. The amount of oxygen which passes will, other things being equal, be directly proportional to these pressure differences, and as the amount varies greatly at different times, it is obvious that the pressure differences vary greatly also. When the muscle is at rest, the oxygen pressure in the capillaries is very near to that in the muscle fibre; when the muscle is active and using large quantities of oxygen, the intra-capillary oxygen pressure is much greater than the intra-muscular oxygen pressure. Such a change might be brought about by a rise in the intra-capillary oxygen pressure, or a fall in the intra-muscular oxygen pressure, or by both taking place simultaneously. Let us therefore inquire what is known about these quantities. The tension of oxygen in muscle has been calculated as being at most equal to 19 mm. of mercury; from this it may vary down to zero. Within these limits the conditions for diffusion can be increased by a drop in the intra-muscular oxygen pressure.

There is, in addition, a mechanism for raising the intra-capillary oxygen pressure. This is the increased quantity of acid (carbonic and lactic acids) which is thrown into the blood as the result of muscular metabolism.

In glandular structures the oxygen pressure is higher than in muscle; they have a more copious blood supply, and equilibrium is more readily established. The quantity of oxygen used varies with the activity of the various tissues; weight for weight, glandular tissues use most oxygen, next comes muscle, and last connective and skeletal tissues. There are some tissues, notably the nervous system, about which we know but little in this connection. The amount of oxygen used by an organ or tissue per gramme per minute is called

its *coefficient of oxidation*. This is ascertained by (1) estimating the blood gases in the blood entering and leaving the organ, (2) determining the amount of blood passing through the organ in a given time, and (3) the weight of the organ investigated. The chief data are given in the following table:

Organ	Condition of Rest.	Oxygen used per minute per gramme of Organ	Condition of Activity.	Oxygen used per minute per gramme of Organ
orbital muscle.	Nerves cut. Tone absent.	0.003 c.c.	Tone existing in rest. Gentle contraction. Active contraction.	0.006 c.c. 0.020 c.c. 0.080 c.c.
striated muscle.	Resting.	0.004 c.c.	Contracting.	0.007 c.c.
heart.	Very slow and feeble contractions.	0.007 c.c.	Normal contraction. Very active	0.05 c.c. 0.08 c.c.
abdominal gland.	Nerves cut.	0.03 c.c.	Chorda stimulation.	0.10 c.c.
intestine.	Not secreting.	0.03 c.c.	Secretion after injection of secretin.	0.10 c.c.
pancreas.	Scanty secretion.	0.03 c.c.	After injection of ductin.	0.10 c.c.
intestine.	Not absorbing.	0.02 c.c.	Absorbing peptone.	0.03 c.c.
liver.	In fasting animal.	0.01 to 0.02 c.c.	In fed animal	0.03 to 0.05 c.c.
suprarenal gland.	Normal.	0.045 c.c.		

In all organs the table shows that increase of activity is accompanied by increase of oxidation. Much interest centres about the order of time in which these events occur. This matter has been investigated in organs (muscle and salivary glands) which can be thrown into great activity for a short time; in each case most of the oxidation follows upon the activity, and not the activity upon the oxidation. The important inference is drawn that the contraction or secretion, as the case may be, is not caused by the oxidation in the sense that the machinery of a locomotive is driven by the energy derived from the oxidation of the coal; rather is the mechanism like that of a spring which is liberated at the moment of doing the work, and has to be rewound subsequently; the process of rewinding involves oxidation. In muscle, the heat-formation which occurs in the period following activity only takes place if the muscle is supplied with oxygen. The output of carbonic acid, in its turn, follows upon the intake of oxygen. The order of events is therefore (1) increase of functional activity, (2) increase of heat formation and oxygen taken in, and (3) increase of carbonic acid put out. The increase of oxygen-consumption after the muscular contraction is over is called the 'oxygen-debt' (A. V. Hill and Lupton). This debt represents the oxygen used in oxidising the lactic acid formed.

The phenomenon of oxidation (auto-oxidation) in the body is one of the most important aspects of metabolism, and the fact that it occurs at the temperature of the body is not the least surprising circumstance. The recent discovery of a substance in the tissues by Sir F. G. Hopkins, termed *glutathione* (a compound of two amino acids, glutamic and cystine), is important. This is a catalyst which forms a most effective factor in the process.

Most of the figures relating to the gaseous metabolism were obtained by examining the organs of dogs. If the animal is weighed, and the composition of the inspired and expired air and the amount of oxygen taken in and given out determined, one

can calculate how much is retained and utilised. In the dog, the amount is about 0.016 c.c. of oxygen per minute per gramme of body-weight. This figure, however, is not the same in all animals, and the size of the figure will indicate what we may term the *intensity of respiration*. Thus in cold-blooded animals, especially fishes with their small

supply of oxygen, the figure is very much smaller. Among warm-blooded animals great variations are also seen; the intensity of respiration, for instance, is much greater in birds than in mammals. Among the mammals the intensity varies, roughly, inversely with the size of the animal; thus in the mouse, an animal that breathes with extreme rapidity, the intensity is probably ten to fifteen times greater than in the dog, in man the average is half that in the dog, and in the elephant very much less.

We will now discuss the conditions in oxygen-want. Normally a man takes into his blood 400 c.c. of oxygen per minute; this rises to 3000 according to the violence of muscular exercise. During contraction of a muscle the blood-flow through it is momentarily retarded; this produces oxygen-want there, and so leads to lactic acid production; the acid automatically relaxes the walls of the arteries, and so increases the blood supply. Exercise is the commonest cause of dyspnoea (distressed breathing). This breathlessness is not wholly produced by chemical changes in the blood, for it occurs before such changes take place, but is partly due to impulses from the motor cortex of the brain spreading to the medulla oblongata, and affecting the respiratory centre and causing acceleration of the heart, but after this the H-ion concentration of the blood produces its effect, as discussed under acidemia. Another cause of oxygen-want is diminution of the supply. This is best exemplified in *mountain sickness*, a disorder which attacks climbers (especially if untrained) at high altitudes. Its most obvious symptom is vomiting, which usually comes on at some spot where the ascent is particularly arduous, either by reason of the gradient or the wind. On the ascent of Monte Rosa from the Italian side there are three such spots, one at an altitude of 9000 feet, and the other two higher. Actual vomiting, however, does not always occur; often there are bad headaches, sleeplessness, absence of self-restraint, recklessness, irritability, and an inability to carry out the more complex cerebral functions, such as arithmetical calculations. Even without physical exertion it may affect a large proportion of people if the ascent is sufficiently rapid and the altitude sufficiently high. Thus, of the many who are suddenly transferred to the top of Pike's Peak in Colorado (14,000 feet) by rail from the lower country, few are well enough next morning to realise their ambition of seeing the dawn from the summit.

Adaptation to high altitudes consists in (1) increased pulmonary ventilation, (2) an increase in the hæmoglobin of the blood, and (3) at altitudes such as those of the mining towns in the Andes increased affinity of the red corpuscles for oxygen. A deficient supply of oxygen in the blood makes the respiratory centre more irritable and so produces

increased pulmonary ventilation, as shown by the following typical figures :

	Height of Barometer.	Respirations per Minute.	Litres Breathed per Minute.	c.c. per Breath.
Sea-level	760	17.1	10.4	614
Top of Pike's Peak	400	20.8	14.9	726

The respirations are increased both in rate and depth, and naturally deep breathers have an advantage at high altitudes over shallow breathers. The other important method is in the increase of coloured corpuscles and of hæmoglobin, and thus of the oxygen capacity of the blood, as shown by the following typical figures :

	Red Corpuscles per cubic mm. in Millions.	Oxygen Capacity of Blood
Sea-level	4.9	830 c.c.
After 1 week at 14,000 feet	5.4	870 c.c.
After 2 weeks	5.7	1040 c.c.
After 3	5.75	1060 c.c.

The same sort of adaptation occurs in airmen; and in animals increased activity of red marrow (the seat of red corpuscle formation), has been observed. It is, moreover, a matter of experience that from various causes an individual can do the same amount of muscular work, such as performing the same mountain-climb, with a less degree of metabolism after training. This is in part due to the fact that the trained person has lost unnecessary weight, and in part because he uses his muscles to better advantage. The reader interested in this question should get Professor Barcroft's book, *The Respiratory Function of the Blood*, part I. 'Lessons from High Altitudes' (Cambridge, 1925).

Let us now contrast with this respiration at high pressures.

Prolonged exposure to pressures of oxygen equal to 1300 to 1400 mm. of mercury, induces pneumonia, and death rapidly follows. It is not possible, therefore, for men to work in air which is compressed to the extent of producing so great a pressure of oxygen. But in the boring of tunnels and in carrying out operations in the beds of rivers it is usual to sink an iron tube in which the men work. This tube or caisson is closed except at the end at which the work is progressing, and the water is prevented from inundating it by pumping air into it at a pressure higher than that of the water. The men enter through a chamber with double doors or 'air-lock.' In this chamber the pressure can be raised or lowered. The pressure in the caisson rarely exceeds 4 atmospheres, which corresponds to about 600 mm. of oxygen; at this pressure the workers do not suffer whilst they are in the caisson, but grave symptoms may take place shortly after they have come out. Similar symptoms are experienced by divers who come to the surface from great depths. The symptoms may take the form of paralysis, vomiting, severe abdominal pain, vertigo, &c. They are due to the fact that the plasma, and indeed all the fluids which permeate the organs of the body, become saturated with oxygen and nitrogen at the pressure of the caisson, and therefore when the pressure is suddenly removed, minute bubbles form throughout the body and injure such tissues as the spinal cord, or produce blockage of the vessels. Short hours are necessary for caisson workers, for then the body has not time to get saturated with air at the caisson pressure, and in all cases 'decompression' must be gradual and slow; this gradual release from pressure is accomplished in the 'air-lock.' The dangers we have mentioned then cease to exist. The atmospheric gases are specially soluble in fat; fat people are therefore very susceptible to caisson disease, and should, in fact, be prohibited from labour in caissons.

Space does not allow of more than a reference to

the poisonous effects of many gases with which the Great War has made us familiar, but one gas only need be mentioned more fully, viz. carbon monoxide (CO). The fatal effects often produced by this gas (in accidents from burning charcoal stoves in small close rooms, or where there is an escape of coal gas) are due to its entering into combination with the hæmoglobin of the blood-corpuscles, and thus hindering their oxygen-carrying function. The affinity of hæmoglobin for carbon monoxide is much greater than its affinity for oxygen, and the compound formed—carboxyhæmoglobin—is much more stable than oxyhæmoglobin is. The only other form of abnormal breathing to which we will refer is known as *Cheyne-Stokes* respiration, which is so called after the two Dublin physicians whose names it bears. It is an exaggeration of the type of respiration often seen during sleep in perfectly healthy people, and after the winter sleep of hibernating animals. In it the breathing waxes and wanes to a remarkable degree, with pauses between the groups of pantings. It occurs in various diseases, especially as death is near, and is due to accumulation of acids (carbonic acid and lactic acid from oxygen-want): this goes on till enough is present to stimulate the respiratory centre; the panting gets rid of excess of carbonic acid, so that not enough remains to act as a stimulant and the series of events is repeated over and over again.

Historical.—Aristotle (384 B.C.) thought that the object of respiration was to cool the body. He observed that the warmer the animal the more rapid the breathing, and transposed cause and effect. Galen (131-203 A.D.) experimented upon the mechanics of respiration, and knew something of the nervous mechanism. He believed that 'snot' and water were excreted from the body by the lungs. Malpighi (1661) described the structure of the lungs. Van Helmont (1664) discovered carbonic acid; Black (1757) observed that carbonic acid is breathed out of the body. Priestley (1774) discovered oxygen. Lavoisier (1775) discovered nitrogen, found the composition of the air, and taught that the formation of carbonic acid and water resulted from the combustion that took place in the lungs. Vogel proved the existence of carbonic acid in the venous blood; Hoffmann found oxygen in arterial blood. Magnus extracted and analysed the gases of the blood in both states.

Comparative.—Most of the Protozoa, all the sponges and stinging animals, and many simple worm-types live in water, which washes their surface and saturates their substance, the oxygen dissolved in the water serving the same purpose as that mixed with the air. While many worms breathe simply through their skin, many of the aquatic forms have structures specialised for respiration—modifications of the legs or tentacles or vascular outgrowths of the body-wall. In echinoderms respiration is effected by the tube-feet, and sometimes by hollow 'skin-gills' as well. The crustaceans usually breathe by gills or through the skin; in insects air-tubes or tracheæ ramify throughout the body. Scorpions have plaited sacs or 'lung-books,' which are modifications of tracheæ; and these are developed in spiders also, with or, rarely, without the addition of ordinary air-tubes. The king-crab has 'gill-books,' adapted for breathing in water. Some molluscs breathe simply by the skin, others have external gills, most have gills sheltered by the mantle, and air-breathing forms like snails have a mantle-cavity which serves as a lung. In Balanoglossus there are numerous respiratory clefts opening from the pharynx to the exterior; Appendicularia and young tunicates have a pair of these; in adult tunicates the primitive clefts are replaced by numerous secondary slits

on the wall of the pharynx, through which water drawn in by the mouth passes into an atrial or peribranchial chamber and thence to the exterior; the same is true of Amphioxus. Clefts from the wall of the pharynx to the exterior are, indeed, characteristic of vertebrates, but beyond amphibians they are transitory embryonic structures, never used for breathing. This loss of functional gill-clefts is associated partly with the development of an embryonic birth-robe known as the allantois, which secures the aeration of the embryo's blood, and partly with the transition from aquatic to terrestrial life. In the hagfish the nasal sac opens into the mouth; in fishes this is only true of the double-breathing Dipnoi; in all other vertebrates an passes through the nostrils in and out of the mouth and lungs. In the hag and lamprey there are purse-like gill-pockets, and the respiratory arrangements are otherwise peculiar. In fishes gill-filaments are borne on the skeletal arches separating the gill-clefts, and the blood-vessels spread out on the filaments are washed by currents of water. Young elasmobranchs have at first external gills and afterwards the internal gills characteristic of all fishes. The Dipnoi have gills, but they also come to the surface and gulp air, using their air-bladder as a lung, and thus pointing the way to amphibians. For, while almost all amphibians have gills in their youth, all the adults are lung-breathers, though some retain their gills as well. Among higher vertebrates there are many peculiarities, such as the single lung of most serpents, the balloon-like air sacs around the lungs of birds, and the adaptations of cetaceans as aquatic lung-breathers, but the essential characteristics of pulmonary respiration are the same in all. The hemoglobin, so important in respiration, occurs first in nemerteans, and is present in some other worms, some echinoderms, a few arthropods, some molluscs, and in all vertebrates except the tunicates, Amphioxus, and a few exceptional fishes. Among invertebrates, the hemoglobin is as a rule not in special corpuscles but dissolved in the blood-plasma, and analogous pigments are not uncommon, especially one called hemocyanin, containing copper, not iron, which turns bluish when oxidised.

Respirators are worn over the mouth (oral) or mouth and nose (ori-nasal) for changing the properties of the air inspired. The name was first given by Mr Jeffreys to an apparatus he contrived about 1835 for the purpose of warming the air, formed of numerous layers of fine perforated metal with wire soldered to them. Respirators were much used formerly in diseases of the nose, throat, lungs, &c. for impregnating the inspired air with medicated vapours; for this purpose they were constructed with a chamber containing a sponge or cotton-wool which was kept charged with the substance whose action was desired (carbolic acid, creosote, eucalyptus, or pine-oil, &c.). Respirators have also been devised for freeing the inspired air of impurities—e.g. in the case of firemen, who have to go into an atmosphere strongly charged with smoke; of needle-grinders and others whose work gives rise to much irritating dust; of those who are exposed to foul gases, &c. They were habitually worn by the troops in the forward areas during the Great War in order to minimise the risk of poisoning by enemy gas. All the air inspired was drawn through an alkaline and oxidising powder which destroyed the gases, and the respirators were so comfortable that they could be worn for several hours at a time. See FILTER.

Respite, a temporary delay of the execution of a criminal. See REPRIEVE.

Respondentia is a loan raised by the master of a ship, when he has no other means of doing so, upon security of the cargo or goods on board the ship. The contract has reference to a particular voyage, and the conditions are that if the subject on which the money is advanced be lost by sea-risk, or superior force of the enemy, the lender shall lose his money; and that if the goods arrive in safety the loan shall be repaid with a greater than ordinary rate of interest, called marine interest. When the ship herself is hypothecated the contract is called *Bottomry* (q.v.). The lender of money on respondentia or bottomry has an insurable interest in respect of the loan.

Responsibility. See INSANITY, INFANT, HUSBAND AND WIFE, EVIDENCE, CAPACITY (LEGAL), MASTER AND SERVANT.

Responsions. See OXFORD.

Rest-harrow (*Oenonis*), a genus of plants of the family Leguminosae, sub-family Papilionaceae, having a 5-cleft bell-shaped calyx, the standard of the corolla large and striated, the keel beaked, the pod turgid and few-seeded. There are many species, chiefly natives of Europe, and generally herbaceous or half-shrubby. The Common Rest-harrow (*O. arvensis*) is abundant in pastures and by waysides in Britain. Its lower leaves have three leaflets, the upper are simple; the flowers are axillary and rose-coloured, or occasionally white. The plant is half-shrubby, with somewhat spiny stems; viscid; and its smell strong and unpleasant. The roots are tough and woody, whence its English name. It is sometimes a troublesome weed, but only in neglected pastures, and disappears before careful cultivation.

Restigouche, a river of Canada, rises in eastern Quebec, flows south-east into New Brunswick, then east and north-east into the Bay of Chaleurs, forming part of the boundary between the two provinces. Its length is about 200 miles.

Restionaceae, a family of monocotyledonous plants, mostly natives of the southern hemisphere, abounding at the Cape of Good Hope and in Australia. They are herbaceous plants, or sometimes half-shrubby, have simple stems and narrow leaves, and are hard, wiry, and rush-like. They have generally a creeping root stock.

Restoration, the resumption of monarchical government on the return of Charles II. to his kingdom, May 29, 1660. A form of prayer for that day was annexed to the Common Prayer-book from then until 1859; and, in commemoration of Boscobel (q.v.), 'Oak-apple Day' was long also celebrated by the displaying and wearing of branches and sprigs of oak, with gilded oak-apples.

Restoration, in its true sense, means bringing back or replacing what has gone; but the word has come to mean making new initiative work to take the place of decayed or fractured work, and in this sense it applies to pictures, sculpture, furniture, and architecture; but as applied to architecture it is allowed a still wider meaning—viz. the building up anew and with new materials of portions of buildings which have ceased to exist, such new work being designed afresh in imitation of what was supposed once to have existed.

In architecture an impulse was given to the restoration movement by a society called the Camden Society, and afterwards the Ecclesiological Society, which was composed of churchmen and clergy, and started at Cambridge in the year 1840. Our mediæval churches are generally composed of two or three and sometimes of all the styles; but the Gothic revivalists desired to see the buildings complete in one style, and consequently, if an ancient building were composed chiefly of one style, they would destroy all the subsequent work

and replace it by work designed in the same style. The subsequent work thus destroyed is generally spoken of as 'debased' work. Each one of the styles was in fashion in its turn, strangely enough each becoming fashionable in the order in which they were naturally developed. As might be expected, the movement produced specialists, of whom Sir George Gilbert Scott was the most noted. Into his hands was placed nearly every cathedral church in England, as well as a countless number of parish churches; however, he did but follow in the steps of the elder Pugin. Long before his death a cry of discontent arose. Even those who had felt that it might be possible to imitate the mediæval work accurately, so as to replace missing features, saw that this was a hopeless task, for not a single successful example of 'restoration' could be pointed to. Ruskin wrote strongly against 'restoration,' urging the folly of attempting to reproduce a lost work of art or any portion of it, and giving it as his opinion that the only right method of treating our ancient buildings—such indeed as had not been destroyed by 'restoration'—was to repair them structurally by propping leaning walls and mending leaky roofs. His words did but sound the note which was in the minds of many, and in 1877 was founded in London the Society for the Protection of Ancient Buildings, and restoration as understood by the school of Sir Gilbert Scott is now ancient history.

Restoration of Pictures. The restoration and the cleaning of pictures may be considered together: though cleaning, of course, more strictly applies to the removal from their surface of the accretions of dust or discoloured varnish which obscure their beauties, while restoration refers to the reparation of actual flaws in their surfaces of paint, or in the canvas or wood upon which the paint is laid. When a mastic varnish has been used by the painter, and has become discoloured and opaque, it may be removed by careful and gentle friction with the points of the fingers, previously covered with a resinous powder, which frays off particles of the hardened coating in the form of a fine white dust. When copal varnish has been applied, its removal is more difficult and dangerous, and is usually effected by an application of weak alcohol, spirits of turpentine, and oil. A pad of cotton wool is saturated in this mixture, and passed over the surface of the varnish, which it dissolves and removes; a similar pad steeped in pure oil being applied at intervals to stop the action of the spirit when it threatens to disturb the colour beneath the varnish. When portions of the paint or of the ground of priming on which it has been laid have been removed, these are sometimes filled up to the level of the remaining portions with glue, size, and chalk, and then carefully repainted with dry colour to match the surrounding portions of the surface.

The injuries of time to the various materials upon which colours are laid are very various, and require careful and skilful treatment. In panel pictures worm-holes must be carefully filled up with the last-named composition, and matched with the adjacent portion as just described. If the wood has split, its edges must be carefully brought together, and fastened securely with 'buttons' of hard wood; or the entire back may be protected with a kind of grating of mahogany spars, so adjusted as to admit of a slight contraction and expansion of the panel in varying temperatures. If the panel be too far gone to admit of this treatment, the wood is carefully removed by tenon-saws, planes, and files, till only the surface of priming and colour remains, which can then be remounted on canvas or a fresh panel. If the picture is on canvas which has become decayed, it may be

'relined' by having its back securely fastened, by paste or glue, to a new canvas, and afterwards ironed, a process which has the effect of restoring evenness to a cracked surface of paint; though if the artist has worked with a thick impasto the raised points of colour are apt to become flattened, and the character of the handling to be slightly altered. When a fresco has to be removed from a wall this is usually effected by pasting its surface on paper, and then with a chisel slowly detaching the mortar which bears the colour from the stones upon which it has been laid, each portion, as it is gradually withdrawn, being coiled on a large cylinder. All the operations to which we have referred require extreme caution and great practice for their successful accomplishment. When they are entrusted to careless and untrained hands damage is certain, and it is impossible to estimate the immense amount of injury to works of art that has been effected by ignorant picture-restorers. Proper care of a picture, however, and preservation from damp and dust, will obviate the necessity for its being subjected to restoration; and such protection may be most simply effected by carefully closing in its back, and by covering its surface with glass, which answers all, and more than all, the preservative purpose of varnish, with the additional advantage that it does not chill and discolour with time. Glass is being largely adopted in the great public galleries, for covering even oil-pictures, and it has only one disadvantage—its tendency to reflect the objects placed opposite it, and so to interfere with the ready and complete examination, as a connected whole, of the entire surface of a large, and especially of a dark, painting.

Restorationists, a general name for those who hold the belief in a general *apocatastasis*, or 'restoration' of all things, in which, after a purgation proportioned to the various moral conditions of their souls at the time of death, all men would be restored to the favour of God. The title itself is especially associated with a body of Universalists which flourished at Boston, U.S.A., in the first half of the 19th century; but for the doctrine, see HELL and UNIVERSALISTS.

Resurrection, the revival of the human body in a future state after it has been consigned to the grave. We find traces in Zoroastrianism, and especially in later Judaism, but the doctrine is more characteristically Christian. In the earlier Hebrew Scriptures there is no mention of it. It is not to be found in the Pentateuch, in the Psalms, nor even in the earlier prophecies. It is supposed to be alluded to in Isaiah (xxvi. 19), and in Ezekiel (xxxvii.) in the well-known chapter as to the revival of dry bones in the valley of vision; and in the last chapter of Daniel (xii. 2) there is the distinct affirmation that 'many that sleep in the dust of the earth shall awake, some to everlasting life, and some to shame and everlasting contempt.' There is also a well-known passage in Job (xix. 25-27) which was long thought to refer to the doctrine of the resurrection of the body; but all recent criticism denies the validity of this reference. It is therefore not till the later Judaism that the doctrine appears, and it is sometimes said, doubtfully, to have been derived from Persia or elsewhere. In the time of Christ it had become a formal doctrine of the Pharisees. The general body of the Jewish people seem also to have believed in it; the Sadducees alone disputed it. It appears, in fact, to have become bound up in the Jewish mind with the idea of a future life, so that an argument which proved the one proved the other. It should be added that Mohammedanism (q.v.) cherishes gross beliefs on this head.

The Gnostics denied the resurrection of the body,

and made the change a purely spiritual one. The Catholic belief was greatly developed by Tertullian, Jerome, and Augustine, who, however, insisted that the resurrection body, though identical with the original one, is a glorified body. A third view, represented by Origen, affirms that the spirit must always have a bodily organism, and that the perfected personality necessarily assumes a spiritualised embodiment; in this view resurrection is limited to perfected spirits.

See the articles IMMORTALITY, CONDITIONAL IMMORTALITY, HEAVEN and HELL.

Resurrectionists, or **BODY-SNATCHERS**, the names popularly given to those who made it their business to dig corpses out of their graves and sell them as 'subjects' to lecturers on anatomy. From about the middle of the 18th century the supply of subjects, heretofore mainly obtained from the bodies of executed criminals, was altogether inadequate. The resurrectionists invented a new profession to supply the lack, and in the first quarter of the 19th century drove a most flourishing trade. An expert pair of resurrectionists in about forty-five minutes could prise up the coffin out of a newly-made grave by means of a peculiar crowbar for the purpose, burst in the lid, and remove the corpse. They carefully replaced the clothing in the coffin; the stealing of the naked corpse being by the law of England a misdemeanour only, the removal of the clothes was a felony, punishable by transportation. Painful precautions against body-snatching were taken. Heavy gratings were securely fixed over new-made graves, spring-guns were set, and often the relatives of deceased persons sat armed by their graves night after night until it was assumed that the corpses would be no longer servicable to 'the doctors.' Guard-houses or towers were sometimes built for the accommodation of the watchers. To the popular horror was added a strong suspicion that resurrectionists would on occasion manufacture corpses—a suspicion confirmed in the notorious case of Burke and Hare (see BURKE, WILLIAM). The Anatomy Acts of 1832 and 1871 rendered the trade of the resurrectionist superfluous.

Retainer is, in English law, the act of engaging an attorney or counsel to attend to a certain suit or case. The retainer of an attorney may be either verbal or in writing; but the retainer of counsel is usually by written memorandum handed to his clerk, together with a small retaining fee. A general retainer is given by a party who wishes to secure the services of counsel in all actions brought by or against him. The term retainer is also used to denote the right of an executor to retain a debt due to himself from his testator's estate.

Retford, EAST, a town of Nottinghamshire, on the right bank of the Idle, an affluent of the Trent, 24 miles E. by S. of Sheffield. It has a handsome town-hall (1867), a grammar-school (1552; rebuilt 1858), paper-mills, iron-foundries, &c. It was first formally incorporated by James I. Pop. of municipal borough (1851) 2943; (1891) 10,603; (1921) 13,412.

Retimo (*Rithymnos*), a seaport of Crete, on its north coast, 40 miles W. of Candia; pop. 7000.

Retina. See EYE.

Retinite, a variety of amber; formerly also a name for Pitchstone (q.v.).

Retinospora. Some species of Juniper, Cupressus, Chamaecyparis, &c., vary their foliage, the juvenile stage being followed by a second and third stage. The juvenile stages can be perpetuated, and were in this form largely brought from Japan into European gardens. Their origin being

unknown, they were thought to belong to one genus only, which was called *Retinospora*. When it became known that these mysterious trees and shrubs were but growth-forms of different coniferous genera, *Retinospora* fell, *ipso facto*, to the ground for botanical science, but it lingers in gardens.

Retired Pay. See PENSIONS.

Retort, a vessel employed by chemists for the purpose of distilling or effecting decomposition by the aid of heat. It may be made of glass, earthenware, or metal, according to the purposes for which it is to be employed. Glass retorts are the most common, and their ordinary form is seen in the figure. They may be employed for the production

Retort fitted with Liebig's Condenser:

A, bulb of the retort, into which the liquid to be distilled is put; D, the receiver, into which the end of the retort is placed; BB, the condenser, receiving a supply of cold water from E by means of the pipe C, the heated water escaping at F; G, the heating apparatus, a Bunsen burner in this case.

of such products as do not require any extraordinary degree of cold for the condensation of their vapour—as, for instance, for the production of hydrocyanic or nitric acid. The globular vessel in which the neck of the retort is inserted is from its function termed the *receiver*. Cold may be applied to the neck of the retort—for the purpose of condensing the vapour—in various ways, as by the application of a cold wet cloth, by a current of water, or by a special apparatus known as *Liebig's Condenser*, shown in the figure at BB.

In ordinary cases requiring a higher temperature than glass could bear earthen retorts are used; for the preparation of hydrofluoric acid retorts of lead are employed; while for the preparation of strong sulphuric acid platinum is the best material for the retort. Iron retorts are employed in the laboratory for the preparation of oxygen from black oxide of manganese and some other processes, and in gas-works for the destructive distillation of coal. See DISTILLATION.

Retours. See RECORDS (*Scotland*).

Retreat, a period of retirement to a religious house, for self-examination, meditation, and prayer. Retreats commonly last either three or seven days, and are conducted by a cleric, who delivers addresses daily. They are in use both in the Roman and, among the High Church party, in the Anglican Church.

Retriever. As the name implies, the retriever is a breed of dog trained to find out and bring back any killed or wounded game. The work of the retriever was long done by various breeds of dogs, such as the pointer, setter, or spaniel, but, in addition to it spoiling these dogs for their regular work, they were found to be too hard-mouthed, the worst fault possible in a retriever, as he wastes more in game injured than would have been lost

without him. Crosses with the Newfoundland were tried, and gradually two kinds of retriever were introduced. One variety, known as wavy-coated, was probably the result of a cross with the setter; the curly-coated is from the water-spaniel or poodle.

Retrograde, in Astronomy, a term applied to the motion (real or apparent) of a celestial body when that is opposite in direction to the yearly course of the sun from west to east. The superior Planets (q.v.) retrograde when in opposition (see CONJUNCTION). As their motion is then nearly parallel to the earth's, they, moving more slowly than it, appear to *fall behind* for a time. This period of retrogradation is of course longer for the planets whose motion is slower, and less for those whose speed more nearly approaches that of the earth. The inferior planets, which move faster than the earth, retrograde when in inferior conjunction. Their course being then nearly parallel to the earth's, they gain upon it, and appear to pass the sun from east to west. Thus Venus, when nearing the end of her appearance as an evening star, descends each night nearer to the western horizon, until so near the sun as to be lost in his rays. Passing then to his west side, the planet reappears as a morning star.

RETZ, JEAN FRANÇOIS PAUL DE GONDI, CARDINAL DE, was born at Montmirail in 1614, of a family originally Italian, that had acquired great estates in Brittany and formed connections with the noblest families of France. His uncle was Archbishop of Paris, and he was early destined for the church in spite of amours, duels, and every form of unclerical behaviour. A friend reproaching him with his debts, 'César,' said the splendid young prodigal, 'at my age owed six times as much as I do.' Retz was entangled in political intrigues from his childhood up, even under the watchful eye of Richelieu, and, having at length in 1643 obtained the coadjutorship with reversion of the archbishopric of Paris, he skillfully used the position to make the Paris populace devoted to himself. He plotted actively against Mazarin, and was one of the main instigators of the outbreak of the Fronde in October 1648. During the next four years he rose and fell with the fortunes of his party, receiving, however, a cardinal's hat from Rome, until 1652, when he was flung into prison, first at Vincennes, then at Nantes. After two years he made his escape, wandered in Spain and England, appeared at Rome—where, it is said, he secured the election of Pope Alexander VII.—and at length in 1662 made his peace with Louis XIV. by resigning finally his claim to the archbishopric in exchange for the abbacy of St Denis and restoration to his other benefices, with arrears. He spent the rest of his life mainly in quiet at Paris, at Commercy, and St Mihiel in Lorraine. His enormous debts, reaching to four millions of francs, he provided for in 1675 by determining to 'live for his creditors,' making over to them his whole income save 20,000 livres. He died at Paris, 24th August 1679.

Retz was connected by marriage with Madame de Sévigné, and figures in a perhaps too pleasing light in her delightful letters. His *Mémoires*, coming down but till 1655, throws much light on the dark and troubled intrigues of the Fronde, and displays quite remarkable skill in narrative and elaborate character-drawing. His own character has been sketched with faithful, if unkindly, truth by his great antagonist, La Rochefoucauld, and the sum of the whole is contained in the words: 'He has raised up the greatest disorders in the state without having formed any plan how to profit by them.'

The earliest edition of his masterpiece in a kind peculiar to French literature appeared at Nancy in 1717, but the first adequate edition was given in the 24th vol. of Michaud and Poujoulat's collection (Paris, 1836). Later and better editions are by Gêrueux (1844) and Champollion-Figeac (1859); but the best is that in the series of 'Les Grands Écrivains de la France,' edited successively by A. Feillet, J. Gourdault, and R. Chantelauze (10 vols. 1872-90). See works by Curnier (1863), Topin (3d ed. 1872), Chantelauze (1878-79), Gazier (1876), and D. Ogg (1912).

RETZ, RAIS, or RAIZ, GILLES DE, a 15th-century monster of iniquity, was a Breton of high rank and family connections, who distinguished himself under Charles VII. in the struggle with the English, fighting by the side of the Maid at Orleans, and bearing the alms-dish at the coronation. Born in 1404, he was made marshal of France at twenty-five, but soon retired to his estates, where for over ten years he is alleged to have indulged in the most infamous orgies, having kidnapped or enticed to his castle as many as 150 children, who were sacrificed as victims to his unnatural lusts or his sorceries. He was at length hanged and burned at Nantes in 1440, after a trial closed by his own confession. It should be noted that the whole story is by no means free from suspicion, and, moreover, that both the Bishop of Nantes and the Duke of Brittany were active personal enemies of Retz. Attempts have been made to find in him an historical original for 'Bluebeard' (q.v.) by persons ignorant of the world-wide diffusion of stories of forbidden chambers and punishments for curiosity. See Vincent and Binns, *Gilles de Rais* (1926).

RETZSCH, FRIEDRICH AUGUST MORITZ, painter and engraver, was born in Dresden, 9th December 1779, and studied at the academy of his native city, where he became a professor in 1824. He died 11th June 1857. He has acquired great celebrity by his etchings in outline of Schiller and Goethe—those of Goethe's *Faust* being particularly well known—Fouqué's tales, and Shakespeare. His masterpiece is 'The Chess-players' (Man against Satan). Retzsch likewise painted admirably in oils.

Reuchlin, JOHANN, also known by his Greekised name of *Capua*, humanist and one of the first promoters of Hebrew studies in Germany, was born at Pforzheim in the Black Forest, 28th December 1455. He received his earliest education at Schlettstadt, and in 1473 was appointed travelling companion to Prince Friedrich of Baden. In this capacity he visited Paris, where he studied Greek under Hermonymus of Sparta, besides assiduously practising the composition of Latin. Two years later Reuchlin went to Basel, where he continued his study of Greek, and wrote his Latin dictionary, *Vocabularius Breviloquus* (1476). In the same year he paid a second visit to France, studied law at Orleans (1478) and at Poitiers, then, returning to Germany (1481), set up as lecturer at Tübingen. In 1482 and again in 1490 he was in Italy on the business of Duke Eberhard; in 1492 we find him studying Hebrew under a learned Jew, Jacob Jehiel Loans, the imperial physician. In 1496 Reuchlin went to Heidelberg, where he became the main promoter of Greek studies in Germany, though not a public lecturer. In 1498 he was sent to Rome by Philip the Elector-palatine, and applied himself more vigorously than ever to the study of Hebrew and Greek. Reuchlin returned to Stuttgart in 1499, and in 1500 obtained a judicial appointment. In 1506 appeared his *Judamenta Lingue Hebraica*. His Hebraic studies, which embraced the post-biblical Jewish literature, were drawing him into bitter strife with learned Jews, Jewish proselytes, and the Dominicans, and directly and powerfully helping on the Reformation. It was in 1510 that Johann Pfefferkorn, a Jewish proselyte, in the

true spirit of a renegade, called upon princes and subjects to persecute the religion of his fathers, and especially urged the emperor to burn or confiscate all Jewish books except the Bible. Reuchlin remonstrated, maintaining that no Jewish books should be destroyed except those directly written against Christianity. This tolerant attitude drew upon Reuchlin the enmity of the Dominicans, and particularly the inquisitor, Jakob von Hoogstraten. These enemies of Reuchlin held possession of the universities of Paris, Louvain, Erfurt, and Mainz; but all the distinguished and independent thinkers in Germany were on the side of the brave and humane scholar. Among the Reuchlinists we may especially mention the names of Ulrich von Hutten (q.v.) and Franz von Sickingen (q.v.); and to this controversy we owe the *Epistole Obscurorum Virorum* (q.v.). A quarrel broke out between Ulrich Duke of Wurttemberg and the Swabian League, in the course of which Reuchlin became a prisoner of Duke Wilhelm of Bavaria, who, however, in 1520 appointed him professor at the university of Ingolstadt. In 1522 the plague broke out at Ingolstadt, and Reuchlin taught once more for a term at Tübingen, but soon after fell sick and died at Liebenzell, near Hirschau, on the 30th of June.

Reuchlin edited various Greek texts, published a Greek grammar, a whole series of polemical pamphlets, and a satirical drama (against the Obscurantists), and in *De Verbo Mirifico* and *De Arte Cabalistica* shows a theosophical-cabalistic tendency. See Lives by Barham (Lond. 1843); Geiger (1871); Horowitz (1877); a work on him by Holstein (1888); and W. S. Lilly's *Renaissance Types* (1901).

Reumont, ALFRED VON, German historian, was born at Aachen on 15th August 1808, and died there on 27th April 1887, having from 1829 to 1860 followed a diplomatic career, chiefly in Italy. His numberless works deal mainly with Italian history, and one of the best known, his *Lorenzo de' Medici*, appeared in English in 1876.

Réunion, formerly called ÎLE DE BOURBON, an island belonging to France, lying in the Indian Ocean, 115 miles SW. from Mauritius and 350 E. from Madagascar. An ellipse in shape, it has an area of 764 sq. m., being 38 miles in length and 28 in breadth. Population, 174,000, mostly white. The backbone of the island is a volcanic range, culminating in two higher peaks, the Piton des Neiges (10,069 feet) in the centre of the island, and in the south-east Piton de la Fournaise (8612 feet), one of the most active volcanoes in the world. The central parts of the island between these volcanic peaks consist of plateaus and terraces, separated by deep cauldron-shaped valleys and narrow, but profound, gorges and ravines. Piton de la Fournaise is surrounded by a vast dreary desert called the *Pays Brûlé* ('Burnt Land'). Except in the mountainous parts the soil is in general very fruitful. The scenery is often beautiful. Streams, although not large, are very numerous, and fall in cascades to the sea. The climate is hot, but on the whole not unhealthy. Rainfall averages 45½ inches in the year. Cyclones sometimes occur during the hotter and rainy part of the year (November to April), and high spring-tides occasionally do serious damage during the remaining drier months. One-third of the island is cultivated, one-third under timber, and one-sixth is grass-land. Tropical fruits, sugar (the staple crop), coffee, vanilla, cinchona, maize, vegetables (potatoes, &c.), spices, tobacco, and similar products are grown. By far the most important export is sugar; others are coffee, vanilla, rum, potatoes, and tapioca. The capital is St Denis, on the north coast, with 21,500 inhabitants, a college, a botanic garden, &c.; it is a bishop's seat. The remaining towns are St Paul, on the north-west,

with 19,000 inhabitants, and with marine workshops; St Pierre, on the south-west coast, pop. 28,000; Pointe des Galets, a port between St Denis and St Paul; Salazie, with warm mineral springs, a health-resort; and St Louis. The coast towns are connected by a railway 78 miles long. The colony is administered by a governor and an elected council. Réunion and Mauritius were discovered by the Portuguese navigator, Mascarenhas, and named after him the Mascarene Isles. The French took possession of this island in 1649, and called it Bourbon, which was changed to Réunion at the Revolution, and to Ile Bonaparte in 1809. Réunion has been the official name since 1848. The island was in the possession of Britain from 1810 to 1815.

Re'us, a town of Spain, 58 miles by rail SW. of Barcelona. Its prosperity dates from about 1750, when a number of English merchants settled there. It is a busy centre of the cotton, silk, and silk-jibbon industries, and manufactures wool, soap, brandy, and leather. Pop. 30,000.

Reuss, a tributary of the Aar in Switzerland, rises on the northern face of the St Gothard, flows northwards past Andermatt and Amsteg, between which places its bed lies at the bottom of a wild and narrow gorge, spanned by the Devil's Bridge and other wonders of Swiss roadmaking, and enters the southern end of the Lake of Lucerne. This it leaves again at its north-western end, at the town of Lucerne, and, again going nearly due north, reaches the Aar near Windsch (Aargau). Its length is 90 miles; its basin, 1317 sq. m.

Reuss, the name of two former principalities of Germany, lying between the republic of Saxony on the E., Prussian Saxony on the N., and Bavaria on the S. The principality of Reuss-Greiz (the Elder Line) was 122 sq. m. in extent. The chief town was Greiz (q.v.). The principality of the Younger Line was Reuss-Schleiz-Gera; area, 319 sq. m.; capital, Gera. The surface is hilly, being traversed by the Frankenwald (Thüringerwald), whose summits reach upwards of 2000 feet in height. The chief rivers are the Saale and the White Elster, the valleys of which are well cultivated. More than a third is covered with forests; cattle are fattened on the extensive meadows; and woollen, cotton, and silk goods are woven. The reigning prince of each state was a hereditary sovereign, and always bore the name of Heinrich. The two principalities became republics in 1918, united in April 1919, and in December Reuss and other states united to form the republic of Thuringia (q.v.).

Reuter, FRITZ, German humorist, was born at Stavenhagen ('Stemhagen') in Mecklenburg-Schwerin, on 7th November 1810. His father, the burgo-master, sent him to Rostock and Jena to study law. But in 1833 he was arrested and condemned to death—in common with other members of the *Jena Burschenschaft* (q.v.) *Germania* he had indulged in wild students' talk about the fatherland and national unity; that was his only offence. The capital sentence was commuted to one of thirty years' imprisonment. Young Reuter was dragged from one fortress prison to another in Prussia and Mecklenburg, and often subjected to great hardships and even wanton cruelty, and did not regain his freedom until Frederick-William IV. ascended the throne of Prussia in 1840. Although a general amnesty gave him back his liberty after seven years of imprisonment, his career was spoiled and his health incurably ruined; an affection of the stomach created in him an abnormal craving for strong drink, which he never conquered. It was eleven years more before he settled down to his

life's work. His father, a stern and severe man, having in the meantime turned his back upon him as a good-for-nothing, he tried to resume his legal studies, learned farming, taught pupils, but lived chiefly on the kindness of a friend and on a small annuity left him by his father, who died in 1845. Reuter began to write first in High German; but having thrown into rough verse form, in Low German, the jokes and merry tales of the countryside, he published them—*Lauschen un Rümels* (1853), and the book became at once a great favourite with all who spoke and read Low German. Two years later he wrote an equally successful Low German poem, *Reis' nah Belligen*, describing in broad humorous fashion the journey of certain peasants to Belgium in search of culture. The next seven years (1856-63), passed at Neubrandenburg, were the period in which he wrote his greatest books. The first of these were a second volume of *Lauschen un Rümels* (1858), and the deeply tragic poem *Kein Husung* (1858), picturing the wretchedness of the semi-serfs on the great Mecklenburg domains. The rest, except *Hanne Nute* (1860), a poetic narrative in which birds figure prominently as speaking characters, were all written in prose in Low German (*Platt-Deutsch*), and were published under the general title of *Olle Kamellen*, which may be given in English as *Old-time Stories*. These books, more especially *Ut de Franzosentid* (1860; Eng. trans. as *The Year '13*, 1873), *Ut mine Festungstid* (1862), and his masterpiece, *Ut mine Stromtid* (1862-64), spread Reuter's fame abroad through all Germany, and lifted him to the proud position of Germany's greatest humorist next after Jean Paul; as a literary artist he ranks in many respects above Jean Paul. These tales have the indubitable flavour of real life: they deal with the characters and doings of rural Mecklenburg, are told with the verve of the born story-teller, and are bathed in the purest and sunniest humour. Like every true humorist, Reuter is master of a tender pathos. Uncle Bräsig in *Stromtid* is one of the greatest creations of German literature. The best witness to Reuter's own character is the history he wrote (*Ut mine Festungstid*) of the miserable seven years he spent in prison: the book has not one word of bitterness or a single trace of revengeful feeling throughout; good-nature and humour are its dominant notes. Besides the works quoted, Reuter also wrote *Schwur Murr* (1861), sketches of country life, partly autobiographical; *Dorchtauchting* (1866), a kind of humorous historical novel; the satirical *Ungeschicht von Mecklenburg* (1874), and others. Reuter lived at Eisenach in Thuringia, at the foot of the Wartburg, from 1863 till his death on 12th July 1874.

His *Sammtliche Werke* were published in 13 vols. at Wismar in 1863-68; to these Adolf Wilbrandt added two more in 1875, together with a biography. There have been several editions since—one by Müller in 19 vols. in 1905; and lives or books about him by Glagau (2d ed. 1875), Elbert (1874), Gaedertz (1890, 1900, 1905), Naatz (1895), and Brandes (1899). See collections of his letters published in 1895 and 1909.

Reuter, BARON PAUL JULIUS DE, was born at Cassel, 21st July 1821. In Aachen he formed in 1849 an organisation for collecting (partly by pigeon post) and transmitting by telegraph commercial and financial news; and in 1851 he transferred his headquarters to London. As telegraphs extended throughout the world he multiplied the ramifications of his system till it embraced the remotest regions. He even maintained couriers where the telegraphs did not reach—e.g. between Peking and Kiakhta. In 1865 Reuter converted his business into a limited liability company, and in 1871 he was made a

baron of Saxe-Coburg-Gotha. In 1872 the Shah of Persia gave him the sole right of making railways, working mines, forests, &c.—a monopoly never made effective, and annulled in 1889, when the concession of the Imperial Bank of Persia was conferred on him. He died 22d February 1899. For the development of 'Reuters' see H. M. Collins, *From Pigeon Post to Wireless* (1925).

Reutlingen, a town of Württemberg, 8 miles E. by S. of Tübingen and 20 S. of Stuttgart. Many of its houses are old and picturesque. The church of St Mary (1247-1343), with a tower 243 feet high, is a noble Gothic edifice. Woollen and cotton yarns are spun, and cloth, leather, cutlery, hosiery, paper, &c. are manufactured. Reutlingen was formerly a free imperial town and a member of the Swabian League; it came to Württemberg in 1802. Pop. 30,000.

Reval, or REVEL (Est. *Tallinn*), a Baltic seaport, capital of Esthonia, stands on a small bay on the south side of the Gulf of Finland, opposite Helsingfors (52 miles distant), and 232 miles by rail WSW. of St Petersburg. It is divided into the (old) upper and (new) lower towns. The former (Domburg) contains the cathedral and the castle. The new town extends outside the city walls. There are several mediæval guild-houses with valuable archives, an important museum of antiquities, and a palace built for Catherine by Peter the Great. The Church of St Olaf has a tower 463 feet high. Reval exports grain (wheat, oats, rye, barley) and flax, veneer and joiner's work, asbestos, mineral oil, glycerine, hides, &c.; and imports manufactured goods, coal, &c. Pop. (1922) 122,419. Reval was founded by Waldemar II. of Denmark in 1219, and became a flourishing Hanse town. It was long held (from 1346) by the Livonian Knights, was made over to Sweden in 1561, and was besieged by Peter the Great and annexed to the Russian empire in 1710. In 1713 a naval harbour was founded.

Revalenta Arabica. See LENTIL.

Reveillè (the true French form being *réveil*), the morning call for troops. See BUGLE.

Revelation is a familiar theological expression, properly used of all divine knowledge communicated through whatever source. Conscience and reason are in themselves modes of revelation, in so far as they witness to us of the divine laws which bind our moral life, and in harmony with which the health and happiness of that life can alone be found. History is also a species of revelation, unfolding, as it does, the same divine laws collectively in the race. Then nature reveals the divine power, wisdom, and goodness; and science, the interpreter of nature, in so far as it makes known the great laws governing the material universe, truly makes known the divine will to us. But it is with the Scriptures of the Old and New Testament that the idea of revelation has come to be especially associated. These books, however, are only the highest or most distinguished form or medium of revelation. They contain a revelation for us; but the revelation is not the record, but the knowledge which the record conveys to our minds. See BIBLE, INSPIRATION.

Revelation, BOOK OF, the last book of the New Testament canon. It is also called the Apocalypse, and belongs to the class of writings known as Apocalyptic. Apocalyptic literature is peculiar to the Jewish people. It began with the Book of Daniel, though Apocalyptic elements are found in Ezekiel and some of the older prophets, and flourished in the intermediate period between the Old and New Testaments. Among the most important Apocalypses may be mentioned the

Book of Enoch, the Apocalypse of Baruch, the Assumption of Moses, the Ascension of Isaiah, and the fourth Book of Ezra, which is probably almost contemporary with our Book of Revelation. The leading ideas of Apocalyptic are: (1) The belief in the near approach of the Day of the Lord, when the kingdom of saints would be set up on earth; (2) The vindication of God's own people, who are to receive supremacy over the nations of the earth; (3) The execution of a terrible punishment upon their enemies and persecutors; (4) The belief that the pious dead would rise to partake in the triumph of God's people. (5) Linked with this belief in the establishment of the Kingdom of God on earth was the conviction that in the future life good men would be rewarded and compensated for their sufferings, and had men would receive punishment for their crimes and sins.

The book of Revelation is an attempt to combine these Apocalyptic ideas with the Christian faith. It must always be open to question, however, whether in the book of Revelation it is Christianity that has captured Apocalyptic or Apocalyptic that has captured Christianity.

Circumstances under which the Book was written.

—The book of Revelation was written during a time of fierce persecution. The clash between the Roman Empire and the Christian Church had already commenced. The establishment of Emperor worship as the national religion of the Empire was a challenge to Christianity. It was impossible for devoted Christians to take part in the rites and ceremonies which Emperor-worship entailed. Their refusal led to a charge of disloyalty, and brought them into bad odour with the populace. Only one martyr is mentioned by name in the book itself (Antipas ii. 13), but there is a reference in vi. 9 to 'the souls of them that had been slain for the word of God and for the testimony which they held'—which shows that martyrdoms must have been common at the time. According to the statement in xiii. 15, an edict was issued that as many as would not worship the image of the beast (i.e. the Emperor) should be killed. Moreover, the profession of Christianity entailed social ostracism and a commercial boycott. The devotees of the cult of Caesar wore on their right hands or foreheads a special sign, and all who did not bear the 'mark of the beast,' as it was called, were not allowed to buy or sell in the markets. The very existence of Christianity was at stake. And, just as the book of Daniel was written to encourage the Jewish people to remain loyal to God under the fiery persecution of Antiochus Epiphanes, so the book of Revelation was composed to comfort Christians in the distress caused by the effort of Domitian to destroy the Christian faith.

Methods of Interpretation.—The book of Revelation has always been a riddle and enigma to Christian thinkers. Even before the days of Dionysius of Alexandria there were critics who attempted to refute the book as a whole, criticising every chapter and pronouncing it unintelligible and nonsensical. Many attempts have been made to find the key for the interpretation of the book. (1) One theory generally known as 'the continuous historical' maintains that the book contains a complete chart of human history from the writer's own day to the end of the world. Part of it therefore belongs to the past and part of it is still to be realised in the future. This explanation, however, is generally discredited to-day. The writer says specifically that his statements 'must shortly come to pass.' He expects that his prophecies will be realised in his own age. Moreover, it is impossible to identify the forecasts of the Apocalypse with anything that has happened in human history during the 1900 years which have elapsed between the

writer's day and ours. (2) The second theory, which is generally called 'the futurist,' holds that the prophetic elements in the book of Revelation refer to the events which will happen in connection with the end of the world. They are not concerned at all with the intermediate history, but deal only with the drama which is to be enacted at the final *dénouement*. This theory is open to the same objections as the first. It is in conflict with the writer's explicit statements with regard to the proximity of the events recorded, and it is false to the whole spirit of prophecy. (3) A third theory, which is associated with the name of Dr Milligan, rejects the two preceding views as impossible and absurd, and maintains that the book of Revelation deals with the eternal warfare between the principles of good and evil in the history of the Church. The details must not be pressed—they are merely the poetic imagery in which the theme is worked out. 'The Apocalypse resembles all true prophecy which, whether in the Old Testament or the New, contains mainly the enunciation of great principles of God's government of men and not the prediction of special events. Even when the latter are predicted it is generally less for their own sake than for the principles they illustrate' (*Lectures on the Apocalypse*, p. 154). 'Thus, then, we are not to look in the Apocalypse for special events, but for an exhibition of principles which govern the history both of the world and of the Church.' Milligan's theory fails to meet the real needs of the case. It imposes an interpretation upon the book rather than elicits one from it. It evades the real difficulties and ignores the real problems. It was propounded at a time when Apocalyptic was a *terra incognita* and the real key to the meaning of the book had not yet been discovered. (4) The theory which is generally accepted by modern scholars is called 'the preterist.' It insists that the book of Revelation can only be interpreted in the light of the circumstances under which it was first written. It is relevant only to the situation which existed in the 1st century. Its predictions can only be explained in the terms of the history of the 1st century. The writer calls to his aid the ideas of Apocalyptic in order to meet the needs of his own age. He looked for the fulfilment of his prophecies within the limits of his own generation. He expected in his own day a great act of Divine intervention to vindicate the saints and inflict punishment upon their persecutors. His predictions were never fulfilled in the sense in which they were uttered. The end did not come as he anticipated; but in a different and a greater way God did protect his people and enable them slowly but surely to conquer the world.

The Question of Authorship.—The only indication which the book itself offers with regard to its author is found in the opening verse, where the writer's name is said to be John, and he is described as one 'who bore witness to the word of God' (i. 2), 'a brother and partaker in the tribulation of the saints' (i. 9), an exile in the isle of Patmos, 'for the word of God and the testimony of Jesus.' These statements do not in themselves offer us any sure ground for identifying him with the Apostle John, but later Christian tradition assumed this identification as a fact. Justin Martyr is the first to make a categorical assertion on the subject. 'A certain man,' he writes, 'whose name was John, one of the apostles of Christ, prophesied in a revelation made to him that the believers in our Christ should spend a thousand years in Jerusalem.' This opinion was not challenged till the 3d century, when Gains of Rome (210) and Dionysius of Alexandria denied on grounds of style and subject-matter that the fourth gospel and the book of Revelation could be the work of the same author.

Recent modern criticism corroborates the protest of Dionysius on the following grounds: (a) Ancient testimony is by no means unanimous as to the Johannine authorship. In many quarters the book was rejected from the New Testament canon, and this could not have been the case if its apostolic authorship had been universally accepted. (b) In subject-matter the character of the two books is widely different. In the fourth gospel the Apocalyptic element is at a minimum—in the Apocalypse it dominates every page of the book. (c) In style and phraseology there is the utmost diversity between the two documents. No man could possibly have written them both unless in the interval his style—and not only his style, but the personality of which that style was the expression—had been completely revolutionised. In fact, every unbiased critic is compelled to admit that from almost every point of view the two books stand at opposite poles of thought. Some modern scholars have connected the authorship of the book with John the Presbyter, but the evidence is far too slender to warrant the deduction which is based upon it. Nor is it a likely theory to suppose that the author pseudonymously attempts to father his work on either John the Apostle or John the Presbyter. If that had been the case his description of the assumed author in the first chapter would have been much more definite and precise than it actually is.

The Sources of the Book.—Modern criticism has attacked the unity of the book and tried to prove that as it stands it is a compilation from many different sources. The first suggestion was made by Evanson as far back as 1792. Fastening on the differences which mark off the first three chapters from the rest of the Apocalypse, Evanson maintained that the letters to the seven churches, together with the introductory paragraphs of chap. 1, did not properly belong to the book at all, but were a later insertion. Vogel, in 1811-16, made the interesting suggestion that the Apocalypse was the work of two different authors—one of whom was John the Apostle, and the other John the Presbyter. His theory was worked out more fully in 1820 by Bleek, who thought the actual author of the book was John the Presbyter, who combined together two different works—the one containing chap. iv. 11, written before the fall of Jerusalem, the other containing chap. xii.-xvii., and written after A.D. 70, foretelling the doom of Rome. The theory of a composite origin for the book received a new and important stimulus by the publication of Volter's elaborate theory in 1882. The composition of the Apocalypse passed through five stages: (a) The original groundwork was written by the apostle himself in 63. (b) To this ground he subsequently made additions. (c) Other additions were made in the reign of Trajan. (d) Others, again, in the reign of Hadrian. (e) The final redaction did not appear till the time of Antoninus Pius. A new turn was given to the discussion in 1888 by Vischer, who maintained that the groundwork containing the bulk of the Apocalypse was of Jewish origin, and that this was subsequently expanded by a Christian writer who added the opening and closing chapters and made a few insertions in the general body of the book. Vischer's theory caused a great stir when it was first produced, and won the adhesion of Harnack, who said that it made him feel 'as if scales had fallen from his eyes.' But the theory has failed to secure general support, because it is felt that the Christian elements are so woven into the tissue of the book that they cannot be so lightly detached as Vischer imagined. The compilation hypothesis has been further developed in recent times by Weyland (1886), Ménégos (1888), Kohler and Eugène de Faye (1892), much of which is based

upon Spitta's important work (1889). Most of these theories assume as their basis two Jewish Apocalypses, and maintain that these have been woven together by a later Christian redactor who also inserted much new material of his own. Other modern scholars—e.g. Weizsäcker, Sabatier, Bousset, Schen, and McGiffert, while regarding the compilation hypothesis as too complicated to admit of demonstration, think that there is clear evidence that the writer of the Apocalypse incorporated a large amount of old material into his work. There is no general agreement as to the details, but all these scholars think that there is sufficient evidence to prove that the bulk of chap. xi. and xii. is derived from older sources—and it is probable that similar material is inserted in chap. vii., viii., xiii., xviii., and xix. Dr Charles, in his investigations (*Studies in the Apocalypse*, 1913, and in his *Commentary*, 1920), thinks that it is possible to find traces of the combination of two Apocalypses in chap. viii., and he holds, too, that chap. xx.-xxii. have been disarranged in process of transmission. Gunkel's great book *Schöpfung und Chaos* (1895) made a contribution of a different kind to the interpretation of the Apocalypse. He is far more interested in the origin of the ideas of the book than in its literary analysis, and thinks it is only through the study of comparative mythology that the key for understanding the Apocalypse will be found. The best account of the modern theories is to be found in Moffatt's *Introduction to the Literature of the New Testament*, pp. 489-496.

The Date of the Book.—Ancient tradition assigns the book to the reign of Domitian (81-96). Irenaeus, for instance, says 'the vision of the Apocalypse was seen not a long time ago, but almost in our own generation, at the end of the reign of Domitian.' The statement of Irenaeus is endorsed by Eusebius and Jerome; and, though it is not unanimously accepted (since Epiphanius dates the banishment of John in the reign of Claudius, and the Syriac versions in the reign of Nero), it represents the predominant opinion of the early church. Some attempts, however, have been made in modern times to set aside this tradition and give an earlier date to the book. Both conservative and advanced critics have for different reasons combined to put back the date of the book. The conservatives were anxious to make the interval between the composition of the Apocalypse and the fourth gospel as long as possible, because they claimed John as the author of both books, and were compelled to find time for the development of his ideas and his linguistic style. Radical critics, on the other hand, like Barr and the Tübingen school, felt that an early date fitted into their scheme much better than a later. The internal evidence upon which those scholars who attribute the book to the reign of Nero mainly rely is the statement in xi. 1, which implies that the temple at Jerusalem is still standing. Those scholars, on the other hand, who prefer a date in the reign of Vespasian rely upon the reference to the seven kings in xvii. 11, and urge that this statement implies that the reigning emperor at that time was Vespasian; and, moreover, the frequent allusions in the book to *Nero redivivus* make it quite certain that Nero himself could not have been alive at the time when the book was published in its present form. There are, however, several fatal objections to a date earlier than the time of Domitian. (1) There is no evidence that the cult of Caesar worship attained the dimensions implied by the book of Revelation before the time of Domitian. As Moffatt says, 'No worship of the Emperor which is adequate to the data of the Apocalypse was enforced till Domitian's reign.' (2) There is no evidence that there was before the time of Do-

mitian any such persecution in Asia as is described in the Apocalypse. The Neronic persecution was limited almost entirely to Rome, and, though there may have been spasmodic outbreaks in Asia between Nero and Domitian, there is no proof that they were as serious as the book of Revelation implies. (3) The allusion to the 'eighth emperor' in xvii. 11 carries us beyond the time of Domitian—at least upon what seems to be the most reasonable interpretation of the passage. There seem to be no adequate grounds, therefore, for disputing the Domitianic date. The indications which seem to point to an earlier period are probably best explained by supposing that they represent earlier material which the writer incorporated into his book.

The Value of the Book.—The Apocalypse seems at first sight to be the book of least spiritual value in the New Testament, especially now that modern criticism has robbed it of its prophetic interest. It is not easy to adjust the mind to the new perspective, but at any rate certain things appear to be visible through the mist. (1) The book is a record of the triumph of faith. Christianity has never had to face a more desperate situation than in the reign of Domitian. It was threatened with annihilation, and it seemed useless to struggle against the antagonism of the Empire. And yet it was in those dark and perilous days that the faith of the church shone out most brightly. It was possessed with the invincible conviction that God would intervene in order to save his chosen people. It pictured in its own way the form which the intervention would take. As far as the form was concerned, its faith was doomed to be disillusioned. But in other ways—ways surpassing what was possible to the imagination of its people at the time—God did vindicate his righteousness and save his church from disaster. As a story of one of the greatest achievements of faith known to history, the book of Revelation is of incomparable value. (2) In its conception of Christ it has made a useful contribution not only to faith but to Christology. Bousset has asserted that 'the Christology of the Apocalypse is the most advanced in the New Testament.' This perhaps may be an exaggeration, but it can scarcely be denied that no more exalted conception of Christ is to be found than in its pages. Much of its Christological interpretation is couched in Jewish Messianic categories, and sometimes, as in chap. xi., mythological ideas are pressed into service, and yet no description of Christ in the pages of the New Testament exceeds in poetic beauty and richness of thought the portrayal which we find in i. 12-18. (3) The letters to the Seven Churches will always have their appeal to the Church of Christ, because they deal with conditions and difficulties which for the most part are not confined to the 1st century but are common to all the ages. (4) The book does bear a remarkable witness to what must always be an essential element in the Christian faith—the belief in the ultimate victory of Christ.

The best edition of the Greek text of the Apocalypse is that of B. Weiss (with critical notes), 1891. The best modern commentaries are those of Bousset (2d ed. 1906), Holzmann-Bauer (1908), Spitta (1889), Swete (1906), Benson (1900), C. A. Scott ('Century Bible'), Moffatt ('Expositor's Greek Testament'), A. Ramsay ('Westminster New Testament'), Charles ('International Critical Commentary', 1920). The following books deal with problems of criticism and interpretation. Peake, *The Revelation of John* (1919); Bleek, *Lectures on the Apocalypse* (1875); R. H. Charles, *Studies in the Apocalypse* (1913); W. M. Ramsay, *The Letters to the Seven Churches* (1904); Milligan, *Lectures on the Apocalypse* (1892), *Discussions on the Apocalypse* (1893); C. H. Turner, *Studies in Early Church History*, pp. 189 ff. (1912); Burkitt, *Jewish and Christian Apocalypses*.

Revels, MASTER OF THE, an officer attached from an early date to the English royal court, whose function it was (distinct from the Lord of Misrule; see FOOLS, FEAST OF) to preside over the amusements of the court, especially during the Christmas holidays. A functionary of the kind seems to have been required in the days of Edward III.; under Henry VII. he was a recognised officer. He became a permanent appendage to the English court in the reign of Henry VIII., and his duties included the keeping of the tents and pavilions which accompanied the sovereign on a royal progress, as also the keeping of the dresses and masks used in entertainments given at court, and the providing of new ones when required. In Queen Elizabeth's time the Mastership of the Revels extended his authority to a general supervision of the stage, and his office was absorbed in that of the lord chamberlain early in the 17th century. See various works by Sir E. K. Chambers and by Mrs C. C. Stopes.

Revenue. The inland revenue is distinguished from the Customs Duties (q.v.), and includes (1) the Excise (q.v.), comprising alcohol duty, liquor and luxury licenses; (2) Stamps, with the 'death duties'—probate, account, legacy, and succession duty; (3) Taxes—property and income tax, &c. (see TAXES). The right of the Commons to regulate taxation and the outlay of the national income is treated at PARLIAMENT.

Reverberatory Furnace, a furnace so constructed that ores and other materials may be heated in it without coming in direct contact with the fuel. It consists essentially of three parts—viz. a fireplace at one end; in the middle a flat bed or sole, on which the material to be heated is placed; and at the other end a chimney to create a draught and to carry off the smoke or fume. Between the fireplace and the bed a fire-bridge is placed, and the whole built over with a flat arch, dipping towards the chimney. The flame plays over the fire-bridge, and the heat is reflected, or *reverberated*, on the material beneath; hence the name. See COPPER, LEAD, and IRON (puddling furnace).

Revere, PAUL, famous for his midnight ride, was born in Boston, Massachusetts, 1st January 1735, the son of a goldsmith from Gnermsy, whose trade he followed after serving as a lieutenant of artillery in the expedition against Crown Point (1756). He also engaged in copperplate printing, and before the Revolution constructed a gunpowder-mill. A keen patriot, he was one of the party that destroyed the tea in Boston harbour, and he was at the head of a volunteer committee, consisting of thirty young mechanics, who formed a secret society to watch the British. When it was known that the latter intended to move, Revere crossed over to Charlestown, and on April 18, 1775, the night before Lexington and Concord, at a signal rode on to Lexington and to Lincoln, rousing the minute-men as he went; at Lincoln he was stopped, but a companion succeeded in reaching Concord. During the war he rose to lieutenant-colonel of artillery; afterwards he returned to his goldsmith's work, and in 1801 founded the Revere Copper Company at Canton, Massachusetts. He died 10th May 1818. His ride is the subject of a well-known poem by Longfellow.

Reverend (Lat. *reverendus*, to be respected), a title of respect given to the clergy. In the

Anglican Church deans are 'Very Reverend'; bishops, 'Right Reverend'; and archbishops, 'Most Reverend.' In Scotland the clergy in general are 'Reverend', while it is now customary to use 'Right Reverend' of the moderator of the General Assembly, and 'Very Reverend' of ex-moderators and principals of universities, being clergymen. The style 'Reverend' is generally adopted by and given to the clergy of the different dissenting bodies; and in 1876 the Privy-council decided on appeal that there is no law restricting it to ministers of the Church of England. There have, however, been instances in which some dissenting ministers have repudiated it. See ADDRESS (FORMS OF).

Reversion is the right to the enjoyment of money, or of any kind of property, postponed until or contingent on the happening of a given event. Reversions are usually divided into three classes: Absolute Reversion, in which the emergence of the rights is certain, Contingent Reversion, and Reversionary Life Interests. In the first case, when the date of the emergence is also fixed, the value of the reversion is dependent merely upon the operations of interest (see INTEREST). When the date of the emergence of the reversionary right is uncertain, the purchase in an individual case must always be a speculation; but if there are a sufficient number of such rights, postponed to events of which there are sufficient observations from which to deduce laws of average, then the marketable value is easily calculated. For example, it is required to know what is the immediate value of £100 payable certainly on the death of a man aged sixty. Here the value of the reversion is £100, under deduction of the prior life interest, which in this case is the present value of an annuity equal to the interest of £100 on the life of a male aged sixty. When an insurance company buys a reversion, it is simply buying that which it sells when it grants a policy of life assurance. In the former case, however, an office, to secure its expenses and profits, will assume a high rate of interest and a long life; in the latter case, for the same reason, it will assume a low rate and a short life. By the Sale of Reversions Act, 1867, no purchase of a reversion is challengeable on the ground of undervalue merely. Where the reversion is contingent, problems arise whose solution requires the utmost skill on the part of the actuary. For instance, B, aged thirty, wishes to borrow £100 on the security of a sum payable to him in the event of his surviving A, aged fifty-eight. Here the security being doubtful, it could only be rendered marketable by assuming a sum to be paid in the event of B dying before A; and there would remain the important question of what this sum should be, so as to cover the loan and the premiums of assurance with yearly accumulations on both. The value of a reversionary life interest is found by deducting the value of a joint life annuity from the value of the annuity on the life of the survivor (see the Institute of Actuaries' text-book, part ii.).

In law a reversion is that right to property which remains after some particular estate has ceased which had been granted by the owner. Thus, before 1926, if A had a life-estate in B's property, and after he died the property returned to B, B was said to have the reversion or to be the reversioner. But by the passing of the Law of Property Act, 1925, after 1926 the only legal reversions are: (1) The estate of a tenant in fee simple where the land has been granted to another for a term of years; and (2) The estate of a tenant for a term of years who has granted a smaller term of years to a sub-tenant. Thus, if A is tenant in fee simple of land and grants it to B for 99 years, A has a freehold reversion. In Scots law reversion means the

right of redemption retained by a borrower over an estate disposed in security.

Reversion, a term applied when organisms exhibit ancestral traits which their parents do not possess, e.g. a fourth toe on a guinea-pig's hind-foot, or cross stripes on the fore-quarters of a horse. But many phenomena which have been called reversions admit of other interpretations. See ATAVISM, HEREDITY.

Revilla-Gigedo, a rocky and uninhabited island group in the Pacific, 400 miles west of the coast of Mexico, to which it belongs. The largest of the islands is 20 miles long.

Révile, ALBERT (1826 1906), a French Protestant theologian, was born at Dieppe, studied at Geneva and Strasburg, and was pastor of the Walloon Church at Rotterdam in 1851-72. Then he lived near Dieppe until his call in 1880 to the chair of the History of Religions in the Collège de France.

Revising Barrister. See BARRISTER.

Revival, or REVIVAL OF RELIGION, a term employed to denote an increase of faith and piety in individual Christians, particularly after a period of religious declension, and also an increase of religion in a community or neighbourhood, both through the revival of those who are already religious, and through the conversion of the previously irreligious. Such religious movements frequently extend, more or less generally, over a neighbourhood, or sometimes over a country. Instances of a similar kind are recorded in the Scriptures as occurring both in the history of the Jews and in the early history of the Christian church, particularly in the effusion of the Holy Spirit on the day of Pentecost, and afterwards in connection with the ministry of the apostles, when many were converted through a single discourse, or, in other cases, evidently within a short time. In the middle ages revivals took place in connection with the Crusades and under the auspices of the monastic orders (see CHURCH HISTORY); and sometimes with repulsive adjuncts, as in the case of the Flagellants (q.v.) and the Dancing Mania (q.v.). The Reformation of the 16th century, and the more partial movements of the same kind which preceded it, are also regarded as essentially revivals of religion—the Reformation itself the greatest which has taken place since the apostolic age. In Scotland there were notable 'works' in 1625 at Irvine and Stewarston, in 1630 at Kirk-of-Shotts, and in 1638. After the Reformation the next wide-spread movement of the kind was that in the first half of the 18th century from which the Methodist churches originated. It was accompanied with many circumstances similar to those which have attended later revivals of religion. The term revival did not begin to be commonly employed till after this period; and the revival which took place in New England and other parts of North America about the same time under Edwards, Bellamy, and the 'enments was generally designated the Great Awakening. The beginning of this revival seems to have had no connection with the Methodist movement in England, although subsequently they became connected through Whitefield's visits to North America. There were revivals at Cambuslang in 1742, and at Monin in Perthshire in 1798-1800. A very extensive revival in Wales resulted in the formation of the Welsh Calvinistic Methodist Church, but was not confined in its effects to those who became connected with that church. Local revivals also in some instances attended the ministry of evangelical ministers of the Church of England; and in America there were revivals in 1796, in

1812-15, and again in 1827-32. In 1839 the attention of all Scotland was drawn to a religious movement at Kilsyth, originating in the preaching of William C. Burns (q.v.), and this was followed by similar occurrences in a number of other places, more or less evidently connected with it. The great American revival of 1859-61 began in New England, particularly in Connecticut and Massachusetts, and rapidly extended to New York and over the middle and western states. It was not generally attended with scenes of great excitement; strong but calm religious feeling was its general characteristic. It spread all over the United States, and it was believed that in a single year half a million converts were received into the churches. A similar movement took place in Ireland, and rapidly extended over the whole north, and subsequently to Scotland, Wales, and some parts of England, characterised less by excitement than intensity of religious feeling. Another remarkable revival originated about 1873 in the labours of two American evangelists, Moody (q.v.) and Sankey, and, like the Welsh revival under Evan Roberts in the winter of 1904-5, evoked little sensationalism. From America again came Torrey, Alexander, and Chapman. The Camp-meetings (q.v.) have been a great feature of American Methodism. The Salvation Army carries on its work largely by methods known as revivalistic. Revivals of religion have occurred also in other parts of the world. Sometimes they come as the reaction from national disasters, or in times of national crises, or are associated with natural phenomena, earthquakes, comets, eclipses, and so forth. Conversion (q.v.) is more likely to take place in the case of people of nervous or sensitive temperaments. Scientific diagnoses such as epileptic fits, states of catalepsy, have been put forward in explanation of the 'shafts of light,' 'crosses in the sky,' and other luminous manifestations some times reported at the moment of conversion.

See Fleming, *Fulfilling of the Scripture* (1681); Edwards, *The Work of God in Northampton, Massachusetts* (1736); Pringle, *Surprising Accounts of the Revival of Religion in the United States* (1802); Finney, *Lectures on Revivals of Religion* (1835, new ed. 1924); Traey, *The Great Awakening* (1842); Bushnell (who depreciates the value of revivals), *Christian Nurture* (1847); Gibson (writing about Ireland), *Year of Grace* (1860); Fish, *Handbook of Revivals* (1874); Overton, *Evangelical Revival of the 18th Century* (1886); James, *Varieties of Religious Experience* (1902); Henri Bois, *Le Réveil au Pays de Galles* (1906). See also METHODISM, and the books there cited; and the journals and biographies of the Wesleys, Whitefield, the Haldanes, Barnes, Moody, Torrey, Chapman, and other eminent evangelists.

Revival of Learning. See RENAISSANCE.

Revolution, any extensive change in the constitution of a country suddenly brought about. The most important events in modern history specifically known under this name are the English revolution of 1689 (Guizot by 'Revolution' means the 'Great Rebellion'); the American revolution of 1776; the French revolution of 1789; the revolution of 1830 ('the July revolution'), which deposed Charles X. and raised Louis Philippe to power; the revolution of 1848 ('the revolution of February'), which established the second republic; and the revolutions by which the South American republics were established or are from time to time modified. The revolutionary periods are *par excellence* the years 1848-49, and the end of the Great European War. The French change of constitution in 1871 is not usually spoken of as a revolution, though in effect it was one. For the Revolutionary Tribunal, see DANTON.

Revolver. Revolving firearms date from the

beginning of the 17th century, when hand-guns having two or more barrels were mounted to turn upon an axis, and so arranged that the powder-pans came successively under the action of the lock; the barrels were not rotated by pulling the trigger, but were turned by the hand. The celebrated Marquis of Worcester invented several such. In 1815 Le Normain, a Parisian gunsmith, produced a pistol with five barrels, Devisme one with seven, but neither proved successful. The 'Marianne,' made with from four to twenty-four barrels, was the first to become popular, although from its weight, cumbersome mechanism, and short range, it could have been of little use except at close quarters. This pistol was the precursor of the 'pepper-box' pistol, to which it was closely allied; the barrels of both were bored in a solid mass of metal, and made to revolve as the hammer was raised to full cock. Not so old as the principle of revolving barrels, but still an invention of past generations, is that of a revolving chamber or breech-piece, pierced with cylindrical apertures to contain the charges, and so arranged that each chamber came successively into line with the barrel and lock common to all. E. H. Collier in 1818 patented an improved carbine with three revolving chambers, which appears to have been an efficient weapon. Colonel Samuel Colt produced his world-renowned revolver in 1835. This consists of a rifle barrel, a revolving cylinder with six or seven chambers, each furnished with its own nipple and cap, and a lever trigger, which operates the mechanism required to turn the chambers and fire the weapon. The double-action revolver is one in which by simply pulling the trigger the hammer is raised and released, and the chambers turned; whilst in the single-action revolver the hammer is raised by the thumb of the firer and released by the trigger. Breech-loading revolvers are of two kinds—the solid frame revolver, which requires the empty cases to be forced out by a diminutive ramrod (generally attached to the pistol by a swivel), and the self-extracting revolver, of which there are many kinds.

Revue des Deux Mondes, the best known of the French magazines devoted to literature, art, and general criticism, was founded in Paris in 1831 by François Baloz. It had appeared during 1829, but was languishing until purchased by Baloz, who firmly established it. Many of the best French writers have contributed to its pages.

Rewa, a state of India, in the Baghelkhand Agency.—**REWA KANTHA** is the name of a political agency under the government of Bombay, containing sixty-two small states, of which four are tributary to the British government, and most of the remainder to Baroda. The territory included, covering an area of 5000 miles, with a total population of 753,000, lies mainly along the south bank of the lower Nerbudda with patches north of it, and on the west borders on Broach, Baroda, and Ahmedabad.

Reward, in a legal sense, means some encouragement which the law holds out for exertions in bringing certain classes of criminals to justice. By statute 7 Geo. IV. chap. 64, the courts of assize may order the sheriff of the county in which certain offences have been committed to pay to persons who have been active in securing the apprehension of offenders charged with murder, or with feloniously shooting, cutting, stabbing, wounding, or poisoning, or with rape, burglary, housebreaking, robbery, arson, or cattle-stealing, or with being accessory before the fact to any of such offences, or to receiving any stolen property, a reasonable sum to compensate them for expense, exertion, and loss of time. So by a later statute—

(14 and 15 Vict. chap. 55) courts of quarter sessions are authorised, in the case of any of the above offences which they have jurisdiction to try, to order such compensation; but the payment to one person must not exceed £5. If any one is killed in endeavouring to apprehend a person charged with one of these offences, the court may order compensation to be made to the family. The High Court has also a general power to order the payment of a reasonable sum to any person who has shown unusual courage or diligence in apprehending offenders. By the Larceny Act, 1916 (6 and 7 Geo. V. chap. 50), sec. 34, it is a felony, punishable by penal servitude to the extent of seven years, to corruptly take any reward for helping a person to recover property stolen or embezzled, unless all due diligence to bring the offenders to trial has been used. By the Larceny Act, 1861 (24 and 25 Vict., chap. 96), sec. 102, an advertisement offering a reward for the return of stolen or lost property, using words purporting that no questions will be asked or inquiry made after the person producing the property, renders the advertiser, printer, and publisher liable to forfeit £50 to any person who sues for the same. An action to recover the forfeiture from the printer or publisher of a newspaper can only be brought within six months after the forfeiture is incurred and requires the written assent of the Attorney-General or Solicitor-General.

When a reward is advertised for the recovery of lost property, or for information, or for doing any other act, the performance of the act constitutes an acceptance of the offer in the advertisement, and the person performing the act is entitled to sue for the reward.

Rewari, a town of the district of Gurgaon, in the extreme south of the Punjab, 50 miles SW. of Delhi by rail, an important centre for trade between Punjab and Rajasthan; pop. 23,000.

Reykjavík, the capital of Iceland, is situated on the south coast of Faxa Bay, in the west of the island. The first Norse settlers are supposed to have made their home there in the 9th century, when Ingólfr Arnarson after three years' search found on the beach the high seat pillars he had thrown overboard; but till near the end of the 18th it remained a small fishing village. Some factories were set up and a trading-station established, but growth has been slow. A good sheltered harbour constructed since 1913. The most noteworthy buildings are the Alþingishúsi or Parliament House, the Cathedral (the seat of the Bishop of Iceland), the National Museum (containing also the large National Library), and the University (with four faculties). The Hnitbjörg museum contains a collection of Einar Jónsson's sculptures. Reykjavík also possesses banks, hospitals, and various schools, and exports a considerable amount of fish, chiefly cod, herring, and salmon, mostly salted. Pop. (1850) 1000; (1901) 6600; (1920) 17,679.

Reymont, WŁADYSŁAW STANISŁAW (1868-1925), Polish novelist, the son of a peasant, was for some time a strolling player and a railway worker, before definitely taking to literary work. He won the Nobel prize in 1924 for his huge novel, *The Peasants* (1904), a description of life on the land during the four seasons. His other chief work is *The Promised Land*, written after a stay in the industrial town of Łódź. Reymont is a realist, with an acute sense of observation and a keen sympathy with humanity.

Reynard the Fox, a well-known popular epic the characters of which are animals instead of men. It belongs to the series of Beast-fables (q.v.) which have delighted the popular imagination from early ages and in all lands, from India

to the Bushmen's country in South Africa (see FABLE). The stories that relate the knaveries of Reynard the Fox seem to have originated for the most part in northern France and Flanders from the 10th century onwards, and to have been composed and recomposed repeatedly in various forms in the 12th and following centuries. The authors or editors, so far as they are known, belonged chiefly to the ecclesiastical orders. The several versions differ not only in respect of language and of style, but also in the choice and arrangement of the episodes and incidents narrated. All turn upon the knaveries of Reynard the Fox, as practised by him in his quarrel with Isengrim the Wolf, who in all encounters generally comes off second best. The best versions, as the typical Flemish and Low German (to be referred to in detail lower down), reach a high level of literary excellence. The episodes are woven together into a veritable epic; the versification is agreeable and easy; the characters are consistent and well-sustained; the contemporary manners, and the localities and circumstances, that make the background of the story are true and realistic; and the story is told without any other obvious purpose beyond that of affording honest amusement. These features do not, however, characterise all the versions: some have been clearly written for a satirical purpose, some are loosely-connected strings of ill-told adventures, others drag out a long and weary length through innumerable indifferent verses, whilst in others still the characters are simply men disguised as animals. The earliest versions were in Latin; but they seem to have been soon supplanted by French in the 12th century, and in their new dress the stories attained a much wider popularity. Since the beginning of the 16th century nearly all the editions printed can be traced back to one of two sources, a Flemish or a Low German, both of which, however, are based upon French forms of the epic. The task of tracing the connections between the numerous versions that exist in the different tongues is one of great complexity and difficulty. It will suffice in this place to enumerate the more important, with mention of one or more trustworthy recent editions. The best Latin version, *Isengrimus* (ed. by Mone as *Reinardus Vulpes*, Stuttgart, 1832; and by Voigt, Halle, 1884), which possesses considerable literary merit, was written in Flanders about 1146-48 by an unknown author. The *Isengrimus* printed in J. Grimm's *Reinhart Fuchs* (Berlin, 1834) is not an older, but a later and abbreviated, form of the same poem. The best French versions that survive were edited by Méon (4 vols. Paris, 1826), with a supplement by Chabaille (1835), and by Martin (4 vols. Strasbourg, 1882-88). They were written between the middle of the 13th and the middle of the 14th century, and run to enormous length, the separate cycles or groupings of the episodes being called 'branches'. Méon's work includes three cycles: (1) *Roman de Renart*, apparently the work of three if not more authors, Pierre de St Cloud, a priest of Lacroix in Brie, and a Norman priest Robert de Lison; (2) *Le Couronnement de Renart*, attributed to Marie le France; and (3) *Renart le Nouvel*, by Jacquemars Gielee of Lille, about 1290. The last two are transparent satires upon certain of the monastic orders. There is a fourth cycle, a voluminous compilation or imitation by a priest of the neighbourhood of Troyes, made near the middle of the 14th century, and entitled *Le Renart Contrefait* (ed. F. Wolf, Vienna, 1861). The oldest extant High German version, *Reinhart Vuchs* or *Fuchs* (ed. Roissenberger, Halle, 1886), more usually called *Reineke Fuchs*, was adapted by some one unknown, early in the 13th century, from a still older version, *Isengrimus Nöt*, itself a trans-

lation made from old French sources about 1180 by an Alsatian, Heinrich der Glieschære. The Flemish version which has been the basis of most of the translations, continuations, and editions that have been made since the invention of printing is entitled *Reynart de Vos* (ed. Martin, Paderborn, 1874). It was written by one William, but whether William de Mator, William Utenhove, or more probably an unknown William, is uncertain, and dates apparently from the middle of the 13th century. The source upon which it is built is the nineteenth 'branch' in the *Roman de Renart* (last in vol. i. of Méon). The text that has been almost exclusively used in the later translations, &c., is that of a second edition, deviating in some respects from William's own, notably in the infusion of a didactic, satirical tendency; the author of this second edition is not known. It was from a prose version of this second edition, published at Gonda in 1479, that Caxton made his translation of *The History of Reynard the Fox* (1481; reprinted Edin. 1884). Upon this same edition was based the Low German version, *Reinke de Vos* (ed. Prien, Halle, 1887), which has been more often translated perhaps than any other version. Who the Low German translator was is not known, in spite of the question having greatly exercised many specialists. The *editio princeps* of *Reinke* is that of Lubeck (1498), and next to it stands that of Rostock (1517). There are Danish (by A. H. Weigere, Lubeck, 1555), Swedish (Stockholm, 1621), and several other High and Low German editions, for which, however, see the bibliography prefixed to Prien's *Reinke*. Nevertheless special mention must be made of Gottschel's High German prose version (1752) and Goethe's well-known High German poem, with Kaulbach's scarcely less known illustrations to the same. Popular High German translations are contained in Simrock's *Deutsche Volksbücher* (vol. i. 1845) and Mabaeh's *Volksbücher* (vols. xv.-xvii.).

English readers should consult the introduction to W. J. Thomas's edition of Caxton's *Reynard* (1845), Carlyle's *Miscellaneous Essays* (not quite accurate), F. S. Ellis's *History of Reynard the Fox* (1894), Joseph Jacobs's introduction to his version (1895); *The Epic of the Beast consisting of English translations of Reynard the Fox and Physiologus* (introd. by William Rose, 1924).

Reynolds. JOHN FULTON, an American general, was born in Lancaster, Pennsylvania, 20th September 1820, graduated at West Point in 1841, and became commandant there in 1859. As brigadier-general he fought at Mechanicsville and Gaines's Mills, and was taken prisoner at Glendale, but exchanged in August 1862. At the second battle of Bull Run his own bravery induced his brigade to stand fast, and so prevented a complete rout. In November he was commissioned major-general, and in 1863 commanded a corps at Fredericksburg. He was killed at Gettysburg, where he commanded the left wing, on 1st July 1863. The state erected a granite shaft on the spot where he fell, and his men a bronze heroic statue on the field; and in 1884 an equestrian statue was unveiled in Philadelphia.

Reynolds. Sir JOSHUA, P.R.A., portrait and subject painter, was born at Plympton Earls, near Plympton, on 16th July 1723, the year of Kneller's death. His father, a clergyman and master of Plympton grammar-school, intended him for the medical profession; but he developed a strong aptitude for painting, was continually studying the plates in Cats's *Book of Emblems*, Dryden's *Plutarch*, and the other volumes that came in his way, and at the age of eight had mastered the *Jesuit's Perspective*, and applied its principles to drawings executed by himself. In October 1740, accordingly, he was sent to London to study art,

and placed in the studio of Thomas Hudson, a portrait-painter, of very moderate abilities, much employed at the time. In 1743 he returned to Devonshire, and some of the portraits of local worthies which he then produced still exist. In the following year he was again in London pursuing his art; but in the beginning of 1747, after the death of his father, he settled in Plymouth Dock, now Devonport, where he learned much from a study of the works of William Gaudy of Exeter. In 1749 he made the acquaintance of Commodore, afterwards Lord, Keppel, who invited him to accompany him on a cruise in the Mediterranean; and, after painting many of the British officers in Minorca, he made his way to Rome, where he studied Raphael and Michelangelo, and in the Vatican caught a chill which permanently affected his hearing, and necessitated his use of an ear-trumpet during the rest of his life. He also visited Bologna, Genoa, Florence, Parma, and Venice. Returning to England in October 1752, he soon afterwards established himself in a studio in St Martin's Lane, London, and attracted notice by his portraits of the second Duke of Devonshire and Commodore Keppel. Before long he was in excellent practice, and in the year 1755 he had no fewer than a hundred and twenty sitters, of whom he produced portraits in which the influence of the Italian masters, and especially of Correggio, is clearly visible; works in which he was certainly aided by such assistants as Murelli, but which he impressed with his own character and individuality. He soon removed to Great Newport Street; and finally, in 1760, he purchased a mansion on the west side of Leicester Square, to which he added a studio and reception-room.

He was now at the height of his fame, and a valued friend of his most celebrated contemporaries. In 1764 he founded the famous literary club of which Dr Johnson, Garrick, Burke, Goldsmith, Boswell, and Sheridan were members; all of whom were portrayed by his brush. He was one of the earliest members of the Incorporated Society of Artists, and contributed to its exhibitions till 1768, when, on the establishment of the Royal Academy, he was elected its first president; and in the following year he received the honour of knighthood from the king. In 1769 he delivered the first of his Discourses to the students of the Academy, fifteen of which have been published. They are full of valuable and well considered instruction, and, along with his papers on art in the *Illustrator*, his annotations to Dr Friesnoy's *Art of Painting*, and his *Notes on the Art of the Low Countries* (the result of a visit to Belgium and Holland in 1781), show a correct and cultivated literary style. He contributed his picture of Miss Morris as 'Hope nursing Love' to the first exhibition of the Royal Academy, along with his portraits of the Duchess of Manchester, Mrs Blake, Mrs Crewe, and Mrs Bouverie; and in 1771 completed his subject of 'Count Ugolino and his Children in the Dungeon,' usually regarded as his most successful effort in the direction of historical art. In 1784 he succeeded Allan Ramsay as painter to the king; in the same year he finished and exhibited his portrait of Mrs Siddons as the 'Tragic Muse,' in the possession of the Duke of Westminster, undoubtedly his greatest portrait, a work existing in several versions, of which one is in the Dulwich Gallery; and in 1787 he undertook three subjects for Boydell's Shakespeare Gallery, executing 'Puck,' 'The Wild Scene from Macbeth,' and 'The Death of Cardinal Beaufort.'

Hitherto he had devoted himself with little interruption to his art, having speedily recovered from a slight attack of paralysis from which he suffered in 1782; but in July 1789 his sight

became affected, and he ceased to paint, though he was still able to enjoy intercourse with his friends. The following year was embittered by an unfortunate dispute with the Academy regarding the appointment of a professor of Perspective, which led to his resignation of the presidentship, a resolution which he afterwards reconsidered and rescinded; and on the 10th of December 1790 he delivered his last Discourse to the students. Gradually his strength sank—for, unknown to his physicians, he was suffering from a painful form of liver complaint—and he peacefully expired on the 23d February 1792.

It is in virtue of his portraits that Reynolds ranks as the head of the English school of art. In the dignity of their style, the power and expressiveness of their handling, the variety and appropriateness of their attitudes, in the beauty of their colouring and the delicacy of their flesh-painting, his portraits have never been surpassed. He was at home alike in portraying the strength of manhood and the grace of the gentler sex; and his pictures of children have an especial tenderness and beauty which have given a world-wide celebrity to works like 'Master Bimbury,' 'The Strawberry Girl,' and 'Simplicity.' His efforts in the higher departments of historical and imaginative art were less successful, and too often these can be regarded only as among the failures of a great artist. In his technical methods Reynolds was unfortunately most careless and uncertain. He was continually experimenting in new processes and nutried combinations of pigments, with the result that even in his own lifetime his works deteriorated, especially in their flesh-tints.

Personally Reynolds was a man of fine and varied culture, and he was distinguished by an exquisite urbanity, the expression of a most amiable and equable disposition, which was exceptionally fitted to win and retain friendship. His dignified gentleness, his mild reasonableness, tamed even the fierceness of Dr Johnson; and there was more of truth than is usual in poetic panegyric in the lines of Goldsmith which speak of this painter as

Still born to improve us in every part,
His pencil on faces, his manners on heart.

The first great collection of the works of Reynolds was brought together by the British Institution in 1813, and numbered 142 pictures; another gathering was formed by the same body in 1823: 154 examples of his art were included in the South Kensington Portrait Exhibition of 1867; and 231 were exhibited in the Grosvenor Gallery in 1883-84. His authentic works have been estimated by Taylor to number between two and three thousand; and from these some 700 engravings have been executed, some of them—such as the mezzotints of J. R. Smith, John Dixon, William Dickinson, Valentine Green, and James M'Ardell—ranking among the finest examples of the art.

The literary works of Reynolds have been published in various editions, including that of Malone, with memoir by Farington (1819), and that of Beechey (1835; now ed. 1890). See Northcote (a pupil of Reynolds), *Memoirs of Sir Joshua Reynolds, Knight* (1813); Leslie and Taylor, *Life and Times of Reynolds* (1865); E. Hamilton, *Il Catalogue Raisonné of the Engraved Works of Reynolds* (1884); the important work by Sir W. Armstrong, *Reynolds* (1900); studies by Lord R. Sutherland-Gower (1902) and W. B. Boulton (1905); J. F. Molloy, *Reynolds and his Circle* (1906); and J. R. Davies, *Reynolds* (with some coloured reproductions, 1913).

Rhabdomancy. See DIVINING ROD.

Rhadamanthus, in Greek Mythology, the son of Zeus and Europa, and brother of Minos of Crete. He settled in Boeotia, where he married

Alemene. So great was his reputation during life for the exercise of justice that after death he was appointed a judge in the under-world, along with Minos and Æacus.

Rhætia, an ancient Roman province embracing a large part of the Alpine tract between the basins of the Po and the Danube, now included in the Grisons and Tyrol. Its inhabitants were brave and turbulent, and were only subdued by Drusus and Tiberius after a desperate resistance. The province was then formed, to which Vindelicia was soon added; but later Rhætia was subdivided into Rhætia Prima and Rhætia Secunda (Vindelicia). The only important town in Rhætia was Tridentinum (*Trent*); the colony of Augusta Vindelicorum (*Augsburg*) was in its northern part.—For the Rhætic Beds, see TRIASSIC SYSTEM.

Rhamnaceæ (*Buckthorns*), a family of dicotyledons, consisting of trees or shrubs; often spiny; with simple, generally alternate leaves, and stipules minute or wanting. There are about 500 known species, natives of temperate and tropical countries, and very generally distributed over the globe. The prevailing principle in the buckthorns is a bitter extractive which is acid or astringent, tonic and anti-febrile. Some of them are used in dyeing (see BUCKTHORN, and FRENCH BERRIES), some in medicine (see RED ROOT), and the fruit of some is pleasant (see JUJUBE); whilst *Horenia dulcis*, a native of China and Japan, is remarkable for the thickening of its flower-stalks after flowering, so as to form a succulent sweet red pulp, with a flavour resembling that of a pear. The lotus of the ancient Lotophagi, celebrated by Homer, is the fruit of *Zizyphus Lotus*, a small shrub abundant in Spain, Sicily, Barbary, Tunis (see LOTUS). The wood of *Rhamnus Frangula* yields a superior charcoal for the manufacture of gunpowder.

Rhampsinitus, a Grecised form of the Egyptian name Ramesses, or Rameses, apparently Ramesses III., the builder of the pavilion of Medinet Abu at Thebes. Of him Herodotus (II., 121 *et seq.*) relates a story substantially the same as one of the most widespread folk-tales of the world. The king built a treasury of stone. The architect left one stone loose, so nicely adjusted as to be unnoticed. Before death he entrusted the secret to his two sons, who plunder the treasure at will, until the elder is caught in a snare. By his desire, the younger brother cuts off and carries away his head, so that he may remain unknown. By further wiles the younger brother continues to outwit the king, and at last marries his daughter.

Such is the oldest recorded version of Asbjörnsen's 'Master-thief' and Campbell's 'Shifty-lad,' Dr Barbu Constantinescu's Rumanian gypsy story of 'The Two Thieves,' a variant of the story of Trophonios and Agamedes in the treasury of Hyriens at Hyria (Paus. ix. 37), of Angeias in Elis, and of Hernes (ἀρχὸς φηλγῆων), as well as of the Hindu legend of Karpura and Gata, or that of Ali Baba and the Forty Thieves in the *Arabian Nights*. The story occurs in the oldest version (12th century) of the romance of the 'Seven Wise Masters,' the *Dolopathos, sire de Rege et Septen Sapientibus*, from which Ser Giovanni probably derived the story as found in his *Pecorone* (written circa 1378), where it is related of an architect named Bindo who stole a golden vase from the treasury of the Doge of Venice. It will be found, more or less perfect, in every collection of European folk-tales, whether Norse, Gaelic, modern Greek, French, Breton, Albanian, Sicilian, Hungarian, Dutch, Tyrolese, Danish, or Russian, as well as Kabyli, Mongolian, Tibetan, and Singhalese.

See Liebrecht's translation (1851) of Dunlop's *History of Prose Fiction*; A. Schiefner in vol. xiv. of the

Bulletin of the St Petersburg Academy of Sciences; W. A. Clouston's *Popular Tales and Fictions* (1887); and Maspero's *Contes Populaires de l'Égypte Ancienne* (3d ed. 1906).

Rhapsodists (Gr., from *rhaptein*, 'to stitch together,' and *odē*, 'an ode'), a class of men in ancient Greece who travelled from place to place reciting poetry. They are distinct from the professional minstrels (*aoidoi*) of the *Odyssey*, although their legitimate successors; but they also seem, at first at least, to have been composers of epic poetry, although it is hardly probable that this was often the case after the 6th century B.C. We find distinct traces of the public recitation by rhapsodists of the Homeric poems as early as 600 B.C., at places so far apart as Sicily, Syracuse, Delos, Chios, Cyprus, and Athens. Indeed at Athens ancient law prescribed the recitation of Homer once every four years at the festival of the Great Panathenaea. To the early rhapsodists mainly belongs the credit of the wide diffusion of the Homeric poems throughout the Greek world. They themselves were held in high esteem and richly rewarded; but in later days the art came to be practised in a mere mechanical manner, and the influence of the rhapsodists ebbed accordingly. In Plato's *Ion* we get a picture of the rhapsodist as he was about the middle of the 4th century B.C. Ion is a native of Ephesus who goes from city to city reciting Homer to crowds of hearers, appearing on a platform in a richly-embroidered dress, a golden wreath on his head. He adds dramatic force to his declamation, and brings Homer home to his hearers' hearts, being himself possessed by Homer. Moreover, he interprets Homer in a continuous exposition, and is proud of his fluency of ideas. Ion is described as devoted exclusively to Homer, but there were a few of his brethren who gave themselves also to Orpheus, Musaeus, Hesiod, Archilochus, or Simonides. It is unlikely that Homer was ever sung to music, although in earlier times there were heroic lays which were sung to the accompaniment of the lyre. As lyric poetry became more distinctly cultivated, such epic lays came to be simply declaimed, the rhapsodist holding a branch of bay in his hand instead of a lyre.

Rhatany, or **RATTANY**, a half-shrubby plant, of the family Leguminosae, a native of the cold sterile tablelands of the Andes in Peru and Bolivia. It is called *Ratanhia* in Peru. It is valued for the medicinal properties of the root, which are shared more or less by other species of the same genus, also natives of South America. In the British Pharmacopoeia the dried roots of two species (*Krameria triandra*, Peruvian Rhatany, and *K. argentea*) are official under the name *Krameria Radix*. The roots vary a good deal in size and thickness, but are always rough-looking, and reddish in colour. The bark has a strongly astringent taste, and when chewed tinges the saliva red; the wood is nearly tasteless. The dried root is a powerful astringent, and is employed in diarrhoea, mucous discharges, passive hæmorrhages, and cases where an astringent or styptic action is indicated. The finely-powdered root is also a frequent constituent of tooth-powders. Rhatany root is imported from various parts of South America, but chiefly from Lima. It is extensively imported into Portugal in order to communicate a rich red colour to wines. Its peculiar properties are due to rhatany-tannic acid, found in the root-bark to the extent of 20 per cent.; it also contains a red colouring matter.

Rhazes, or **RĀZI**, Persian physician and alchemist. See **MEDICINE AND ARAHIA**.

Rhé, ÎLE DE. See **RÉ**.

Rhea, an ancient Cretan earth-goddess, daughter of Uranus and Gaea, wife of her brother the Titan Cronus, and by him mother of the Olympian deities Zeus, Hades, Poseidon, Hera, Hestia, Demeter. She was early identified with the Asiatic nature-goddess Cybele, the Great Mother, who was worshipped on mountains in Mysia, Lydia, and Phrygia. Her Cretan *Curetes* corresponded to the Phrygian *Corymbantes*, many of whom mutilated themselves like Attis in the frenzy of their orgies. The regular priests of Cybele, the Galli, made themselves eunuchs for conscience' sake. A Sibylline oracle decreed the introduction of the worship of the Great Mother at Rome in 204 B.C., and in 217 a temple was dedicated on the Palatine. The cult became widely extended under the Empire. In the 2d century A.D. the rites of the *Tauropolia* and *Criobolia* were added, in which candidates were baptised for purification and regeneration with the blood of sacrificial bulls and rams. See the article **CYBELE**. **RHEA SYLVIA** was the mother of Romulus (q.v.).

Rhea, or **NANDU**, or **SOUTH AMERICAN OSTRICH**, a genus of Ratite birds, differing from the ostriches of the Old World in having three toes with compressed nails, fully feathered head and neck, proportionally larger wings, and no conspicuously feathered tail. The feathers have no aftershaft. The Rheas live chiefly on the open plains, and are predominantly vegetarian; they run very swiftly and swim well. They are polygamous, and the male incubates the twenty to thirty eggs which his hens lay. The eggs of *Rhea americana* (from Southern Brazil and Bolivia southwards), fourteen to twenty-four, are golden yellow, those of *R. darwini* (from the southern part of the continent) deep green, but both kinds fade into white. There is a third species, *R. macrorhynchos*, from north-east Brazil. Rheas are readily acclimatised, and will breed in Europe. See Hudson, *Argentine Ornithology* (1889).

Rhea Fibre. See **BOEMERIA**.

Rhegium. See **REGGIO**.

Rhegius, **URBANUS** (1489-1541), reformer, born at Langenargen, Lake of Constance, was professor of Poetry and Rhetoric at Ingolstadt, and cathedral preacher at Augsburg, where he preached Lutheran doctrines and wrote satires. Later he removed to Celle.

Rheims. See **REIMS**.

Rheinberger, **JOSEF** (1839-1901), composer, was born at Vaduz, Liechtenstein, and early showed a marked aptitude for music. In 1851 he became a student and in 1859 a professor at the Munich Conservatorium. He lived at Munich till his death. A thorough and conscientious teacher, he was also a prolific composer along traditional lines, chiefly in the domain of choral music, but only a few of his twenty organ sonatas have survived.

Rheingau, a district, 14 miles long, stretching along the right bank of the Rhine, from opposite Mainz to the village of Lorch, 8 miles below Bingen, formerly belonged to the archbishopric of Mainz, and now forms part of the administrative district of Wiesbaden in Prussia. Protected by mountains from the north and east winds, and exposed to the mid-day sun, the Rheingau produces wines of the best quality, as Johannsberger, Rüdesheimer, Marcobrunner, Assmanshäuser, &c.

Rheinland, also called Rheinprovinz, Rheinpreussen, Rhénish Prussia, the westernmost and (except the city of Berlin) the most thickly peopled of the provinces of Prussia, lies on both sides of the Rhine and the Lower Moselle, and is bounded on the W. by Luxembourg, Belgium, and the Netherlands. The southern end forms, with part

of Bavaria, the Saar Territory, placed by the Treaty of Versailles under the League of Nations till 1935, when it is to decide its future by plebiscite. The same treaty assigned some 400 square miles to Belgium (Eupen and Malmedy). Area of province 10,048, including 5/4 in the Saar region. Pop. (1885) 4,344,527; (1890) 4,710,313; (1910) 7,120,519; (1925) 7,250,195, not including the Rhenish Prussian part of the Saar Territory, which had in 1922 622,418 inhabitants. The capital is Coblenz. The surface is more or less mountainous, except in the extreme north, reaching 2500 feet on the west of the Rhine, but only 1800 on the east side. The soil of the higher tracts is not very fertile, and is largely forest land; but the valleys of the Rhine, Moselle, and Nahe are very fruitful, and so are the flat districts in the north. Of the total area, two-thirds is cultivated, including meadows and vineyards, and nearly one-third under forest. Grain, potatoes, beet-root, tobacco, hops, flax, &c. are the more important crops. Much wine and large quantities of vegetables are grown. Coal, iron, and lead are mined. The sulphur-springs of Aachen and Bartscheid have a European reputation. Industry and manufactures are prosecuted with the greatest energy and success, this province ranking first in all Prussia in this respect. It is enough to name some of its towns: Cologne, Elberfeld-Barmen, Düsseldorf, Crefeld, Duisburg, Essen, Muenen-Gladbach, Aachen. There is a university at Bonn. This province was formed in 1815 out of the duchies of Cleves, Jülich (Juliers), Guelders, and Berg, and numerous minor territories. The Treaty of Versailles provided that most of Rheinland should be occupied by the Allies, to be evacuated by various dates down to 1935. A separatist movement fomented by France ended in fiasco. The Ruhr (q.v.) basin was occupied later by the French.

Rhenish Architecture. the style of the countries bordering on the Rhine when the arts first revived after the fall of the Roman empire.

They and Lombardy being at the time of Charlemagne part of the same empire, Lombard Architecture (q.v.) has considerable affinity with that north of the Alps. Some very early examples of this style are still to be found in Switzerland. Architecture received great encouragement from Charlemagne and his successors, and the Rhenish style made great progress up to the beginning of the 13th century, when the fashion of copying the Gothic architecture of France superseded it. It is, however, a well-marked style, and is complete and perfect in itself. Like the Lombard style, it is round-arched, and has some remarkable peculiarities. Many of the earliest churches seem to have been circular (like the cathedral at Aachen, built by Charlemagne), but in course of time the circular church was absorbed into the Basilica, or rectangular church (see ROMANESQUE ARCHITECTURE), in the form of a *western apse*. Most German churches thus have *two apses*—an eastern and a western. They also have a number of small circular or octagonal towers, which seem to be similar in origin to the Round Towers (q.v.) of Ireland. They exemplify in a remarkable manner the arrangements of an ancient plan of the 9th century, found in the monastery of St Gall, and supposed to have been sent to the abbot, as a design for a perfect monastery, to aid him in carrying out his new buildings. The arcaded galleries at the eaves, and the richly-carved capitals, are among the most beautiful features of the style. Examples are very numerous from about 1000 to 1200 A.D. The three great specimens of the style are the cathedrals of Mainz, Worms, and Speier. The last is a magnificent building, 435 feet long by 125 feet wide, with a nave 45 feet wide, and 105 feet high. It is grand and simple, and one of the most impressive buildings in existence. There are also numerous fine examples of the style at Cologne—the Apostles' Church, St Maria im Capitol, and St Martin's being amongst the most finished

Fig. 1.—Plan of Church at Laach.

Fig. 2.—Elevation of Church at Laach.

examples of Rhenish architecture. The illustrations of the famous church of the Benedictine abbey at Laach, near Coblenz, explain the peculiarities of plan and elevation above referred to. The vaults in this case being small, the different spans were

managed (although with round arches) by stiling the springing; but in great buildings like Speier and Worms the vaults are necessarily square in plan, in this round-arched style, and the nave embraces in each of its bays two arches of the side

aisses—a method also followed by the early Gothic architects. From the use of the round arch and solid walls, the exteriors are free from the great mass of buttresses used in Gothic buildings, and the real forms are distinctly seen (see APSE).

Rhenish Prussia. See RHEINLAND.

Rhenium, an element (Re), of atomic number 75, whose discovery by Drs Walthier Wonnack and Eva Tacke was announced in 1925.

Rheostat, the name given by Wheatstone to an instrument for varying an electric resistance between given limits. In Kelvin's form a platinum or platinoïd wire is wound round two parallel cylinders, one of which is metal and the other of some insulating material. In any position the part of the wire which is effective as a resistance is the part that is on the insulating cylinder up to where it comes in contact with the metal cylinder. By means of a gearing of toothed wheels and screw shaft the two cylinders are turned simultaneously in one or the other direction, while at the same time a nut travels to or fro and guides the wire as it leaves the one cylinder and coils itself round the other. See ELECTRICITY.

Rhesus Monkey, or BOONDER (*Macacus rhesus*), a widely distributed and common Indian monkey. Like the Entellus (q.v.) or Hanuman, it is in part migratory, visiting the Himalayas in summer, and sometimes found at a level of 8000 feet. The body is stout, the limbs are strong, the skin hangs in loose folds about the neck, breast, and abdomen. The hair is grayish or brownish on the back and lighter beneath; the naked parts are copper-coloured; the large ischial callosities are bright red. It is a very intelligent and mischievous monkey, and readily tamed when young. It is

Rhesus Monkey (*Macacus rhesus*)

held in almost as great veneration by the natives of India as the Hanuman itself; and the killing of one of these animals is apt to arouse the greatest popular indignation. The monkeys live in troops in the forests, chiefly in hilly districts, and visit the cultivated grounds to carry away grain and other produce, which they store up for themselves among rocks. The native farmers leave a share for the monkeys, believing this to be necessary to avert their anger, as otherwise they would next year destroy the whole crop whilst given.

Rhetoric (Gr. *rhêtorikê*) in its broadest sense may be regarded as the theory and practice of eloquence, whether spoken or written. It aims at

expounding the rules which should govern all prose composition or speech designed to influence the judgments or the feelings of men, and therefore treats of everything that relates to beauty or force of style, such as accuracy of expression, the structure of periods, and figures of speech. But in a narrower sense rhetoric concerns itself with a consideration of the fundamental principles according to which particular discourses of an oratorical kind are composed. The first to reduce oratory to a system were the Sicilian Greeks; its actual founder is said to have been Corax of Syracuse (c. 500 B.C.). He divided the speech into five parts, proem, narrative, arguments, subsidiary remarks, and peroration; and he laid great stress on the rhetorical capabilities of general probability. Later masters of rhetoric were Tisias; Gorgias of Leontini, whose style was burdened with too much ornament and antithesis; Antiphon, the earliest of the so-called 'Ten Attic Orators,' and the first writer of speeches for others to deliver in court. The speeches given by his great pupil Thucydides throughout his history, and the orations of Andocides, second of the Ten, are severely free from the florid ornament of later days. Lysias was an orator rather than a rhetorician; Isocrates first thoroughly taught rhetoric, which he defined as the 'science of persuasion,' as a technical method and discipline. His most celebrated pupils were Hyperides, Speusippus, and Isenias. The great Demosthenes was a pupil of the last. His opponent Æschines, and his contemporaries Hyperides, Lycurgus, and Dinarchus complete the Ten. Anaximenes of Lampsacus composed the oldest extant manual of rhetoric, but the great classical work on this subject is the analytical masterpiece of Aristotle. According to him its function is not to persuade, but to discover the available means of persuasion in any subject. He regards it as the counterpart of logic, and arranges its uses as (1) the means by which truth and justice assert their superiority to falsehood and injustice; (2) the only method of persuasion suitable to popular audiences; (3) a means of seeing both sides of a case and of discerning the weakness of an adversary's argument; (4) as a means of self-defence. The means of persuasion he groups in two classes: (1) the inartificial proofs, such as statements of witnesses, contracts, and the like; (2) the artificial proofs, whether these are (a) *logical*, demonstration or seeming demonstration by argument; (b) *ethical*, when the speaker induces confidence by the weight of his own character; or (c) *emotional*, when he works persuasively on the feelings of his hearers.

Of these artificial proofs, first comes the *logical*, and this depends on the *enthymeme*, 'a syllogism from probabilities' and signs; next is the example. Of the materials of enthymemes, the topics or commonplaces of rhetoric, Aristotle distinguishes between the *common*, general heads applicable to all subjects as to their possibility or impossibility, and the *special*, those drawn from special arts or faculties.

He divides the three provinces of rhetoric thus: (1) *Deliberative* rhetoric, concerned with exhortation or dissuasion, and future time, its ends expediency and inexpediency; (2) *Forensic* rhetoric, concerned with accusation or defence, and with time past, its ends justice and injustice; (3) *Epidictic* rhetoric, concerned with eulogy or censure, and usually with time present, its ends being honour and disgrace, or nobleness and shamefulness. In his first two books Aristotle deals with *invention*, the discovery of means of persuasion; in the third, with *expression and arrangement*; and he begins the subject by discussing the art of *declamation or delivery*. Under verbal expressions he discusses the use of metaphor, simile, proverbs, rhythm, and

variety of styles, as the *literary* and *controversial*, whether the *political* or the *forensic*.

Aristotle's method dominated the Peripatetic school, but later began to be modified by the florid influence of Asia, the originator of which was Hegesias of Magnesia. The school of Rhodes followed more closely Attic models, and gained great fame through its conspicuous leaders Apollonius and Molon (c. 100-50 B.C.). Hermagoras of Temnos (c. 120 B.C.) composed an elaborate system which long retained its influence. Later rhetoricians were Dionysius of Halicarnassus, Longinus, Hermogenes, Apsines, Menander, Theon, and Aphthonius. Among the earliest Roman orators were Appian Clandius Cereus (c. 300 B.C.), Cato the Censor, Ser. Sulpicius Galba, Cains Gracchus, Marcus Antonius, and Lucius Licinius Crassus. The instructors in formal rhetoric were Greek, and the great masters of theoretical and practical rhetoric alike, Cicero and Quintilian, were both trained by Greek models. The former contributed to a discussion of its theories no less than three treatises, *De Oratore*, the *Brutus*, and the *Orator*; the latter's famous *Institutio Oratorum* still retains its value. Quintilian strove hard to reform the taste of the time, which had become Asiatic through exclusive attention to the form and perpetual exercises in the schools on imaginary subjects—the *suasoria* and *controversia* of the elder Seneca. The *Dialogus de Oratoribus*, long ascribed to Tacitus, was another protest against modern fashion. The younger Pliny's *Panegyric* long remained a model to later orators. During the first four centuries of the empire rhetoric continued to be taught by 'sophists' at Athens, Smyrna, Rhodes, Tarsus, Antioch, Alexandria, and Massilia. These were in most esteem under Hadrian, the Antonines, and Marcus Aurelius—among the most celebrated were Theodotus, Polemon, and Adrian of Tyre. Throughout the middle ages rhetoric formed one of the subjects of the *trivium*; its leading authorities were Martinus Capella, Cassiodorus, and Isidorus. The subject re-awoke with the revival of learning, and was taught regularly in the universities, the prescribed public exercises and disputations keeping it long alive; but in later generations it has constantly languished, in spite of more or less laborious or effective attempts to fan it into life by the sententious Blair, the solid Campbell, and the sagacious Whately. In America, however, considerable attention is paid to it as a branch of general education.

Rheumatism (from the Gr. *rheuma*, 'a flux') is a term which has been, and still is, rather vaguely and extensively used in the nomenclature of disease. But there is one very definite affection to which it is always applied; after this has been discussed the other senses in which it is used will be considered.

Acute rheumatism or *rheumatic fever* is indicated by general febrile symptoms, with redness, heat, swelling, and usually very intense pain, in and around one or more (generally several, either simultaneously or in succession) of the larger joints, and the disease shows a tendency to shift from joint to joint or to certain internal serous membranes, especially the pericardium and the endocardium; rheumatism being the most common origin of pericarditis, as has been already shown in the article on that disease. The pulse is strong and full, there is headache, but seldom delirium, unless in very severe cases; the tongue is covered with a creamy thick fur, the tip and edges being red; the urine is turbid, and abnormally acid; and the skin is bathed in a copious perspiration, with so characteristic a smell (resembling that of sour milk) that the physician can often recognise the disease

almost before he sees the patient. The joints are extremely painful, and the pain is much increased by pressure, and consequently by movement which gives rise to internal pressure. Hence the patient lies fixed in one position from which he dares not stir.

The usual exciting cause of acute rheumatism is exposure to cold, and especially to cold combined with moisture, and hence the greater prevalence of this disease amongst the poor and ill-clad. Sleeping in damp sheets or upon the damp ground, the wearing of wet clothes, and sitting in a cold damp room, especially if the sitter was previously warm from exercise, are examples of the kind of exposure which is apt to be followed by this disease. Rheumatism is not, however, a universal sequence to exposure to the cold. It only occurs when there is a special predisposition, or, as it is termed, a rheumatic diathesis or constitution, and the diathesis may be so strongly developed as to occasion an attack of acute rheumatism, independently of exposure to any apparent exciting cause. Acute rheumatism is often associated with Chorea (q.v.); but the exact nature of the relation between the two is not known. Scarlet fever is the only other disease which seems specially liable to be followed by acute rheumatism. Men are more subject to the disease than women, but this probably arises from their greater exposure to atmospheric changes on account of the nature of their occupations. The predisposition is certainly affected by age; children under ten years being comparatively seldom attacked, while the disease is most prevalent between the ages of fifteen and forty. Above this age a first attack is rare, and even recurrences are less frequent than earlier in life. Persons once affected become more liable to the complaint than they previously were. The disease is hereditary in a considerable proportion of cases; and even when it cannot be traced, in previous generations the predisposition is very apt to exist in several members of the same family. The actual cause of the disease is probably microbial, and many cases have been traced to the '*Micrococcus rheumaticus*,' though often this cannot be discovered, and other organisms may be responsible.

In the great majority of cases acute rheumatism ends in recovery; and permanent damage to the affected joints is rare. It is, however, extremely apt to recur, either in the early stages of convalescence, or after an interval of months or years. The chief danger arises from implication of the heart, which very frequently occurs; probably in about one-half of those suffering for the first time either the pericardium or endocardium or both are affected. The younger the patient the greater the liability to these complications, which usually result in more or less permanent impairment of the heart's action (see HEART, PERICARDIUM). Another condition, much less common, but extremely fatal, is known as *rheumatic hyperpyrexia*, and is characterised by a very rapid rise of temperature to 108° or 110°, with head symptoms in the form either of drowsiness or of violent delirium.

The patient should be strictly confined to bed between blankets (i.e. without sheets), and be clothed in flannel; he must be carefully protected from draughts, and from undue pressure of the bed-clothes, and supplied with light nourishment and diluent drinks. Under such conditions, without other treatment, most cases recover in the course of time. Till the last quarter of the 19th century there was no general agreement as to what more should be done. When bleeding was used for most acute diseases this one was no exception. When that practice was abandoned numerous drugs were used, in some cases with apparent success. Quinine, iron, lemon juice, colchicum, large blisters to all the

affected joints, were all recommended; more in favour than any of these were alkalis in large doses. But in 1876 Stricker in Berlin and MacLagan in England called attention to another method of treatment which is now almost universally adopted. Though new to Europe it has long been in use elsewhere, for the natives of South Africa have from time immemorial treated the disease by willow-top infusion. This method consists in the administration of Salicin (q.v.), or one of its derivatives (salicylic acid, salicylate of soda, &c.). The last is at present most largely used. It is usually given in doses of 15 or 20 grains, together with bicarbonate of soda, every two or three hours at first; but its action needs to be carefully watched, as it often causes considerable depression, deafness, and other uncomfortable symptoms. It has a remarkable effect in reducing the fever and relieving the pains; but under this treatment, as without it, relapses are frequent. In rheumatic hyperpyrexia the only treatment that has been found effectual is sponging, or immersion in a tepid bath as often as the temperature rises to a dangerous point. Convalescence is usually very slow, and it is necessary to keep the patient in bed and on low diet for some time after the fever has disappeared to diminish the tendency to relapse. At this stage tonics, especially quinine and iron, are generally useful.

Chronic Rheumatism.—Chronic painful affections of the joints sometimes follow rheumatic fever and sometimes occur without it. The name is often erroneously applied to chronic and insidious forms of gout. There is another form of disease to which most of the cases of so-called 'chronic rheumatism' belong, which deserves separate mention.

Osteo-arthritis (chronic rheumatic arthritis and rheumatoid arthritis are among its many other names) is characterised in most cases by a very chronic course, by pain and stiffness in one or more of the joints, with creaking on movement, and by destructive changes of the cartilages of the affected joints, with enlargement of the ends of the bones in their neighbourhood. It is more common in women than in men; most often begins at or after middle life, though occasionally even in childhood; and is apt to affect those who are weakly and who have had a life of hard work with defective nourishment. There is no special liability to affection of the heart as in true rheumatism. In the treatment of this ailment hot baths and douches, particularly with certain mineral waters (e.g. those of Bath, Aix les-Bains), and a warm dry climate are very valuable; a generous diet is essential. Of drugs, cod-liver oil and arsenic are most often serviceable; but many others, such as sulphur, especially in the colloidal form, fibrolysin, &c., are of use. The exposure of the affected joints in a hot-air bath, or to a powerful galvanic current is often very helpful. Under any treatment, however, complete recovery is exceptional; but the disease, even when severe, does not much shorten life.

Gonorrheal rheumatism is a form of joint-disease closely simulating acute rheumatism which occurs in some cases of Gonorrhea (q.v.). The affection does not, however, fit from joint to joint in the same way, and is not amenable to the same treatment.

Muscular rheumatism is the name usually given to painful affections of the muscles for which no clear cause is discoverable; it usually depends either on localised muscular spasm or imperfect excretion of waste products from the system. Eliminating treatment, by alkalis, purgatives, or diaphoretics, is usually indicated, and pain is relieved by local application of heat, belladonna plasters, &c.

RHEUMATIC DISEASES OF ANIMALS.—These are less common than the corresponding affections of men. Horses are not very liable to acute rheumatism, but suffer from a chronic variety, which occurs especially in conjunction with influenza. When affecting the limbs it often exhibits its characteristic tendency to shift from one part to another. In cattle and sheep rheumatic disorders are more common and acute than in horses. The specific inflammation sometimes involves most of the fibrous and fibro-serous textures throughout the body, inducing general stiffness, constipated bowels, and high fever. This is rheumatic fever—the chine-felon or body-garget of the old farriers. Sometimes the disease mainly affects the larger joints, causing intense pain, lameness, and hard swellings; occasionally it is confined to the feet and fetlocks, when it is recognised as bastian-foul. Cattle and sheep on bleak exposed pastures, and cows turned out of the dairy to feed on strong alluvial grazings are especially subject to rheumatism in its several forms. Amongst dogs rheumatism is known under the name of kennel lameness, and is very troublesome and intractable in low, damp, cold situations. Blood-letting is rarely admissible except in the most acute cases amongst cattle. In all animals a laxative should at once be given, with some saline matters and colchicum, and when the pain and fever are great a little tincture of aconite may be added. For cattle a good combination consists of one ounce of nitre, two drachms of powdered colchicum, and two fluid drachms of the Pharmacopoeia tincture of aconite, repeated in water or gruel every three hours: half this dose will suffice for horses. With a simple laxative diet dogs should have a pill night and morning containing five grains of nitre and two of colchicum. Comfortable lodgings, a warm bed, horse-rings on the body, and bandages on the legs will greatly expedite a cure. In chronic cases, or after the more acute symptoms are subdued, an ounce of oil of turpentine and two drachms each of nitre and powdered colchicum should be given for a cow, half that quantity for a horse, and one-fourth for a sheep. Hartshorn and oil, or other stimulating embrocations, diligently and frequently rubbed in, will often abate the pain and swelling of the affected joints.

Rheydt, a town of Rheinland, 19 miles by rail W. by S. from Düsseldorf, has manufactures of silks, velvets, cottons, machinery, hardware, paper, dyeworks, and breweries. Pop. 43,000.

Rhigas, KONSTANTINOS (1760-98), Greek poet, translator, and agitator, born at Velestinos, organised the revolutionary movement among the Greeks at Vienna, but was betrayed to the Turkish authorities and shot at Belgrade.

Rhin, BAS and HAUT, until 1871 frontier departments of France, corresponded pretty nearly to Lower and Upper Alsace. Since the Treaty of Versailles they have been revived. See ALSACE-LORRAINE; also BILFORT.

Rhine (Ger. *Rhein*, Fr. *Rhin*, Dutch *Rijn*, Lat. *Rhenus*), in every way one of the most important rivers of Europe. A large number of rivulets, issuing from glaciers, unite to form the young Rhine; but two are recognised as the principal sources—the Neerer and the Farther Rhine. The former emerges on the north-east slope of the Gott-hard knot (7690 feet above sea-level), and only a dozen miles from the cradle of the Rhine, on the other side of the same mountain-knot; the Farther Rhine has its origin on the flank of the Rheinwaldhorn (7270 feet), not far from the Pass of Bernardino. The two mountain-torrents meet at Reichenau, 6 miles SW. of Coire (Chur) in the Grisons canton, after they have descended, the

Nearer Rhine 5767 feet in 28 miles in a north-east direction, the Farther Rhine 5347 feet in 27 miles along a northerly course. At Coire the united stream strikes due north for 45 miles, and, separating the canton of St Gall from Liechtenstein and Vorarlberg, enters its clearing basin, the Lake of Constance (1306 feet above the sea). It leaves this lake at its north-western extremity, a little below Constance, its water a deep transparent green, and flows generally westwards, in three or four wide curves, to Basel, separating Baden on the north from Switzerland on the south. Along this stretch the river (490 feet wide) plunges down the falls of Schaffhausen, nearly 70 feet, in three leaps, and races over narrow rapids at three separate places where the terminations of the Jura Mountains intrude into the bed of the river; from the left it receives the more copious waters of the Swiss Aar. Basel is 280 miles distant from the source of the Nearer Rhine following the windings of the channel, but only 85 miles as the crow flies.

At Basel (742 feet) the river, now 225 yards wide, wheels round to the north, and, traversing an open shallow valley that separates Alsace and the Bavarian Palatinate from Baden, reaches Mainz (50° N. lat.) in Hesse-Darmstadt, north-north-east from Basel. This valley is fenced in by the Black Forest on the east and by the Vosges on the west; in it stand the cities of Mülhausen, Colmar, Strasburg (on the Ill, 2 miles from the Rhine), Germerheim, Speier, Ludwigshafen, and Worms, all on the left side, and Freiburg, Baden, Rastatt, Carlsruhe, Mannheim, Heidelberg, and Darmstadt on the opposite side of the river. Along this section the Rhine splits into many side arms that flow parallel to the main stream, and is studded with green islands. Navigation, however, which begins at Basel (although boats ply for short stretches on the upper waters above that point, even as high as Coire) is facilitated by artificial means, in that the current is made to flow in a carefully-kept, straightened channel. Of the numerous affluents which add their waters to the volume of the Rhine along this section the largest are the Neckar and the Main, both coming from the right, and both navigable; the Ill, which falls into it from the left, is also navigable. A little below Mainz the Rhine (685 yards wide) is turned west by the Taunus range; but at Bingen it forces a passage through, and pursues a north-westerly direction across Rheinland, past Coblenz, Bonn, Cologne, Düsseldorf, Ruhrort, and Wesel as far as the Dutch frontier, which it reaches a little below Emmerich, and opposite Cleves; here it is 1085 yards wide and 36 feet above sea-level. The first half of this portion of the river from Bingen to Bonn is the Rhine of song and legend, the Rhine of romance, the Rhine of German patriotism. Its banks are clothed with vineyards that yield wine esteemed the world over (see below); the rugged and fantastic crags that hem in its channel are crowned by ruined castles; the treasure of the Nibelungs rests at the bottom of the river, but higher up, at Worms; the Bingerloch (see BINGEN) and the Mouse Tower of Bishop Hatto, the fortress of Ehrenbreitstein, the rock of the siren Lorelei, the commanding statue of Germania (the trophy of German victory in 1870), and innumerable other features lend interest to this middle course of 'Father Rhine,' as his German children call him. It still inspires them as in 1870, when Max Schneckenburger's *Wacht am Rhein* (written in 1840; the music by K. Wilhelm, 1854) was sung by them with the greatest enthusiasm as they poured into France. There is the *Rheinlied*, too, of Nikolaus Becker, with Alfred de Musset's retort, *Nous l'avons eu, votre Rhin allemand* (1841). Between Bingen and Bonn the steep rocky walls

that fence in the river approach so closely together that in many places the road and the railway have to find a way through tunnels. The Nahe enters the Rhine at Bingen, the Moselle at Coblenz; from the opposite (right) side the Lahn enters just above Coblenz. Below Bonn it is joined by the Sieg, Wupper, Ruhr, and Lippe, all from the right.

At Bonn the river enters the plains, and almost immediately after passing the Netherlands frontier its delta begins. The principal arm, carrying two-thirds of the volume, flows under the name of the Waal, and later the Mermede, due west past Nimègue until it reaches Dordrecht. East of the Biesbosch it picks up the Maas (Mense) from the left. At Dordrecht the river again divides, one branch, the old Maas, running out to sea; the other, the Noord, going up north-west to Rotterdam, just above which town it is joined by the Lek, another main arm of the deltaic complex, and below which town it once more unites with the Old Maas. The arm that strikes off northward at the point where the delta begins soon divides, sending one branch, the Yssel, due north to the Zuider Zee, which it reaches on the east side near Kampen; the other branch is the Lek, which runs into the Waal-Maas arm above Rotterdam. A thin stream called the 'Winding Rhine' leaves the Lek half-way between Arnhem and Rotterdam; but it again splits at Utrecht into two channels, of which the Old Rhine, a mere ditch, comparatively speaking, manages with the help of a canal and locks to struggle into the North Sea at Katwyk, a little to the north-west of Leyden, while the other channel, the Vecht, flows due north from Utrecht until it enters the Zuider Zee, a short distance from Amsterdam. For considerable distances in these delta regions the rivers are only kept from overflowing the country by artificial banks or dykes.

The area drained by the Rhine is estimated to be 75,773 sq. m., and its total length to be 760 miles, of which 550 in all are navigable. The Rhine-Main-Danube Canal, to carry great ships from the North Sea to the Black Sea, was begun in 1921, the old Ludwigskanal being inadequate. The Rhine and Rhine Canal unites it with the Rhone, and so with the Mediterranean; another canal provides a waterway between it and the Marne, a tributary of the Seine; and yet a fifth unites it with the Zuider Zee at Amsterdam. The fisheries are of considerable importance; salmon, carp, pike, sturgeon, and lampreys—the fish of greatest value—are taken principally near St Gaur, between Bingen and Coblenz.

Commercially and historically the Rhine is one of the principal rivers of Europe. It was the Romans' strongest bulwark against the Teutonic invaders. The Romans, and after them the Franks, encouraged commerce to travel up and down its waters, and kept its channel open. Under Charlemagne the ravages caused by the Teutons having broken through the Roman guard along the Rhine and inundated Gaul were rapidly obliterated, and the Rhine valley became the principal focus of civilisation in the early empire. Except between 1697 and 1871, and since 1919, the Rhine was always a German river; at the peace of Ryswick, Alsace-Lorraine was appropriated by France, and the Rhine became part of the dividing line between France and Germany. In 1801 Napoleon incorporated the whole of the left bank with France; in 1815 the arrangement in force before 1801 was restored; and after 1871 the Rhine became once more wholly German; but Alsace-Lorraine was lost by the war of 1914-19. From the days of the Roman supremacy down to the beginning of the 19th century navigation was always more or less hampered by the riparian sovereigns, during the greater part of the time a large number of

duodecimo princelings, who levied vexatious dues on the shipping that sailed up and down past their towns and territories. From 1803 all the powers concerned, except Holland, abolished most of the shipping dues on their own vessels navigating the Rhine, and Holland followed suit in 1831; but it was not until 1st July 1869 that the river was declared an absolutely free waterway to the ships of all nations. The first steamboat churned up its waters in 1817. There have been various schemes for utilising the mechanical power of the Rhine current by means of turbines and electro-motors. For the political organisation (1805-13) taking its name from the Rhine, see CONFEDERATION OF THE RHINE.

RHINE-WINE indicates, strictly speaking, the wines produced in the Rheingau (q.v.), the most valued and costly being those of Castle Johannisberg, Hochheim (whence the word *Hock*, applied in England promiscuously to all white Rhine wines), Rüdesheim, Steinberg, Gräfenberg, Rantenhal, Maubrunn, Assmannshausen, and Geisenheim. Except the wine of Assmannshausen (Assmannshäuser), which is red, these wines are of a white or light golden colour, and have an exquisite bouquet and a dry piquant flavour. In a wider sense the term Rhine-wine includes the wines of nearly all the valleys lying contiguous to the Rhine—those of Baden, Alsace, the Moselle, Hesse-Nassau, and the Palatinate.

See the illustrated *Rhine*, by Stieler (trans. 1878); the guide-books of Murray and Baedeker; Smorock's *Rheinsagen und Das malerische und romantische Rheinland*; the history of the river by Mehlis (1876-79); *A Book of the Rhine*, by Baring Gould (1906); *The Rhine, its Valley and History*, by Sir H. J. Mackinder (1908); and *Tausend Jahre deutscher Geschichte und deutscher Kultur am Rhein* (ed. Aloys Schalte, 1925).

Rhinoceros, a genus representing a distinct family of ungulate mammals, contains only five distinct species, unless *R. lasiotis* be recognised. These five species are distributed in the hotter parts of the Old World as follows: Africa contains two forms, which are often called the 'Black' and the 'White' rhinoceros. These terms are, however, very inapt, since both of them are of a grayish black; in colour there is but little difference between *R. sinas* and *R. bicornis*. They may, however, be distinguished by other points—the first species is much larger, and has a flat nose and square upper lip, while *R. bicornis* has the upper lip prolonged so as to enable it to seize and break off branches. Correlated with this structural difference is one of habit: *R. sinas* grazes, while *R. bicornis* feeds chiefly upon shrubs. A number of other species have been stated to occur in Africa, but it appears that these 'species' have been for the most part founded upon unimportant differences in the length of the two horns with which these animals are furnished. In Asia there are at least three well marked species of rhinoceros. The large one-horned species, *R. unicornis*, occurs only in Nepal, Bhutan, and Assam; it is a very big species. A specimen in the Zoological Society's Gardens measured over 10 feet in length and a little more than 5 feet in height at the shoulder. It has enormous folds of skin, which give it the appearance of being 'armour-plated.' The African species have a smooth, though of course very thick, skin. The second Asiatic rhinoceros is *R. sondaicus*, which is smaller than the last, though also one-horned; it occurs in Java, Borneo, and the Sundarbans near Calcutta. The two-horned Asiatic rhinoceros (*R. sumatrensis*) is found in Malacca, and *R. lasiotis*, from Chittagong, eastern Bengal, is hardly separable from it. Rhinoceroses were more abundant in earlier periods of the earth's history than they are at present;

one form (*Aceratherium*) existed without the characteristic horn or horns, while another (*Dicraetherium*) had the horns placed side by side instead of following each other. The gigantic Miocene or Oligocene primitive hornless rhinoceros *Baluchitherium*, discovered in 1922, seems to have been the biggest mammal known, some 13 feet high at the shoulders. Its fossil remains are found in Beluchistan, Turkestan, and Mongolia. The animals are now a waning race. Sir Henry Johnston, writing of the white rhinoceros in 1924, says: 'In the course of some eighty years British and Boer "sportsmen" have steadily shot it down, wherever it could be got at, between the South-West Congo frontier, Zululand, and the Zambesi; and again in the equatorial regions of Africa—Uganda and the lands of the Southern Bah-el-Ghazal and the White Nile—with the result that scarcely more than a hundred examples of this interesting, harmless monster now survive. The greater number of these survivors still live along the south-west limits of the Bah-el-Ghazal and the adjoining fringe of the Congo basin, under French and Belgian rule. There it was rediscovered by Colonel Roosevelt's expedition. Its numbers in the British Sudan were estimated some five years ago "at between 2000 and 3000." Appar-

Rhinoceros unicornis.

(From a Photograph by Gambel Bolton, F.Z.S.)

ently, after Roosevelt's rediscovery of the animal, the Sudan government of those days had sufficient soul and knowledge to place it on the list of protected beasts. Recently, however, the blood lust seized their officers again, protection was seemingly removed or shootists mocked at the laws, and big-game sportsmen and natives combined have in five years almost exterminated the wonderful beasts. The French and Belgians, unhappily, are not, as nations, nearly so keenly interested in zoology as are we and the Americans; for we combine both the good qualities and the sheer vices of an interest in beasts and birds. Neither the French, therefore, nor the Belgian administrators of the Congo basin have put any effective obstacle in the way of British shootists afflicted with this blood lust. The case of Natal pushes itself into equal prominence with the British misdeeds in the Sudan. Dr Hornaday dwells on the outrages of a Natal "game butcher"—unhappily with an English surname who seemingly under a permit of the Natal government, has recently gone into the Zululand Game Reserve and slaughtered four out of the twenty remaining white rhinoceroses. The first rhinoceros seen in Europe since the days of the Roman amphitheatres was an Indian one sent to Emmanuel of Portugal. *Notes and Queries* (January 1912) recorded the presence of one in London in 1684. Accounts as to the character of the rhinoceros differ very pointedly. Some describe them as blundering and very stupid

animals, others as exceptionally fierce and cunning (fiercer than tigers). Perhaps they are sometimes in one humour, sometimes in another. The white rhinoceros is said to be 'perfectly harmless.'

The rhinoceros, with the horse and tapir, forms the Perissodactyl division of the Ungulata (q.v.). The Asiatic rhinoceroses are distinguished from the African forms by the presence throughout life of functional incisor teeth; and in other (osteological) characters the African species are to be contrasted with the Asiatic; in spite of its two horns, *R. sumatrensis* is more closely allied to *R. unicornis* than to *R. bicornis*; even the fossil species are referable for the most part to one or the other group. The Siberian *R. tichorhinus*, of which a specimen, partly preserved through its being frozen, was found by Pallas, belongs to the African group, which is sometimes separated under the generic name of *Atelodius*.

Rhinoplastic Operations. When a portion or the whole of the nose has been destroyed by accident or disease, the deficiency may be restored by a transplantation of skin from an adjoining healthy part. When the whole nose has to be replaced, the following course is usually adopted. A triangular piece of leather or gutta-percha is cut into the shape of the nose, and is extended on the forehead with its base uppermost; its boundaries, when thus flattened, are marked out on the skin with ink. Any remains of the old nose are then pared away, and a deep groove is cut round the margins of the nasal apertures. When the bleeding from these incisions has stopped, the marked portion of the skin of the forehead must be carefully dissected away, till it hangs by a narrow strip between the eyebrows. When the bleeding from the forehead ceases, the flap must be twisted on itself, so that the surface which was originally external may remain external in the new position, and its edges must be fastened with stitches into the grooves prepared for their reception. The nose thus made is to be supported with oiled lint, and well wrapped in flannel to keep up the temperature. When complete adhesion has taken place, the twisted strip of skin may be cut through, or a little slip may be cut out of it, so that the surface may be uniformly smooth. Either at the first operation or subsequently a new columna (the front part of the septum) is usually formed from the skin of the upper lip. When only a part of the nose, as one side only, or the septum, requires to be restored, modifications of the above operation are required, and the skin, instead of being taken from the forehead, is taken from the cheek or the upper lip. This operation is called the *Indian Method*, having been introduced from the East and first successfully performed in Europe by Carpie in 1814. It has almost entirely superseded the *Talercotian Operation*, first performed by Tagliacozzi or Taliacotius (1546-99), professor of Anatomy and Surgery at Bologna, and described in his famous work *De Curtorum Chirurgia per Insitionem* (1597). He took the skin for the new nose from the arm of his patient; and there is no reason why the operation which he describes, although inferior in many respects to that at present adopted, should not be successful. The difficulty of keeping the arm sufficiently long in apposition with the face (a period of about twenty days) is the chief objection to his method. The shape of the nose is also changeable at will by injection under the skin of hard paraffin in a melted state, by insertion of a slip of cartilage taken from one of the ribs, and other methods.

Rhizocarps. See WATER-FERNS.

Rhizome, or ROOT-STOCK, is a creeping stem, which may grow just beneath the surface of the

soil or burrow deeply into it. A rhizome may be distinguished from a root, (1) by bearing terminal and other buds, although some roots, such as those of Elm, Poplar, Plum, &c. possess adventitious buds, which send up aerial shoots, often called suckers by gardeners, who detest them, unless they are required to increase the stock; (2) by non-green scale leaves, which are usually very small; (3) by green aerial leaves, or the scars or even the dead remains of such leaves, which sometimes entirely cover the rhizome, as in Wood Rush; green leaves, however, are often on short or long aerial shoots growing from the rhizome, which may also produce the flowers as in Solomon's Seal; such aerial summer shoots leave their dead remains, or their scars on the rhizome; (4) by adventitious roots, which are given off here and there, scantily, as in Bracken, or in great abundance as in Male Fern; but in a few cases roots are absent, the rhizome itself taking the function of a root, as in the Coal-foot Orchid; (5) microscopically, by the absence of the exarch primary wood of roots, as revealed by a transverse section (see ROOT and STEM). In fact, what the grower calls root is really a combination of root and stem, the lower part deep in the ground being root, and the upper leaf-bearing part, and for several inches down, being stem. The two parts differ not only microscopically, but also in the fact that the valuable sugar is stored chiefly in the stem. Hence those who raise new varieties of these plants endeavour to increase the stem portion by selection and other devices.

The functions of rhizomes, of great importance to many plants, are (1) to preminate the plant over the unfavourable season; (2) to increase and spread the plant by vegetative propagation; (3) to form dense extensive associations of one kind of plant, where the environment is suitable, as in reeds of a swamp, or to produce more or less isolated clumps of plants, as in many tufted sedges, grasses, &c.; (4) to bind loose soil such as sand or mud, and thus provide for the plant's future; (5) to ensure the succession of the plant in localities where seasons or other ecological factors favourable to seed production occur only now and again. It would appear that the vegetative and sex reproductive methods are reciprocal. Thus the common Lesser Celandine growing on a well-drained sunny bank produces a fair abundance of seed, and but few reproductive tubers, whereas in a damp, shady position tubers are abundant and seeds rare.

In autumn the aerial portions of the plant may wither, but the rhizome continues to live either in a condition of latent life or in a state of slow growth preparing its buds to push above ground early in spring. Rhizomes are usually well stored with reserve food, such as starch or sugar and protein, for use of the growing parts, and it is from this stored energy that slow winter growth below ground, and rapid spring growth above are provided for. The stored food is therefore more abundant in autumn than at the maximum of spring growth.

Rhizomes commonly burrow in a direction more or less horizontal with the surface of the soil, in which case the upper and lower sides may differ in form, so that a typical rhizome may be considered as a dorsiventral organ of the plant: it is also endowed with polarity. When, however, rhizomes grow more or less vertically, as in many ferns, &c., they have a radial symmetry similar to ordinary stems. When rhizomes branch, as they frequently do, these, like the main axis, also produce apical and lateral buds, which sooner or later grow into aerial shoots. Any portion of a rhizome, or its branch, bearing an evident, or a latent and therefore inconspicuous bud, may reproduce the parent plant; and such portions of rhizomes can be cut off and set in the soil for raising new plants of

exactly the same kind. This method is familiar to gardeners. Indeed, in the case of many obnoxious weeds, as well as numerous desirable garden plants like *Tritonia*, *Epilobium*, *Mint*, &c., this plan for rapid increase is but too well known. Hence arises the difficulty in keeping down, or within the confines of a border, weeds like Couch-grass, Colts-foot, Bracken, Corn-thistle, Bishop-weed, Bind-weed, Stinging-nettle, Horse-tail, Butter-bir, Creeping-butternut, &c., and the garden plants mentioned above, along with hundreds of other examples. Almost every scrap of the rhizome of such plants broken off and left in the ground speedily produces another plant. Dandelion, Plantain, and Dock are pests of a similar class, the vitality of whose more or less vertical rhizomes on lawns is well known. The power of reproduction exhibited by such weeds is due to the nutrient substances stored in the rhizome, which feed the incipient and latent buds and root origins. From the practical consideration of many farm and garden crops weeds of the class mentioned can be attacked only in winter, which is just the season when their rhizomes contain the largest supply of stored food, and are therefore more likely to reproduce copiously from broken bits than would be the case at the flowering period, when the rhizomes would be partially depleted of food.

In many plants, as in some common ferns, the rhizome dies gradually behind as the apex grows in front. When rhizomes of this class produce lateral branches, these become liberated in time by the advancing decay of the main axis, and spread the plant to a small extent in all directions. This is illustrated by the great clumps of Male Fern observable in old woods and gardens. In this case, however, the young plants arise too close to the original rhizome; and as each produces a vast quantity of wiry roots which push the soil from the older central rhizomes, these consequently tend to become starved. In this way a vital barrier terminates the existence of that which is theoretically immortal.

Many rhizomes, particularly of Monocotyledons, exhibit false or sympodial branching (see BRANCH), as beautifully shown in Solomon's Seal. Others, more rarely, have the axis on the monopodial plan, as the Primrose. The most simple types of rhizome being elongated and narrowly cylindrical, correspond more or less closely with the usual aerial stems of plants. Sometimes the elongating energy is suppressed, and a very dwarf stem results, as in Primrose and Cyclamen. In the last, while vertical extension is almost completely suppressed, a lateral growth produces the tuber like axis. In other cases a similar mode of growth occurring here and there along a narrow elongated axis, the vertical suppression usually including several internodes, results in a tuber such as Potato and Jerusalem Artichoke. When leaves or scale-leaves arise from the base of a tuber and enclose it within their scarious bases, a corm results, as in Crocus, Gladiolus, &c. If the energy of the axis is suppressed to a considerable extent laterally as well as vertically, and this dwarf, flattened stem or rhizome is surrounded and partially enclosed by fleshy scale-leaves, or the fleshy bases of former aerial scale-leaves, or a combination of both kinds, a bulb results, as respectively in Tulip, Daffodil, and Hyacinth. If the individual fleshy leaves are very wide, and encircle the dwarf stem so that when a thin transverse slice is cut they fall away in rings, as in the kinds just mentioned, to which may be added the familiar Onion, then the bulb is said to be tunicated or concentric. On the other hand, if the fleshy leaves are comparatively narrow and cover the axis by overlapping one another like the tiles on a roof, then a scaly or imbricated bulb results, as in Lily. Transitional forms occur between these common definite examples. Corms and bulbs, then,

are in reality dwarf rhizomes with large, modified, subterranean buds which, indeed, often form the bulk of the plant in the resting stage. The fleshy leaves serve as storage organs for reserve food instead of the stem as in ordinary rhizomes. Tubers are akin to rhizomes on the one hand, and to corms or 'solid bulbs' on the other hand, while the latter approach the more highly developed scaly and tunicated bulbs.

From the fact that certain kinds of fungi are frequently found in intimate contact or even within the tissues of some tubers, corms, and bulbs, the idea has been suggested by various botanists that tuberisation is due to the stimulating effect of such fungi, which accelerate cell-increase and the accumulation of reserve food substances. Should the fungus-infection hypothesis of tuberisation be ultimately confirmed, then tubers, corms, and bulbs will have to be classified along with galls. The tuberisation of rhizomes generally is favoured by darkness and moderate dryness of soil. Hence the 'earthing up' of potatoes.

The rhizomes of *Polygala polygama*, and a few other plants are very remarkable in that they produce cleistogamous flowers (see CLEISTOGAMY) underground, which pollinate and ripen seed entirely below the surface.

Dry periods present great difficulties to plants (see ECOLOGY). It is interesting to compare the similar effect on bulbous plants of the diverse climates of the open plains of South Africa and our native deciduous woods. In South Africa the long dry summer establishes a condition of physical drought for the bulbous plants which are then in a dormant or semi-dormant condition below the soil-surface. When the damp season returns the plants are stimulated to activity, and the barren ground becomes gay with flowers. In our woods the trees absorb all available water from the upper layer of soil in early summer, so that bulbous plants like Daffodil, Wood Hyacinth, and Garlic are starved of water, and their aerial parts complete their functions and die down; the leaves of the trees, moreover, render the environment untenable by shade. In winter the soil is too cold, although rarely frozen to any depth, because the trees check the radiation of heat from the earth through the light humus loam. In early spring the sun warms the light, damp soil through the leafless trees, which also screen off cold winds; the absorptive power of the tree roots is almost nil, and the bulbous and rhizomatous plants have their one chance of the year. Their leaves and flowers then make the woods gay with colour until the roots and leaves of their giant neighbours once more initiate the period of repose.

The underground parts of plants discussed herein are, on account of their storing habits, often of great use to man.

See BULB, CORM, TUBER, ROOT, STEM; T. Irmisch, *Zur Morphologie der monokotylenischen Knollen- und Zwiebelgewächse*, and other works of this author; Kerner and Oliver, *Natural History of Plants*; papers by Maize (1900), Rumbach (1900-1902), Lidfors (1903), Massart (1903), Fors (1903), Raunkiaer (1904), Robertson (1906), Sperlich (1906), François (1908), Blodgett (1910); and all the large text-books on general botany, horticulture, &c.

Rhizopoda (Gr. *rhizon*, 'a root,' and *podes*, 'feet'), a division of the Protozoa, in which the amoeboid phase of cell-life is predominant, the living matter flowing out in changeful processes or 'pseudopodia.' Some authorities include within the term (*a*) the Lobosa, such as *Amoeba* (q.v.), (*b*) the Filosa, such as *Euglypha* and *Gromia*, (*c*) the Foraminifera (q.v.), (*d*) the Heliozoa or Sun-animalcules, and (*e*) the Radiolaria (q.v.); others only (*a*), (*b*), and (*c*); others only (*a*) and (*b*).

Rhode Island, smallest of the United States, and one of the original thirteen of the Union. The

state takes its name from the *island* of Rhode Island, or Aquidneck, in Narragansett Bay (a beautiful islet 15 miles long by 3 wide). Of the *state* the extreme length from north to south is 47½ miles, and its average breadth 35 miles; land area, 1053 sq. m. Rhode Island has thus a land surface only about $\frac{1}{10}$ th as great as that of Texas, the largest state; but, while it ranks only thirty-eighth among the forty-eight states in order of population, in density of population (566 per sq. m.) it holds the first place. Its name is referred by some to a supposed resemblance of the island of Rhode Island to Rhodes in the Mediterranean, while by others it is considered to be a corruption of *Roodt Eylandt* ('Red Island'), a name bestowed upon this island by the early Dutch.

There are no mountains in the state, but the surface is considerably diversified. The northern and eastern sections are hilly, and the land slopes toward a level region in the south. The most important elevations are Woonsocket Hill, Mount Hope, Diamond Hill, and Hopkins Hill. The coast along the Atlantic Ocean measures about 45 miles, but Narragansett Bay, which penetrates inland some 30 miles, affords with its various inlets about 350 miles of shore washed by tide-water. The southern coast west of Point Judith is low and sandy, with numerous fine beaches, and many marshes and ponds of salt water. To the west the shores are formed by high rocky cliffs interspersed with beaches of sand. Newport, Narragansett Pier, and Watch Hill, on the ocean coast, are among the most famous seaside resorts of the country; and Block Island, about 10 miles SW. of Point Judith, is also a favourite watering-place.

The western part of the state is marked geologically by the Achean formation which is characteristic of much of New England, but an extensive coal-bearing area of the Carboniferous period stretches under the bay across the eastern part of the state into Massachusetts. It is the most eastern bed of anthracite in the United States, but thus far the coal which has been mined has been of inferior quality. There are deposits of iron ore, and excellent limestones and granite. Traces of the terminal moraine of the glacial period are visible in the state, and in many places the soil is stony or rocky, though in some localities it is moderately fertile. Agriculture, however, except in the way of market-gardening, is by no means a leading occupation.

Rhode Island enjoys a maritime climate, milder and more equable than that of other portions of New England. The rivers of the state are of little importance for navigation, but are of great value in furnishing water-power, and have played a prominent part in developing the industries of the state. The principal rivers are the Seekonk, navigable to Pawtucket, the Woonasquettucket, the Pawtuxet, and the Pawcatuck.

Newport has one of the finest harbours in the world, and the bay affords an extensive area of safe anchorage, with excellent ports at Bristol, Warren, and Providence. Formerly these places enjoyed a large foreign commerce, which finally disappeared with the war of 1812, and, though a considerable coasting trade is still carried on, commerce from that time ceased to be a prominent industry. It was replaced by manufacturing, which has ever since been the characteristic occupation of the people. The cotton manufacturing industry of the United States had its birth in Rhode Island, and dates from 1790. Cotton manufacturing, with dyeing, bleaching, and calico-printing, is followed in importance by the manufacture of woollen and iron goods, jewellery, rubber and leather goods. The principal towns

are Providence, the capital (237,595); Pawtucket (64,248); Woonsocket (43,496); Newport (30,255), till 1900 one of the two capitals of the state; and Central Falls (24,174).—The Northmen are supposed to have visited Rhode Island in the 10th century; and the 'Old Stone Mill' at Newport (q.v.) has been claimed as their work. The first permanent settlement was made at Providence by Roger Williams (q.v.) in 1636. Rhode Island was the last (1790) of the original thirteen states to ratify the constitution. In the war of the revolution, in that of 1812, and in the civil war of 1861-65 she took an active part. Pop. (1730) 17,935; (1830) 97,199; (1880) 276,531; (1900) 428,556; (1920) 604,397.

Rhodes, an island of the Mediterranean belonging to Italy, once a famous Greek state, lies 12 miles distant off the south-west coast of Asia Minor. It is 49 miles long and 21 broad, and is traversed by a chain of mountains reaching a height of 4070 feet. The soil is on the whole fertile, but the land has never been fully developed; fruit and vegetables are exported. Pop. 36,500.

The first historic inhabitants of ancient *Rhodos* were Dorian Greeks from Argos. Situated between the three ancient continents, the Rhodians early became very prosperous and affluent, and planted numerous colonies not only on the neighbouring shores, but also on the coasts of Italy, Sicily, and Spain. The island submitted to the Persians in 490 B.C., but the Athenian supremacy soon took the place of the Persian. The intestine struggle between the oligarchical party (backed by Sparta) and the democratic (supported by Athens) went on until Rhodes submitted to Alexander of Macedon in 332 B.C.; but after his death the Rhodians revolted again. Then began their most prosperous period; they became the first naval power in the *Ægean*, their ships being well built, and always splendidly manned and manoeuvred. As allies of the Romans, they opposed the Macedonians and Antiochus of Syria; and they won great glory by beating off Mithridates in 88 B.C. The Rhodians finally sided with Caesar; but, venturing to oppose Cassius, the city was plundered by him (43 B.C.), and her ships all carried off or destroyed. This struck a fatal blow at her naval power. Under Vespasian Rhodes was made a Roman province; and in the 7th century it was captured by the Saracens and held for six years. As part of the Byzantine empire again, it was, in the Crusades, a convenient stopping-place for the Christian fleets. In the 13th century it was held by the Venetians and by the Genoese, who were turned out by the Byzantines. In 1309, after a three years' siege, the city fell into the hands of the Knights Hospitallers (q.v.) of St John, who made it their headquarters. The Turks besieged them there in 1480, and again in 1522-23; on both occasions there was terrible fighting, the Turkish losses being 25,000 and 90,000 to 100,000 men during the two sieges respectively. The Knights, who under their grand-master D'Aubusson (q.v.) beat off the Turks in the terrible siege of 1480, were compelled, in spite of their valour and the skill of their grand-master, De Lisle Adam, to capitulate on honourable terms (after the Turks had lost some 100,000 men) in 1523. The island remained Turkish up to the Libyan war in 1912, when it was pledged with the Dodecanese (q.v.) to Italy, which has held it ever since. The Italian occupation is unpopular with the inhabitants, who are mainly Greeks.

The city stood at the northern extremity of the island, on the slopes of a natural amphitheatre, and was built (404 B.C.) on a regular plan and strongly fortified. At the entrance of one of its two excellent harbours stood the gigantic statue of Helios, the Colossus (q.v.). Besides this statue,

one of the seven wonders of the ancient world, 3000 others, of which 100 were colossal, adorned the city, even in the 1st century A.D. The city suffered severely from earthquakes in 227 B.C. (when the Colossus was thrown down), 157 A.D., 515, 1364, 1481, 1851, 1856, and 1863. The city was famous for the number and excellence of its paintings, sculptures, and statues, the latter including the Laocoon (q.v.) and the Farnese Bull. Parrhasius and Protagenes were amongst its painters, and its sculptors, poets, rhetoricians, and athletes were well known throughout the Greek world. The first meridian of ancient geographers passed through Rhodes. The existing city dates for the most part from the period of the Knights; notable buildings being the church of St John, the Knight's hospital, and the grand-master's palace. The city walls still stand. Rhodes is the seat of a Greek archbishop. Pop. 10,000. 'Rhodian Law' was a code compiled by the ancient Rhodians while they held the sovereignty of the sea. See Belabre, *Rhodes of the Knights* (1909); Skevos Zervos, *Rhodes, Capitale du Dodécanèse* (Paris, 1920); and M. D. Volonakis, *The Island of Rhodes and her Eleven Sisters* (1922).

Rhodes, the Rt. Hon. CECIL JOHN, statesman, was born 5th July 1853, the fifth son of the vicar of Bishop-Stortford in Hertfordshire, and after attending the local grammar-school was sent for his health to Natal, where his brother was a planter. He subsequently went to the Kimberley diamond diggings; there he soon became conspicuous and amassed a fortune. He came back to England and entered at Oriel College, Oxford, and though his residence was cut short by ill-health he ultimately took his degree. He entered the Cape House of Assembly as member for Barkly. In 1884 General Gordon asked him to go with him to Khartum as secretary; but Rhodes had just taken office in the Cape ministry. He sent £10,000 to Mr Parnell to forward the cause of Irish Home Rule. In 1890-94 he was prime-minister of Cape Colony; but even before this he had become the ruling spirit in extensions of British territory, as in securing the charter for the British South Africa Company (see MATABELELAND). He it was mainly who brought it about that Bechuanaland remained a British possession, instead of falling to the Boers. And Rhodesia (q.v.) has not unnaturally superseded Zambesia as the name of a vast area now British, north and south of the Zambezi, which he had done much to develop. For the Jameson raid into the Transvaal, which he was believed to have prompted, see JAMESON (L. S.). From 1898 on he strenuously promoted an African Continental telegraph and a 'Cape to Cairo' railway. He was in Kimberley during the siege by the Boers. He died 26th March 1902, and was buried in the Matopos Hills. By his will he founded, out of his vast fortune, 60 scholarships for colonials, tenable at Oxford for three years, besides foundations of the same kind for Americans and Germans. In 1916, the German scholarships were by Act of Parliament distributed among the dominions. There are Lives by Sir Lewis Michell (1910), Sir T. E. Fuller (1910), P. Jourdan (1910), and Basil Williams (1921), and a collection of his speeches (1890); see also *The Rhodes Scholarships*, by S. R. Purkin (1913), and the article on RHODESIA.

Rhodesia, named in 1895 after Cecil Rhodes (q.v.), is a vast plateau bounded by the Transvaal, Bechuanaland, Angola, Belgian Congo, Tanganyika Territory, Nyasaland, and Portuguese East Africa. It is divided by the river Zambezi (q.v.) into two unequal divisions. While the interests of Southern Rhodesia are similar to those of

South Africa, Northern Rhodesia is geographically, climatically, and in its vegetation part of Central Africa.

Southern Rhodesia is much the more developed of the two regions. Consisting of Mashonaland (q.v.) and Matabeleland (q.v.), it has an area of some 150,000 sq. m., with a white population of 34,000 (90 per cent. English-speaking) and a native population estimated at about 800,000. Almost half the country is situated between 3000 and 4000 feet above sea-level, and about a fifth between 4000 and 5000 feet. The mean annual temperature ranges from 75° F. to 70° in the lower regions, and from 70° F. to 65° in the higher. The mean annual rainfall is 28 inches. The country is healthy, malaria and blackwater fever not being prevalent. The rivers are not navigable, except for native craft. Guinea-fowl, partridge, sable and roan antelopes, wildebeest, and zebra are plentiful. The country is wide and undulating, with broken ranges of hills covered with small timber, and is very suitable for agriculture and ranching. Since 1923 (see *History*) the government has been vested in a governor, an executive council, and a legislature. The seat of government is Salisbury (white pop. 6500), the capital of Mashonaland. There is a High Court with civil and criminal jurisdiction, also magistrates' courts and municipalities at Salisbury and Bulawayo (chief town of Matabeleland, white pop. 7400). There are great gold-mining possibilities, but the modern mines have been developed mostly on the site of ancient workings (see MINING). The total output of gold from 1890 to 1924 was worth 604 millions of pounds. Other minerals are coal, chrome ore, asbestos, and copper. Maize is the staple crop, but tobacco, and fruit-trees, especially oranges and lemons, are very important, as is also cattle-rearing. The natives are taking rapidly to agriculture, and areas amounting to a quarter of the whole country are reserved for them. The imports are chiefly machinery and manufactured goods: of exports, one-half is accounted for by gold. The trade is principally with Great Britain. In 1906 Alfred Beit bequeathed £200,000 for educational, public, and charitable purposes. Rhodesia sends annually three Rhodes scholars to Oxford.

Railways.—The total mileage of the Rhodesian railway system is 2468 miles, of which 1052 are situated in Southern Rhodesia. The system extends from Vryburg in the Union of South Africa through Bulawayo, across the Zambezi at the Victoria Falls to the Congo frontier, and from Bulawayo *via* Salisbury to the port of Beira in Portuguese East Africa. The bridging of the river Limpopo at Messina, bringing Rhodesia into direct communication with North Transvaal and Lourenço Marques, and the extension of the line from Salisbury across the Zambezi to Katue, have been much discussed.

Northern Rhodesia has an area of some 300,000 sq. m., with a white population of 3700 and a native population estimated at about 1,000,000. The region west of the railway is known as Barotseland (q.v.). Except for the railway strip Northern Rhodesia is really a native reserve, and native rights are strictly safeguarded; it is practically all over 4000 feet above sea-level, and there are numerous belts of tsetse fly. Big game is abundant, elephants, hippopotami, lions, hyenas, crocodiles, &c. Much of the country is dense bush, and in the north-east there are vast swamps with a purely tropical climate. Since 1924 it has been a British protectorate (see *History*) with the capital at Livingstone. The country is very undeveloped, though there is a certain amount of sheep-farming a trade in ivory, and in the region of the railway there are lead mines.

History.—For 19th-century history, see BAROTSELAND, MASHONALAND, MATABELELAND. In this period Rhodesia was almost a sealed book to all but the most adventurous of sportsmen, and missionaries like Moffat and Livingstone. From 1889 to 1923 Rhodesia was under the administration of the British South Africa Company, founded by Cecil Rhodes to keep the hinterland of South Africa British. The company was incorporated by Royal Charter, and on the whole the administration was successful. Slavery was abolished, the sale of spirits to the natives prohibited, railways were built (the Zambezi was bridged in 1904, and the Congo reached in 1909), and trade, agriculture, and mining encouraged. The Matabele Wars (1893 and 1896), a terrible epidemic of rinderpest, the Jameson Raid (see JAMESON, SIR L. S.), and the Boer War (1899-1901) all seriously retarded the development of the country. In 1898 the Secretary of State nominated a resident commissioner in Southern Rhodesia; other orders-in-council appointed a Secretary for Native Affairs besides two chief Native Commissioners, and other officials and a legislative council. In 1906 the chartered company might have paid a dividend (for the first time), but chose instead to divide the balance-sheet into two parts, one to be devoted to administrative and the other to commercial purposes. Meanwhile among the Rhodesian settlers a feeling of opposition to the company was steadily growing. The company had secured mining and other monopolies, and had responsibilities to its shareholders; a certain amount of land was locked-up by absentee landlords, and finally the country had no real control over its own finance, being unable to issue loans for public works. The agitation for self-government was shelved during the Great War, when 40 per cent. of the white adult population went on active service (a larger percentage than any other part of the empire), but in 1922 a referendum was taken in Southern Rhodesia, the alternatives being responsible independent government, or absorption, under admittedly liberal terms, into the Union of South Africa as a fifth province (strongly advocated by General Smuts, then Premier of the Union). Out of an electorate of over 18,000, 5989 voted for the Union and 8774 for responsible government, and in 1923 Southern Rhodesia emerged from the tutelage of the company. (It should be remembered that amalgamation with the south would imply a loss in individuality, as the Dutch element in Rhodesia is exceedingly weak.) The company retained the mineral rights, the control of the railways (though this will doubtless be modified), and was considered entitled to payment of its administrative deficits—estimated at 5 millions sterling, to be defrayed by the sale of malienated crown lands. In 1924 Northern Rhodesia was taken over from the company and made a British protectorate.

Rhodesia has a great future before it, but much capital is required for its development, with irrigation schemes, land settlement, and railway construction.

Brown's annual *Guide to South and East Africa*; the *Colonial Office List*; and the official *Yearbook*.

Rhodium (sym. Rh; atom. number 45; at. wt. 102.9; sp. gr. 12.1) is a metal of the platinum group. It is a white, very hard metal, resembling aluminium rather than silver. It fuses less easily than platinum. It is ductile and malleable when

pure and after fusion, and insoluble in all acids; but when alloyed in small quantity with platinum, copper, bismuth, and lead it dissolves with them in *aqua regia*. It usually forms about one-half per cent. of the ore of platinum, from which it is extracted by a somewhat complicated process. Three oxides, two sulphides, and a chloride of rhodium have been obtained and examined by chemists. The chloride unites with several soluble chlorides to form crystallisable double salts, which are of a rose colour (whence the name rhodium, from the Gr. *rhodon*, 'a rose'). The metal was discovered in 1803 by Wollaston.

Rhododendron (Gr., 'rose-tree'), a genus of trees and shrubs of the family Ericaceae, having ten stamens, a very small calyx, a bell-shaped or somewhat funnel-shaped corolla, and a capsule splitting up through the dissepiments. The buds are scaly and conical. The species are numerous; they have evergreen leaves, and many of them are of great beauty both in foliage and in flowers. A few species are natives of continental Europe and of Siberia; but the greater number belong to the temperate parts of North America, and to the mountains of India, Tibet, and China. *R. maximum*, so designated when the far larger Indian species were unknown, is common in Britain as an ornamental shrub. It is a large shrub or small tree, which forms impenetrable thickets on many parts of the Alleghany Mountains, and has a magnificent appearance when in flower. The leaves are large, oblong, acute, stalked, leathery, dark green and shining above, rusty brown beneath. The flowers are large, in umbellate corymbs, varying in colour from pale carmine to lilac. This species is quite hardy in Britain; as is also *R. ponticum*, a yellow flowered species, with narrower and more pointed leaves, which are of the same colour on both sides. It was known until recently from southern Portugal and the Caucasus, the distance being to some extent bridged over by interglacial finds of this plant near Lugano, and Hottling in Tirol. But habitats have been found in Bulgaria, in Northern Volhynia, and in Poland near the Vistula and the river San. *R. ponticum* is the plant responsible for the mishap to Xenophon's troops (*Anabasis* iv. 8). *R. cataractense*, a native of the southern parts of the Alleghanies, with large purple flowers; *R. caucasicum*, whose name indicates its origin; and *R. arboreum*, a

Rhododendron arboreum.

native of Nepal, with very dense heads of large scarlet flowers, and leaves 4-6 inches long, attaining in its native country a height of 30 or 40 feet, are also fine species, and well known. Most of the extremely numerous varieties now common in our gardens and shrubberies have been produced from

them by hybridising or otherwise. Many splendid species of rhododendron were discovered in the Himalayas, the Khasia Hills, and other mountainous parts of India, by Hooker and others; and many of them have been introduced into cultivation in Europe. *R. Falconeri* is described as in foliage the most superb of all, the leaves being 18 or 19 inches long. It is a tree 30-50 feet high, with leaves only at the extremities of the branches. It grows in eastern Nepal at an altitude of 10,000 feet. *R. grande* has flowers $4\frac{1}{2}$ inches long, and equally broad, clustered, and very beautiful. *R. Muddeni*, *R. Griffithianum*, *R. Edgeworthii*, and others have white flowers. *R. Dalhousiae* is remarkable as an epiphyte, growing on magnolias, laurels, and oaks. It is a slender shrub, bearing from three to six white lemon-scented bells, $4\frac{1}{2}$ inches long, at the end of each branch. *R. Nuttallii* has fragrant white flowers, said to be larger than those of any other rhododendron. All these belong to the Himalayas. In more southern latitudes, as on the Neillgherry Hills and on the mountains of Ceylon, *R. campanulatum* prevails, a timber tree 50 to 70 feet high, every branch covered with a blaze of crimson flowers. *R. Keaysii* and *R. cinnabarinum*, natives of the north of India, have flowers with nearly tubular corolla. *R. ferrugineum* and *R. hirsutum* are small species, shrubs from 1 to 3 feet in height, natives of the Alps, and among the finest ornaments of alpine scenery. They are called *Alpenrose* (Alpine Rose) by the Germans. They have small carmine-coloured flowers in umbellate clusters. The mountain-slopes glow with their blossoms in July and August. The former grows only on the siliceous, the latter on a calcareous, substratum. In districts where both kinds of soil occur the two species have formed a constant hybrid, *R. intermedium*. The flora of the Himalayas contains a number of similar small species. *R. Anthopogon* and *R. setosum*, dwarf shrubs with strongly-scented leaves, clothe the mountains in eastern Nepal, at an elevation of 12,000 feet and upwards, with a green mantle, brilliant with flowers in summer. *R. nivale* is the most alpine of woody plants, spreading its small woody branches close to the ground at an elevation of 17,000 feet in Sikkim. *R. lapponicum*, a procumbent shrub, with small flowers, grows as far north as human settlements have reached in Europe, Asia, and America. Rhododendron is in the East as polymorphous a genus as *Rubus* in the West. The Tibetan region alone boasts 130 species in its lofty ranges, with a large number most likely still awaiting discovery. *Azalea* (q.v.), formerly regarded as a genus, is now included in Rhododendrum. See J. G. Millais, *Rhododendrons* (1917 24).

Rhodope, the ancient name of a mountain-chain (7474 feet) extending along the borders of Macedonia and Thrace. The Turks call it *Dospud Yailasi*, the Bulgarians *Despoto Daghi*, both titles having reference to the numerous (Greek) monasteries that stud its sides. Of these the most famous is the vast fortress monastery of Rilo, in the north-west of the range, standing on its southern side in the midst of magnificent pine forests. Rilo has long been the focus of the Bulgarian church and of Bulgarian nationality. Founded in the 10th century, the monastery was built mainly in the 14th century, being destroyed in 1833, and reconstructed on the old plans.

Rhondda, an urban district (1894) and two-member parliamentary borough (pop. 102,729) of Glamorganshire.—The Rhondda Valley, named from a tributary of the Taff, is a great centre of coal-mining and is nevertheless still famous for its fine scenery.

Rhone (Lat. *Rhodanus*), the only important

French river which falls into the Mediterranean, takes its rise in the Swiss Alps, on the western side of Mount St Gothard, at an altitude of 5752 feet, and not far from the sources of the Rhine. Its entire length, from its source to its mouth in the Gulf of Lions, is 504 miles, and the area of its river-basin 38,170 sq. m. It first runs in a south-westerly direction through the canton of Valais, along a narrow valley between the Bernese and the Pennine divisions of the Alps, until near Martigny it takes a sudden turn to the north and pours its waters into the Lake of Geneva (q.v.). It issues from the lake at its southern extremity, proceeding west, and then forces a passage through the Jura. The municipality of Geneva has taken advantage of the strong and steady current of the river where, passing through the city, it is divided by an island into two arms, to utilise it for industrial purposes. Formerly the river used to disappear for some distance near Fort l'Ecluse into the subterranean channel *La Perte du Rhône*; but the vault or covering of the gorge into which it plunged has now been blasted away. At St Genis the Rhone turns back suddenly to the north-west, and then once more flows westward through a more level country as far as Lyons, where it is joined by its largest tributary, the Saône (283 miles long), from the north. From Lyons it follows a southern direction past Vienne, Valence, Montélimart, Avignon, and Arles, where begins its delta, embraced between two main arms, the Greater and the Lesser Rhone. Its most important affluents are, on the right, the Ain, Saône, Ardèche, and Gard; on the left, the Aise, Isère, Drôme, and Durance. From Lyons southward the Rhone is easily navigable for good-sized vessels; but the up-navigation, owing to the rapidity of the current and the sudden shifting of sandbanks, is attended with considerable difficulty, and is at times almost impracticable. A great scheme for utilising the whole course of the river through France for navigation, irrigation, and electric power was passed by the legislature in 1921; but for the uppermost part the maintenance of the level of the Lake of Geneva remained a matter for negotiation with Switzerland. On account of these and other difficulties, especially near the mouths of the river, communication with the Mediterranean is in great part dependent upon canals. Canals likewise connect the Rhone with the Rhine by the Saône, with the Seine, the Loire, and the Garonne.

Rhône, a department of France, part of the former Lyonnais, has an area of 1077 sq. m. and a pop. (1921) of 956,566 (741,470 in 1881). It lies almost wholly in the basin of the Rhone and the Saône, its eastern boundary being formed by these rivers. The surface is almost entirely hilly, being broken up in all directions by low spurs of the Cevennes. Corn, potatoes, wine, and fruits are the principal products. The department is industrially one of the most important in France; all the branches are carried on at Lyons (q.v.), its capital. The arrondissements are Lyons and Villefranche. See also *BOUCHES-DU-RHÔNE*.

Rhubarb (Low Lat. *rheubarbarum*, from Gr. *rhêion barbaron*, literally 'barbarian Rhenn'; 'rhêion' is an adjective from *Rhe*, 'the plant found near the river Rhe'—i.e. the Volga; the botanical name being simply *Rheum*), a genus of plants of the Polygonaceæ, closely allied to *Rumex* (dock and sorrel), from which it differs in having nine stamens, three shield-like stigmas, and a three-winged acheneum. The species, about twenty, are large herbaceous plants, natives of the central regions of Asia, with strong, branching, almost fleshy roots; erect, thick, branching stems, sometimes 6 or 8 feet high; the stems and branches

whilst in the bud covered with large membranous sheaths. The leaves are large, stalked, entire or lobed; the flowers are small, whitish or red, generally very numerous, in large loose panicles of many-flowered clusters. The roots are medicinal. The leaf-stalks contain an agreeable mixture of citric and malic acids. The kinds cultivated for tarts and the like, *R. undulatum*, *R. Rhaponticum*, and *R. hybridum*, with endless varieties produced by the art of the gardener, all have broad, heart-shaped leaves, and the leaf-stalks flattened and grooved on the upper side. The leaf-stalks are often of a reddish colour, which in some of the finest varieties pervades the whole flesh.

Rhubarb (*Rheum officinale*).

Rhubarb is forced in winter and early spring by being placed in pots within houses, or by having pots inverted over it, and dung and straw heaped around; and forced rhubarb is more tender and delicate than that which grows in open air. The stalks when blanched are much less harsh in taste and require less sugar. The well-known medicinal *R. officinale* differs considerably in appearance from the kinds preferred in kitchen gardens; the petioles are nearly round, and the under side of the leaf is covered with small, erect hairs.

Chemically, rhubarb consists of mucilage, oxalate of lime, an albuminoid containing nitrogen and sulphur, crystalline resins, tannin, gallic acid, sugar, chrysophane (decomposable into chrysophanic acid and glucose), rheotannic acid, and emodin.

Rhubarb may be briefly described as a cathartic, an astringent, and a tonic. As a cathartic it chiefly operates by increasing the muscular action of the intestines; and when the cathartic action is over there is generally more or less constipation. Rhubarb is one of the best aperients for general use in infancy, in consequence of the certainty of its action, and of its tonic and astringent properties, which are of much importance in the treatment of many infantile diseases attended with imperfect digestion and irritation of the intestinal canal. In adults it is serviceable in chronic diarrhoea and dysentery, when it is expedient to clean out the bowels. It is also a useful aperient in convalescence from exhausting disease, as being free from the risk of overacting; and, for the same reason, it is a useful medicine for persons who are constitutionally liable to over-purgation from trivial causes.

Rhuddlan, a town of Flintshire, North Wales, on the Clywd, 3 miles SSE. of Rhyl. Its ruined castle, dating from 1015, and dismantled after its capture by the Roundheads in 1646, was the scene

of the betrayal of Richard II. by Percy (1399): at the marsh of Morfa Rhuddlan, across the river, Olla defeated Cadwallo (795). With Flint, &c., Rhuddlan till 1918 returned a member to parliament.

Rhus. See SUMACH.

Rhyl, a watering-place of Flintshire, North Wales, at the mouth of the Clywd, 30 miles NW. of Chester. A mere fishing-village so late as 1830, it has fine sands, and it commands good views of the Snowdonian mountains. Pop. 13,400.

Rhyme, or RIME (not from O. E. *rim*, 'number,' but O. Fr. *rime*, from Gr. *rhythmos*), is the most prominent mark of versification in all the modern Germanic and Romance tongues—viz. the recurrence of similar sounds at certain intervals. As there may be various degrees and kinds of resemblance between two syllables, there are different kinds of rhyme. When words begin with the same consonant we have *Alliteration* (q.v.), which was the prevalent form of rime in the earlier Teutonic poetry, as in Old English. In Spanish and Portuguese we find employed a peculiar kind of rime called *Assonance*, consisting in the coincidence of the vowels of the corresponding syllables without regard to the consonants; this accords well with the character of these languages, which abound in full-toned vowels, but is ineffective in English and other languages in which consonants predominate. In its more usual sense, however, rime denotes correspondence in the final syllables of words, and is chiefly used to mark the ends of the lines in poetry. Complete identity in all the parts of the syllables beginning with the same consonants constitutes what the French call *rich* rime, as in *modèle, fidèle; beauté, santé*. They designate as *poor* rimes most of such rimes as English verse allows—collocations of similar syllables beginning with different consonants, as *page* and *rage*, *nut* and *instruit*. Undoubtedly one of the delights of rime is expectance, but that of uniformity in variety, rather than of monotonous and absolute uniformity. Although such rimes are not only allowed but sought after in French, in English they are deservedly considered faulty, or rather as not true rimes at all. No one thinks of making *deplure* rime with *explore*. Rhiming syllables in English must agree in so far, and differ in so far: *the vowel and what follows it—if anything follow it—must be the same in both; the articulation before the vowel must be different*. Thus, *mark* rimes with *lack, bark, ark*, but not with *remark*. In the case of *mark* and *ark* the absence of any initial articulation in the latter of the two makes the necessary difference. As an example of rime where nothing follows the vowel we may take *be-fore*, which rimes with *fore-go*, or with *Gi*; but not with *to*. To make a perfect rime it is necessary, besides, that the syllables be both accented; *free* and *merrily* can hardly be said to rime. It is almost needless to remark that rime depends on the sound, and not on the spelling. *Plough* and *enough* do not make a rime, nor *case* and *decease*.

Such words as *roaring*, *de-ploring*, form *double* rimes; and *un-fortunate*, *im-portunate*, *triple* rimes. In double or triple rimes the first syllable must be accented, and the others ought to be unaccented, and to be completely identical. In the sacred Latin hymns of the middle ages the rimes are all double or triple. This was a necessity of the Latin language, in which the inflectional terminations are without accent, which throws the accent in most cases on the syllable next the last—*do-foram, vi-rorum; sup-plia, con-ricu*. Although rimes occur chiefly between the end-syllables of different lines,

they are not infrequently used within the same line, especially in popular poetry :

And then to see how ye neglectit,
How hauff'd, and enff'd, and disrespeckit,
And ice must-high came floating by.

When two successive lines rhyme they form a *couplet*; three form a *triplet*. Often the lines rhyme alternately or at greater intervals, forming groups of four (*quatrain*s) or more. A group of lines embracing all the varieties of metre and combinations of rhyme that occur in the piece forms a section called a *stave*, or *stanza*, often, but improperly, a *verse*. In the days of elaborate Acrostics (q.v.), verses constructed in shapes, and other conceits, it was the fashion to interlace rhymes in highly artificial systems; the chief complex arrangements now current in English are the various forms of the sonnet, and the Spenserian stanza. Tennyson accustomed the English ear to a quatrain in which, instead of alternate rhymes, the first line rhymes with the fourth, and the second with the third.

It is a mistake to suppose that rhyme is a mere ornament to versification. Besides being in itself a pleasing musical accord, it serves to mark the endings of the lines and other sections of the metre, and thus renders the rhythm more distinct and appreciable than the accents alone can do. So much is this the case that in French, in which the accents are but feeble, metre without rhyme is so undistinguishable from prose that blank verse has never obtained a footing, notwithstanding the war once waged by French scholars against rhimed versification. 'The advantages of rhyme,' says Grest, 'have been felt so strongly that no people have ever adopted an accentual rhythm without also adopting rhyme.' The Greek and Latin metres of the classic period, depending upon time or quantity, and not upon accent, were able to dispense with the accessory of rhyme; but, as has been well observed by Trench (*Introduction to Sacred Latin Poetry*), even 'the prosodic poetry of Greece and Rome was equally obliged to mark this (the division into sections or verses), though it did it in another way. Thus, had dactyls and spondee's been allowed to be promiscuously used throughout the hexameter line, no satisfying token would have reached the ear to indicate the close of the verse; and if the hearer had once missed the termination of the line it would have been almost impossible for him to recover it. But the fixed dactyl and spondee at the end of the line answer the same purpose of strongly marking the close as does the rhyme in the accentuated verse; and in other metres, in like manner, licences permitted in the beginning of the line are excluded at its close. The motives for this greater strictness being the same.' It is chiefly, perhaps, from failing to satisfy this necessary condition that modern unrhimed verse is found unsatisfactory, at least for popular poetry; and it may be doubted whether it is not owing to the classical prejudices of scholars that our common English blank verse got on maintained the hold it has.

The objection that rhyme was 'the invention of a barbarous age, to set off wretched matter and lame metre,' rests mainly on ignorance of its real history. It cannot be considered as the exclusive invention of any particular people or age. It is something human, and universal as poetry or music the result of the instinctive craving for well-marked recurrence and accord. The oldest poems of the Chinese, Indians, and Arabs are rhimed; so are those of the Irish and Welsh. In the few fragments of the earliest Latin poetry that are extant, in which the metre was of an accentual, not quantitative kind, there is a manifest tendency to ter-

minations of similar sound. This native tendency was overlaid for a time by the importation from Greece of the quantitative metres; yet even under the dominance of this exotic system rhimed verses were not altogether unknown; Ovid especially shows a liking for them :

Quot ecclim stellis, tot habet tna Roma puellas;

and in the decline of classicism they become more common. At last, when learning began to decay under the irruptions of the northern nations, and a knowledge of the quantity of words—a thing in a great measure arbitrary, and requiring to be learned—to be lost, the native and more natural property of accent gradually reappeared as the ruling principle of Latin rhythm, and along with it the tendency to rhyme. It was in this new vehicle that the early Christian poets sought to convey their new ideas and aspirations. The rhymes were at first often rude, and not sustained throughout, as if lighted upon by chance. Distinct traces of the adoption of rhyme are to be seen as early as the hymns of Hilary (died 368), and the system attained its greatest perfection in the 12th and 13th centuries. In refutation of the common opinion that the Latin hymnologists of the middle ages borrowed the art of rhyme from the Teutonic nations, Dr Guest brings the conclusive fact that no poem exists written in a Teutonic dialect with final rhyme before Otfried's *Evangelii*, which was written in Frankish about 870. Alliteration had previously been the guiding principle of Teutonic rhythms; but after a struggle, longer protracted in England than on the Continent, it was superseded by end-rhymes.

Rhymer. See THOMAS THE RHYMER.

Rhymney, a town of Monmouthshire, on the river Rhymney, 2½ miles W. of Tredegar. Pop. 11,700.

Rhynchocephalia. See SPHENODON.

Rhynchonella. See BRACHIOPODA.

Rhynchophora. See WEEVIL.

Rhynchops. See SKIMMER.

Rhyniaceae, a family of primitive pteridophytes included (along with Asteroxylon and Psilophyton) in the class Psilophytales; very simple land plants, found in a chert of Old Red Sandstone age at Rhyne in Aberdeenshire. The plants were fossilised where they grew, and the details of their structure so beautifully preserved that they almost equal living material. *Rhynia major* and *R. Gwynne-Vaughani* were rootless, leafless plants with rhizome and aerial stem, both branched and traversed by an extremely simple vascular strand, the rhizome having absorbent hairs and the vertical stem a few stomata. *Hornea Lignieri* differs in having a tuberous rhizome. The sporangia of the Rhyniaceae are modified ends of branches. In *Hornea* there is a central columella suggestive of mosses. The sporangium may even shave in the branching of the stem.

Rhyolite. See LIPARITE.

Rhys, SIR JOHN (1840–1915), born near Pontnewydd in Cardiganshire, served as a pupil teacher's apprenticeship, and after the course at Bangor Normal College kept a school in Anglesey down to the end of 1865, when he entered Jesus College, Oxford. He was elected to a fellowship at Merion in 1869, and next continued his studies at the Sorbonne, Heidelberg, Leipzig, and Göttingen, returning in 1871 to become inspector of schools for Flint and Denbigh. In 1877 he was appointed professor of Celtic in the University of Oxford, in 1881 was elected a fellow, and in 1895 principal, of Jesus College. His *Lectures on Welsh Philology* (1877) and *Celtic Britain* (1882) confirmed a reputation already gained by contributions to

Kuhn's *Beitrag zur vergl. Sprachforschung*, the *Rome Celtique*, and the *Archæologia Cambrensis*. He gave the Hibbert Lectures on *Celtic Heathendom* in 1886, and in 1889 the Rhind Lectures at Edinburgh. He wrote also *Studies on the Arthurian Legend* (1891), and *Celtic Folklore* (1901), and, with Brynmor Jones, *The Welsh People* (1900).

Rhythm may be defined as measured or timed movements, regulated succession. In order that a number of parts may constitute a pleasing whole, a certain relation or proportion must be felt to pervade them, and this exemplified in the arrangement of matter into visible objects, as in sculpture, architecture, and other plastic arts, produces a rhythm which is usually called *symmetry*. Rhythm applied to the movements of the body produces the *dance*. 'The rhythmical arrangement of sounds not articulated produces *music*, while from the like arrangement of articulate sounds we get the evidences of *prose*, and the measures of *verse*. Verse may be defined as a succession of articulate sounds, regulated by a rhythm so definite that we can readily foresee the results which follow from its application. Rhythm is also met with in prose; but in the latter its range is so wide that we never can anticipate its flow, while the pleasure we derive from verse is founded on this very anticipation.'

The rhythm of verse is marked in various ways. In Greek and Latin, during their classic periods, *quantity*, or the regulated succession of long and short syllables, was the distinguishing mark of verse. In the languages descended from these the rhythm depends upon *accent*. The recurrence of similar sounds, or *rhyme*, is also used, along with accent, to render certain points of the rhythm more distinct, as well as to embellish it. See METRE, RHYME; SAINTSBURY, *History of English Prose Rhythm* (1912); WILLIAM THOMSON, *The Rhythm of Speech* (1922).

Rhytina, a genus of Sirenia, akin to the dugong and manatee, of which only one species has been made known—the *Rhytina stelleri*, discovered by Behring and the naturalist Steller when they were wrecked on Behring Island in 1741, and described very fully by Steller. At that date they were extremely plentiful in this part of the northern Pacific, but were soon almost exterminated by the Russian hunters and traders. Nordenskiöld's inquiries led him to believe that individuals were seen till the middle of the 19th century. The species was distinguished by its large size, sluggishness, and its having horny plates in place of teeth. The skin was rough and hairless. The *Foca* expedition brought home many skeletons.

Riad. See WAHABIS.

Riazan, a town of Russia and capital of a government, stands near the right bank of the Oka, 115 miles by rail SE. of Moscow. A struggling, ill-built town of wooden houses, it sends wheat to Moscow. Pop. 41,500.

Ribalta, FRANCISCO (1550-1628), and JUAN (1597-1628), painters of the school of Valencia.

Ribble. See PRESTON.

Ribbon, Riband, or RIBBAND (a Celtic word). In Coventry the ribbon industry was started by Bird at the beginning of the 18th century. Coventry was at that time a city of 12,817 inhabitants. The population increased with the progress of the ribbon industry, until in 1861 it was 41,638. In 1860 there were 8886 looms; but the great competition of Basel and St Etienne then soon ruined the production of Coventry, for at these old centres labour was then much cheaper, the hours of work longer, and taste and style superior, particularly at St Etienne. Crefeld, Moscow, and especially

Paterson in New Jersey, are also manufacturing centres. See SILK, WEAVING.

Ribbon-fish, a name given to some members of a peculiar family (Trachipteridae) of bony fishes in the sub-order Acanthopterygii. They are abyssal or sometimes pelagic fishes. The body is much compressed and elongate; there is a continuous dorsal fin all along the back; the scales are minute or absent; the colour is silvery; the mouth is very protractile. The northern Ribbon-fish or Dealish (q.v.) (*Trachipterus arcticus*) may be 8 feet long or more; the Oarfish (*Regalecus glesne*) may be over 20 feet long. Both may have given rise to sea-serpent stories.

Ribeauville (Ger. *Rappoltsweiler*), a town in Upper Alsace (department of Haut Rhin), pleasantly situated amid vineyards at the west foot of the Vosges, 33 miles SSW. of Strasburg. Excellent wines are made; cotton and calico goods are manufactured. Pop. 5000.

Ribera, JUSEPE, called SPAGNOLETTO ('Little Spaniard'), was born at Jativa, near Valencia, on 12th January 1588, and died at Naples in 1656. He studied a few years with Francisco Ribalta at Valencia, then crossed the sea and continued his studies in Rome, Parma, and Modena. He settled in Naples, where he adopted the boldness of Caravaggio's style, and became the ablest painter among the *naturalisti*, or artists whose treatment of subjects was based on a vigorous, but generally coarse, representation of nature, in opposition to that formed on the study of conventional or academic rules. He attracted the attention of the viceroy, became court-painter, and was elected member of the Academy of St Luke at Rome in 1630. His realism is forcible and generally gloomy; he delighted to represent horrible and gruesome subjects, such as the martyrdoms of SS. Bartholomew, Januarius, and Lawrence, 'Promethiæ,' &c. Salvator Rosa and Giordano were his most distinguished pupils. He executed several etchings marked by force and freedom.

Ribes (from Arab. *ribaz*), a genus of shrubs of the Saxifragaceæ (sub-family Ribesioideæ), familiar examples of which are the Gooseberry and the Currant of gardens. The species are chiefly natives of the temperate and colder regions of the northern hemisphere; some are found at high elevations in tropical America and on the Pacific coast, from California to Chile. They are found also on the mountains of Northern India, in the colder regions of Africa and Europe, but western America is the home of the largest number of the species. They are twiggy shrubs, often, as in the Gooseberry (*R. Grossularia* and *R. speciosum*), armed with spines, clothed with deciduous alternate leaves, usually palmately lobed. The flowers are axillary in racemes, rarely solitary—small but often showy in the mass, as in *R. speciosum* and *R. sanguineum*. The calyx is the most conspicuous organ of the flower. It is persistent or adheres to the fruit after it is ripe, a feature very familiar in the gooseberry. The fruit is a berry, not in all species succulent, as it is in the gooseberry, currant, and others, but sometimes, as in *R. sanguineum*, almost entirely pulpy when ripe. The most important product of the genus is the fruit, which consists of sweet mucilage mixed with malic and nitric acids along with an astringent substance. See CURRANT, GOOSEBERRY.

Rib-grass. See PLANTAIN.

Ribs are elastic arches of bone, which, with the vertebral column behind, and the sternum or breast-bone in front, constitute the osseous part of the walls of the chest. In man there are twelve ribs on each side. The first seven are more directly connected through intervening cartilages with the

sternum than the remainder, and hence they are termed *vertebro-sternal* or *true ribs*; while the other five are known as *false ribs*, and the last two of these, from being quite free at their anterior extremities, are termed *floating ribs*. A glance at the skeleton, or at a plate representing the articulated

Fig. 1.—The Ribs, in situ.

1 and 2 are the upper and the middle parts of the sternum or breast-bone; 3, the costal cartilage; 4, the first dorsal, and 5 the last (or twelfth) dorsal vertebra; 6, the first rib; 7, its head; 8, its neck, resting against the transverse process of the first dorsal vertebra; 9, its tubercle; 10, the seventh or last true rib; 11, the costal cartilages of the true ribs; 12, the last two false ribs or floating ribs.

bones, will show that the ribs vary very considerably both in their direction and size. The upper ribs are nearly horizontal, but the others lie with the anterior extremity lower than the posterior; this obliquity increasing to the ninth rib, and then slightly decreasing. They increase in length from the first to the eighth, and then again diminish. The spaces between the ribs are termed the *intercostal spaces*. On examining a rib taken from about the middle of the series we find that it presents two extremities (a posterior or vertebral, and an anterior or sternal), and an intervening portion, termed the body or shaft. The posterior extremity presents a head, a neck, and a tuberosity. The head is marked by two concave articular surfaces divided by a ridge, the lower facet being the larger. These surfaces fit into the cavity formed by the junction of two contiguous dorsal vertebrae, and the ridge serves for the attachment of a ligament. The neck is a flattened portion proceeding from the head; it is about an inch long, and terminates at an eminence termed the tuberosity or tubercle, from whence the shaft commences. On the lower and inner part of this tubercle is a small oval surface, which articulates (as shown in fig. 2) with a corresponding surface on the upper part of the transverse process of the lower of the two vertebrae with which the head is connected. The shaft presents an external convex and an internal concave surface. A little external to the tubercle the rib is bent to form the angle, from which point the rib passes forwards and outwards, ultimately curving inwards to join its costal cartilage. The upper border of the rib is thick and rounded, while the lower border is marked by a deep groove, which lodges the intercostal vessels and nerve.

The ribs of Mammals are mostly connected, as in

man, with the bodies of two vertebrae, and with the transverse processes of the posterior one. In the Monotremata, however, they articulate with the vertebral bodies only; while in the Cetacea the posterior ribs hang down from the transverse processes alone. Their number on each side corresponds with that of the dorsal vertebrae. The greatest number, twenty-three, occurs in the two-toed sloth, while in the Chiroptera eleven is the ordinary number. In Birds each rib articulates by means of a small head with the body of a single vertebra near its anterior border, and with the corresponding transverse process by means of the tubercle. Moreover, each rib possesses a 'diverging appendage,' which projects backwards over the next rib, so as to increase the consolidation of the

Fig. 2.—A Front View of the Articulations of the Ribs with the Spinal Column:

1, 1, dorsal vertebra; 2, 2, intervertebral cartilages; 3, 3, anterior common ligament; 4, neck, and 5, head of rib; 6, 7, 8, flat bundles of ligamentous fibres (removed in the lowest rib, shown in the figure); 9, articulation between the tubercle of the ribs and the transverse vertebral process.

thoracic framework, necessary for flying. The dorsal vertebrae here never exceed eleven, and are commonly seven or eight in number, and the ribs proceeding from them are connected with the sternum not by cartilage, as in mammals, but by true osseous sternal ribs, which are regularly articulated at one end with the sternum, and at the other with the termination of the spinal ribs. In the Chelonian Reptiles the ribs (as well as the vertebrae and the sternum) deviate remarkably from the normal type, the lateral parts of the carapace consisting mainly of ankylosed ribs united by dermal plates. In the Crocodiles there are only twelve pair of true or dorsal ribs; while in the other Saurians, and in the Ophidians, the ribs are usually very numerous. In the Frogs there are no true ribs, the reason probably being that any bony element in their thoracic walls would interfere with the enormous thoracic abdominal enlargement which these animals periodically undergo at the breeding period.

In the language of the comparative anatomist, a rib is to be regarded as a *Pleuropophys*—one of the elements of a typical Vertebra (q.v.).

Fracture of the Ribs is a very common surgical accident, resulting from blows or falls upon the chest. Ribs may, moreover, be broken by mere pressure, as when persons are severely crushed in a crowd; and instances are on record in which, in the case of aged persons, the ribs have been actually fractured in violent coughing. The treatment consists in the application of a broad flannel roller round the chest, so tightly as to prevent, as far as possible, all movement of the

ribs, and to render the respiration abdominal rather than thoracic. The bandage must be prevented from falling by the addition of shoulder-straps; and in order to prevent the shoulder-blade from moving, and thus disturbing the broken ribs, some surgeons confine the arms to the side of the body. If one or both of the extremities of the fractured rib should perforate both layers of the pleura and wound the lung, or in rare cases when only the parietal layer of the pleura is injured, if the skin is also perforated, air may escape in the act of inspiration from the lung or from the exterior into the pleural cavity, and thence through the wound in the costal pleura into the cellular or areolar tissue of the trunk, giving rise to Emphysema (q.v.), in the form of a soft puffy swelling that crepitates and yields on pressure.

Ricardo. DAVID, an eminent political economist, was born in London, 19th April 1772. His father was a Jew, a member of the Stock Exchange, and brought up his son to the same business. An idiomation took place between them, when in 1793 young Ricardo married out of the Jewish persuasion and conformed to the Christian religion. He continued, however, to follow his father's profession with such success that at a very early age he realised a large fortune, while preserving an honourable reputation throughout his career in business.

In 1799 Ricardo had his interest in political economy awakened by the perusal of Smith's *Wealth of Nations*. His experience had well fitted him for the treatment of the special class of economic questions connected with banking and finance, and it was in the discussion of them that he first made his mark. In 1809 he brought out a pamphlet entitled *The High Price of Bullion a Proof of the Depreciation of Bank-notes*. As the title indicates, it was an argument in favour of a metallic basis. Other successful pamphlets followed. In 1817 appeared the work on which his reputation as an economist chiefly rests, *On the Principles of Political Economy and Taxation*. It is not a complete treatise on political economy, but may be described as a discussion of some of the principal factors of the science, such as value, wages, rent, &c. Ricardo is the conspicuous example of the abstract method of political economy. He was very deficient in the philosophic and historical training necessary for the wider investigation of economics. He approached the subject as a member of the Stock Exchange; and the economic conditions which he contemplated were those prevalent in his own day in England and in countries similarly situated, and particularly in the city of London. The main gist of his work is to embody economic principles in formulas, which for the most part have a general validity relative to the limited conditions which he thus recognised. His theories of Rent (q.v.) and of Wages (q.v.) have a general truth when regarded in this way; but when considered from a wider historical and philosophic standpoint they shrink greatly in significance. His theory of Value (q.v.) is still more defective.

In 1819 Ricardo entered parliament as member for Portarlington, and retained his seat till his death at Gatecomb Park, Gloucestershire, on 11th September 1823. He was too diffident to be an effective speaker, but his speeches, especially on matters of trade and finance, which he had made particularly his own, always commanded respect, and had a very considerable influence. Personally he was highly esteemed. His method in political economy is now almost universally abandoned. Even the strongest supporters of the traditional doctrines acknowledge that the value of his formulas has been greatly overrated, and that they

must undergo continual limitation, modification, and correction in the light of experience and of historic conditions. Yet his theories are eminently worthy of study, both as a phase in the development of economic science, and as illustrating a stage in the development of economic facts. The collected works of Ricardo were edited by McCulloch (1846), and collections of his letters were published in 1887, 1895, and 1899. See J. H. Hollander, *Ricardo, A Centenary Estimate* (1910).

Ricasoli. BARON BETTINO, Italian statesman, was born at Florence, 9th March 1809, and studied at Pisa and Florence. He was one of the best agriculturists in Italy, wrote books on the cultivation of the vine, the olive, and the mulberry, and for ten years worked successfully at the drainage of the Tuscan Maremma (q.v.). In 1859 he took a prominent part in opposing the government of the grand-duke (see ITALY), and when the latter fled Ricasoli was made dictator of Tuscany. He laboured with great energy for the unity of Italy, and when that end was accomplished was by Victor Emmanuel appointed governor-general of Tuscany. On the death of Cavour (1861) he was called to the head of the ministry; but his government was undermined by Rattazzi, and he resigned in March 1862. Ricasoli returned to power in June 1866, but was again obliged to retire in April of the following year. At the same time he withdrew altogether from public life; he died in Rome, 23d October 1880. Ten volumes of his letters and papers were published in 1886-94. See Life by Gotti (1894), and a study by Hancock (1926).

Ricci. MATTEO, founder of the Jesuit missions in China, was born at Macerata, 6th October 1552, studied at Rome, and in 1583 obtained leave to settle at Chow-king. He made his headquarters at Nanking, but was ultimately allowed to remove to Peking, where he built a church. He so mastered Chinese as to write dialogues and other treatises which received much commendation from the Chinese literati, and met with extraordinary success as a missionary. At his death, 11th May 1610, he was universally mourned. See JESUITS.

Riccina. See LIVERWORTS.

Riccio, or Rizzio. DAVID. See MARY (QUEEN OF SCOTS).

Rice (*Oryza*), a genus of grasses, having panicles of one-flowered spikelets, with two very small pointed glumes, the florets compressed, the palea strongly nerved, awned or awnless, six stamens, and two feathery stigmas. The only important species is Common Rice (*O. sativa*), one of the most useful and extensively cultivated of all grains, supplying the principal food of nearly one-third of the human race. It seems to be originally a native of the East Indies, but is now cultivated in all quarters of the globe, and almost wherever the conditions of warmth and moisture are suitable. It is adapted to tropical and sub-tropical climates, rather to the latter than the former. Rice is an annual, varying from 1 to 6 feet in height. There are many other distinguishing characters of the varieties in cultivation, some having long awns and some being awnless, some when ripe having the chaff (*palaeae*) yellow, white, red, black, &c. The seed or grain of rice grows on little separate stalks springing from the main stalk; and the whole appearance of the plant, when the grain is ripe, may be said to be intermediate between that of barley and of oats. Rice requires a moist soil, sometimes flooded. In some parts of the East canals are carried along the sides of hills for the irrigation of land for the cultivation of rice. In South Carolina rice is sown in rows in the bottom of trenches, which are about 18 inches apart; the trenches are filled with water to the depth of several

inches, till the seeds germinate; then the water is drawn off, and afterwards the fields are again flooded for rather more than a fortnight to kill weeds. They are flooded again when the grain is near ripening. Marshy situations, where there is always the same abundance of water, are not so suitable for rice as those in which the supply of water is regulated according to the season and the growth of the plant. In Europe the cultivation of rice is carried on in the plains of Lombardy and in Valencia in Spain. The introduction of rice into

the United States took place only about the middle or close of the 17th century, and now more than half the crop comes from Louisiana. The chief rice-producing countries in the world are India and China. Japan comes third. Rice is also extensively grown in Indo-China, Java, Siam, Egypt, and Brazil.

The wild rice, plentiful in the marshy tropical countries of southern Asia as well as in northern Australia, is without doubt the plant from which all our forms of cultivated rice have been derived. Most modern authorities regard India as the first home of rice, though some say it was originally derived from China. It has been cultivated in India from time immemorial. There are as many as 1300 names of rice, and, though very many of these are merely local

synonyms, a large number unquestionably correspond to intrinsic and seasonal distinctions. The obvious differences in the grain itself are indeed very remarkable. In colour the specimens range from a bright golden hue through almost every gradation of tint to black; and in regard to size also they vary greatly. But all these forms of rice are referable to a very few well-marked and constant varieties of *O. sativa*, the result of seminal variation commonly observed in plants that have been long brought under cultivation. Rice in the husk is called *Paddy* in India.

Rice is husked, quickly dried, and usually polished before being brought to market. Polishing, however, deprives it of a valuable vitamin (see BERBERI, VITAMINS). Special milling machinery is required for removing the inner skin of the rice grain, and a large quantity of the grain is badly broken in the process, being saleable only as broken rice or rice-flour. Good Indian rice has the following composition: Moisture, 15.50 per cent.; nitrogenous matter, 7.41; starch, 78.10; fatty or oily matter, 0.40; ash, 0.59. Rice contains a smaller amount of nitrogenous elements than any other grain (wheat having as much as 22 per cent.); it is also deficient in fatty matter, and if taken by itself is less nutritious than other grain-food (see FOOD); but combined with fatty nitrogenous substances it is a valuable food-stuff. It is believed to furnish more food for man than any other grain, especially in Chinese regions; but it is not, as is commonly supposed, the chief food-supply of India, where, save in certain favoured areas, millet is the principal food-stuff. Owing to the small quantity of gluten which it contains, it is capable by itself only of an imperfect fermentation, and is unfit for being baked into bread. It is, however, in many countries subjected to fermentation by

help of added ferments of various kinds. The beer made from rice by the Japanese is called *Saki*, and is in general use among them. Several kinds of *Rice wine* are made by the Chinese and Japanese, some of them highly esteemed and very intoxicating; spirit is distilled from the lees. Some of the common Arrack (q.v.) of the East is made from rice; and rice is also largely employed by distillers in Britain.

Rice Starch is made in considerable quantity in Britain, and is used in laundries and muslin manufactures. It has one-fourth more starch in its composition than wheat, hence the preference given to it by starch makers, both from its cheapness and larger yield. The straw of rice is used to make straw-plait for hats and the straw shoes of Japan. The refuse of rice, which remains when it is cleaned for the market, and consists of the husk, broken grains, and dust, is valuable as food for cattle. It is known as *Rice-meal* and *Rice-dust*.

Canada Rice (*Zizania aquatica*), the Wild Rice or Indian Rice of North America, is a species of grass quite different from the true rice, and of a different genus. It is common in North America, and particularly abundant in the north-western parts, growing in many places on shallow water, often on the margins of lakes. It has a culm 7 to 8 feet high, with broad diffuse leaves, and a large terminal panicle of male flowers, with a spike of female flowers at the summit. The flowers have six stamens. The seeds are about half an inch long, slender, farinaceous, affording very good meal, and are much used by the Indians where the plant abounds.

Rice, JAMES, novelist, for nine years collaborator with Sir Walter Besant (q.v.), was born at Northampton in 1843, studied at Cambridge, drifted from law into literature, and became proprietor and editor of *Once a Week*. He died in London, 25th April 1882.

Rice-bird, a name given to the Bob-o link (q.v.), as also to a popular cage-bird, the so-called Java Sparrow (*Padda oryzivora*), really a kind of finch.

Rice-paper, a paper made in China with layers of *Pistia* (*Aralia*) *papyrifera*, a tree peculiar to the island of Foumoua. The pith is sometimes 1 to 1½ inch in diameter. By carefully cutting this pith spirally with a very sharp knife it is opened out into a sheet of snowy whiteness. When the curl has been removed by weighting, or by flattening in a press, it is ready for use. It is chiefly employed for making coloured drawings on. When dyed it can be made into the most perfect artificial flowers. Another kind is made from the pure white root of the leguminous plant *Escipomene paludosa*. But the so-called 'rice-paper' used for cigarettes is made from linen trimmings.

Rich, EDMUND. See EDMUND (ST).

Richard I., king of England, surnamed CŒUR DE LION, was the third son of King Henry II. and his wife Eleanor of Aquitaine. He was born on 8th September 1157, either at Oxford or at Woodstock, but was brought up amongst the knights and troubadours of Poitou, in Aquitaine, with which duly, his mother's patrimony, he was whilst still a child invested by his father. In England Richard did not spend in all his life a full twelvemonth; after he became king he spent only twenty-six weeks in his kingdom, seventeen weeks when he landed to take the crown and to go through the coronation ceremony at Westminster, and nine weeks when he came back from his imprisonment. It may indeed reasonably be doubted whether he could speak English. A favourite of his unprincipled mother, he was in-

Rice (*Oryza sativa*):
b, a panicle in seed; c, a
flower; d, a seed.

duced by her to join his brothers Henry and Geoffrey in their rebellion (1173) against their father (see HENRY II.). Henry II. had his eldest son, Prince Henry, crowned king as his successor during his own lifetime; and in 1183 he ordered that his younger brothers should do homage to him. Richard obeyed with the greatest reluctance; thereupon the ungrateful Prince Henry at once picked a quarrel with him, and marched an army into his duchy of Aquitaine. King Henry hastened to the assistance of the young duke, whilst the other brother Geoffrey sided with the prince. But the sudden sickness and death of the ingrate put an end to the quarrel. In the spring of 1189 Richard was in his turn in arms against his father. Philip of France, the pertinacious foe of King Henry, mingled in the strife; and eventually Richard joined forces with his father's enemy, did homage to him, and took the field against the old king. A reconciliation was rendered more difficult because of Richard's jealousy of John, his father's favourite.

Richard became king of England, Duke of Normandy, and Count of Anjou on 5th July 1189, and was crowned king of England on 3d September following. But he had already taken the vows of the crusader; and, besides his coronation, he had another object in coming to England: he wanted to raise funds for his crusade. He effected this latter purpose in a brief space of time by selling whatever he could get a purchaser for. About midsummer 1190 he met Philip of France at the rendezvous, Vezelay in France; but from Lyons he made his way by a different route from Philip to Messina in Sicily. Both kings spent the winter at that city, and their mutual jealousy came within a hair's-breadth of a rupture. The throne of Sicily had just been seized by the Norman Tancred, an illegitimate son of King Roger, though the lawful heir was Henry of Hohenstaufen, son of Frederick Barbarossa, and afterwards the Emperor Henry VI. Moreover, Tancred detained in custody Johanna, widow of the late king (William the Good) and sister of Richard I., together with her very large dowry. But he made his peace with Richard by giving up to him his sister and her possessions, and by betrothing his little daughter to the boy Arthur (son of Richard's dead brother Geoffrey), whom Richard now declared to be his heir. On his way to Palestine in the spring of 1191, part of the fleet of the English king was driven on to the island of Cyprus, and the crews were most inhospitably treated by the reigning sovereign, Isaac Commnenus, a nephew of the emperor of Byzantium, who had revolted from his liege lord. Richard sailed back from Rhodes, routed Isaac in battle, deposed him, and gave his crown to Guy of Lusignan. In Cyprus, too, he married Berengaria of Navarre, whom his mother had brought to him at Messina. At last, on 8th June, the English king landed near Acre, and shortly afterwards that stronghold surrendered, the siege having lasted two years. Richard took his full share of the jealousies, animosities, and disagreements, though not of the treacheries, that made the Christian crusading host a hotbed of commotion. The glorious exploits of Richard the Lion-hearted—his march to Joppa along the seashore, his approach upon Jerusalem at Christmas, his capture of the fortresses in the south of Palestine, his second advance in the summer of 1192 on Jerusalem (the city he never beheld), and his relief of Joppa—made his name ring throughout the East and excited the wonder and admiration of Christendom, but brought no real advantage to the crusading cause. Richard in September concluded a peace with Saladin for three years, three months, and three days, and in his impulsive, impatient way started off home

alone, without waiting for his army and fleet. A storm shipwrecked him near the north end of the Adriatic. In disguise he began to make his way through the dominions of his bitter enemy, the Archduke of Austria. He was recognised, seized, and handed over to the Emperor Henry VI. (March 1193). The emperor demanded a heavy ransom for his release, but promised to give him the kingdom of Arles in addition to his liberty. Richard's loyal subjects raised the money; and greatly to the chagrin of Philip of France and Richard's brother John, the captive king returned home (13th March 1194). In England in the meantime Long-champ (q.v.) had made himself so unpopular that Richard had been obliged to supersede him, appointing in his place Walter of Coutances, Archbishop of Rouen. It was John, however, who exercised the greatest power in the realm. And although he used his utmost endeavours to prevent Richard's return from his captivity, yet Richard generously forgave him. After distributing judicious rewards and punishments, raising what money he could, making arrangements for the governance of the kingdom, and being crowned again—the emperor is said to have forced his captive to resign his crown and take it back as a fief of the empire—Richard proceeded to France, and spent the rest of his life there, warring against Philip. England was governed in his absence by Hubert Walter, Archbishop of Canterbury, who by the measures he took to raise the vast sums demanded by his master trained the English people in habits of self-government. The most important constitutional advances made under Hubert's rule were the formulation of the methods for electing the county grand juries and an arrangement for keeping the pleas of the crown by officers who may be regarded as the forerunners of the modern coroner. Richard was shot, on 7th April 1199, by an archer of the Viscount of Limoges, whilst besieging that nobleman's castle of Chalus-Chabrol, and was buried in the abbey church of Fontevraud.

Richard cannot be called a good king; his only thought of his subjects was how to get money from them. He was not a faithful husband; he was an undutiful son. Yet, on the other hand, he treated his perfidious brother John in the most forgiving spirit, and was not incapable of noble and generous acts. His impulsive, hot-headed temperament made him at times cruel, but never vindictive. He was an adventurer, with a passionate love for contention and strife; he fought for warlike glory, not for victory or real advantage; he had all the personal courage and self-confidence of the born warrior; and a very large share of that careless indifference or magnanimity that is frequently associated with a bold and self-reliant character. In matters of dress and ceremony he loved magnificence, and was both ostentatious and extravagant. In person he was tall and ruddy, exceptionally strong, skilful in the use of his weapons. He was also something of a poet.

See BLONDEL; Stubbs, *Constitutional History* (vol. i., 1897); Ramsay, *Anglo-Norman Empire* (1903); Cathellier, *Philip II. August* (1910); Miss Norgate, *Richard the Lion Heart* (1924). Richard is the hero of Scott's *Talisman*, and figures also largely in *Tristan*. In a vigorous but coarse-grained Middle English romance (ed. Brunner; Vienna, 1913), he becomes a cannibal of preternatural parentage.

Richard II., king of England, the son of the Black Prince and Joanna of Kent, was born at Bordeaux on 6th January 1367, was acknowledged by parliament heir to the crown on the death of his father in 1376, and succeeded his grandfather, Edward III., on 21st June 1377. The government was entrusted to a council of twelve, from which the king's uncles, John of Gaunt, Duke of Lan-

caster, Edmund, Earl of Cambridge, and Thomas, Earl of Buckingham (afterwards Duke of Gloucester), were excluded. Nevertheless the central figure during the early years of this reign, as he had been during the last years of the preceding reign, was John of Gaunt, whose overreaching ambition and inability were a fruitful source of disquietude. He was on bad terms with the clergy and with the Londoners, and was viewed with great suspicion by the king and the commons; yet he was the most powerful man in the kingdom, having at his back the nobles and to some extent the Lollards. War was going on with France, but in a very weak and desultory fashion; the French ravaged the south coast at the time of Edward III's death, and truces were constantly being made for short durations. But this war cost money: so too did the extravagance of the court; and more was absorbed or wasted by the government, for which John of Gaunt was held by the nation at large to be mainly responsible. Consequently taxation was heavy. The imposition of a graduated poll-tax in 1380 provoked popular risings, directed principally against the gentry and landholders, in nearly all parts of the kingdom, at Whitsuntide in the following year. The insurgents destroyed the parks, attacked the minor houses, burned the court-rolls, and massacred the lawyers who had charge of them. The men of Essex and Kent, to the number of 100,000, marched upon London. The former body, whom the king met at Mile End on 14th June, consented to return home when the young monarch assured them he would grant their requests, and take measures to liberate the villains from bondage and to commute their personal services into fixed money rents. The men of Kent, after destroying the Savoy (the Duke of Lancaster's palace), burning Temple Bar, opening the prisons, and breaking into the Tower and slaying the Archbishop of Canterbury, met the king at Smithfield (15th). During the negotiations, William Walworth, the mayor of London, struck down Wat Tyler (q.v.), the leader of the insurgents. The king immediately rode amongst them, exclaiming he would be their leader, and granted them the concessions they asked. The risings in the other counties speedily collapsed when the people learned what the king had done; but during the autumn severe punishment overtook them. Seven thousand in all are said to have perished in the fighting and on the scaffold. The causes of this wide-spread and simultaneous uprising on the part of the mass of the rural population may be summarised as follows: there had been long continuance of heavy taxation; the villains resented the reimposition since the Black Death of personal services, and were anxious to become tenants of their little farms at a fixed rental; the free tillers of the soil had formed themselves into associations to defeat the Statute of Labourers (1349), which fixed the maximum and minimum of wages; the Lollard or Wyclifite preachers were denouncing the idleness and vices of the regular clergy, and they and others (as John Ball) were promulgating social doctrines calculated to make the common people discontented with their lot and hostile to the landholders; the country clergy complained of the tyranny of the church; the mismanagement of the war, and the incapacity and selfishness of the court party provoked much discontent; there were many discharged soldiers in the country; and moral and religious feeling were sunk to a low ebb. From the fact that the insurgents directed their enmity against himself and the advisers of the king, John of Gaunt saw that he could never hope to succeed in his ambitious schemes in England; and from this time he kept very much in the background, until in 1386 he carried himself and his restless plottings to Spain

and Gascony. Richard in 1390 made him Duke of Aquitaine for life. In 1385 Richard invaded Scotland, and took Edinburgh and burned it; but, not encountering the Scots, returned home. About the same year another coalition of the baronial party, headed by Thomas of Woodstock, Duke of Gloucester, began to oppose the king and his chosen friends. They impeached several of them before the Merciless Parliament (1388), and secured convictions and executions. But on 3d May 1389 Richard suddenly declared himself of age, and proceeded to govern on his own responsibility. For eight years he ruled as a moderate constitutional monarch, and the country enjoyed peace—hostilities with France were not renewed after 1388—and was fairly prosperous. But in 1394 Richard's first wife, Anne of Bohemia, whom he had wedded in 1382, died, and two years later he married Isabella, daughter of Charles VI. of France, a girl of eight. From that time he seems to have adopted very largely French tastes, manners, and ideas. At all events, in the parliament of 1397 he began to assert the pretensions of an absolute monarch. On 8th July he had Gloucester, Arundel, and Warwick arrested on the charge of conspiring against the crown. Arundel was beheaded; Gloucester was sent a prisoner to Calais, and died there in prison, probably murdered, a fortnight after his arrest; and Warwick was banished to the Isle of Man. Thomas Arundel, Archbishop of Canterbury, was also banished. In the following year an obsequious parliament granted to the king the subsidy on wool for life, and delegated all its authority and power to a commission of eighteen members, all supporters of the king. Richard soon aroused the slumbering discontent of his subjects by his unjust methods of raising money, principally by means of forced loans, and by his arbitrary and despotic rule. In the beginning of 1398 the Duke of Norfolk and the Duke of Hereford (Henry, son of John of Gaunt) were accused to the king of having spoken treason against him. Richard banished them. Norfolk for life and Hereford for ten years. In January 1399 John of Gaunt died, and Hereford succeeded him as Duke of Lancaster; but the king refused to give up to the exile the lands of his dead father. Richard in May went over to Ireland, which he had previously visited at the head of a military expedition in 1394-95. Henry of Lancaster seized upon the opportunity afforded by the king's absence, and landed on 4th July (see HENRY IV.). Richard at once hurried back, but had neither heart nor power to withstand his cousin. He submitted to Lancaster at Flint (19th August), was carried to London, and placed in the Tower. On 29th September he resigned the crown, and on the following day was likewise deposed by the parliament, which chose Henry of Lancaster as his successor. A month after his resignation Richard was condemned to perpetual imprisonment by parliament. His fate is wrapped in obscurity, beyond the almost certain fact that he met a violent death, for which it is not altogether clear that Henry IV. was responsible. A month after Henry's accession some noblemen of Richard's party formed a conspiracy to restore Richard to the throne, but their purpose was discovered. No doubt this decided the fate of Richard; at all events, authentic history knows nothing more about him from this time. According to different accounts, either he was murdered in Pontefract Castle, or he starved himself to death, or he escaped to Scotland and died there a lunatic. By nature he seems to have been passionate, impulsive, and excitable; but though capable of bold and energetic action on occasion, his habitual mood was one of indolence. He had a good insight into men's characters; but suffered himself to be

influenced by those about him, and generally lacked the will and the steadfast resoluteness to act up to his own better judgment.

See *The Houses of Lancaster and York*, by J. Gairdner (1874); Stubbs's *Constitutional History*; Shakespeare's *Richard II.*; Ramsay's *Genesis of Lancaster* (1913) Oman's monograph on *The Great Revolt of 1381* (1906).

Richard III., king of England, was the son of Richard, Duke of York, a descendant of Edmund, Duke of York, fifth son of Edward III., and was born, the eleventh out of twelve children, in Fotheringlay Castle on 21 October 1452. After the defeat and death of his father in 1460 he was sent, along with his brother George, to Utrecht for safety, but returned to England after his elder brother Edward won the crown (1461). Two years later he was created Duke of Gloucester, his brother George being made Duke of Clarence. In the final struggle between the York and Lancaster factions he took an active share: he led the van at the battle of Barnet, rendered valuable aid in winning the fight of Tewkesbury, and is believed on fairly good evidence, to have had a hand in the murder of Prince Edward, son of Henry VI., who was slain after that battle. All through the reign of Edward IV. he gave valuable and faithful support to his brother, and was rewarded by him with every confidence, and with numerous high offices. He was believed to have been concerned in the murder of Henry VI. in the Tower on 21st May 1471; but the evidence, although strongly pointing in that direction, is not conclusive. In the following year he married Anne, the younger daughter of Warwick the King-maker, who had been betrothed to the murdered Prince Edward. This alliance was greatly resented by Clarence, who had married the elder sister, and wished to keep all of Warwick's vast possessions in his own hands. Clarence quarrelled too with King Edward, who in 1478 procured his impeachment by parliament. The refractory duke was put to death privately in the Tower on 18th February. Of this judicial murder Gloucester is likewise accused; but the evidence for his complicity is very slight. In 1482 he was put in command of the army that invaded Scotland. Along with the Duke of Albany he entered Edinburgh; but his one warlike achievement was the capture of Berwick town and castle. In the following year, whilst still in Yorkshire, he heard of King Edward's death (9th April), and learned that he himself had been named guardian and protector of his son and heir, Edward V., then aged thirteen. On his way south the Protector arrested Earl Rivers and Lord Richard Grey, the uncle and step-brother of the young king, and confined them in his northern castles. All who were of the old nobility, and resented the rise of the Woodvilles, rallied round Richard. Whether this accession of strength first suggested to him the idea of making himself king, or whether he had conceived it before, cannot of course be known; but certain it is that from this time Richard of Gloucester schemed for the crown, and by craft, boldness, and utter unscrupulousness carried his project into execution.

The arrest of Rivers and Grey had put the king entirely into his hands, for the queen-mother had hastened to take sanctuary at Westminster. On 13th June Gloucester suddenly accused Lord Hastings, an influential member of the council, of treason, arrested him there and then, and had him instantly beheaded. The 'crime' for which Hastings died was changing sides from Richard to the Woodville party. On 16th June the queen-dowager was induced to give up, at the demand of Richard and the council, her other son, the little Duke of York. He was put into the Tower to keep his brother, the king, com-

pany. On the Sunday following (22d) a certain Dr Shaw preached at St Paul's cross that the children of Edward IV. were illegitimate, nay, that Edward IV. himself and his brother Clarence were both born out of lawful wedlock. Three days later the parliament desired Richard to assume the crown; on the next day (26th June 1483) he declared himself king, and on 6th July was crowned in state by Cardinal Bourchier. Rivers and Grey were executed at Pontefract on 25th June. In point of form Richard was a duly elected king, and Edward V. had not yet been crowned; all the same, his accession was *de facto* an usurpation. Richard's principal supporter all through, from the date of Edward IV.'s death, had been the Duke of Buckingham, a descendant of the Duke of Gloucester who was privily slain at Calais when Richard II. was king. Shortly after his coronation Richard set out on a tour through the kingdom, and during the course of it he was surprised by the intelligence that Buckingham was plotting with the friends of Henry Tudor, Earl of Richmond (afterwards Henry VII.), the chief representative of the House of Lancaster, to effect his overthrow and proclaim Henry king. But the attempted rising soon collapsed, and Buckingham was taken, and on 21 November executed. It seems to have been shortly before this that Richard contrived the foul crime that has branded his name with infamy, and that caused himself inextinguishable remorse to the day of his death—the murder of his nephews in the Tower. The deed was done so secretly, by Sir James Tyrrell, one of Richard's devoted followers, and a couple of hirelings, that the nation did not know of it until some time after (see EDWARD V.). Indeed, the very fact of their murder has been seriously called in question, though not until much later times. But from the days of Richard himself he was popularly believed to have effected his nephews' destruction, and evidence supports the popular opinion. During the remainder of his short reign Richard directed all his energies to baffling the plans of Richmond, and to making preparations to meet the invasion which he saw to be imminent. But he was rapidly losing his hold upon the nation, alarming and horrifying it by his crimes and tyrannous acts. Henry of Richmond at length landed at Milford Haven on 7th August 1485. Richard met him at Bosworth in Leicestershire on the 22d, and there lost his kingdom and his life, fighting bravely like a king, crown on head, in the midst of his foes (see HENRY VII.). The body of the slain king was subjected to great indignities, carried to Leicester, and there, after being exposed for two days, was buried in the Grey Friars churchyard.

Richard's was a strangely mixed character. His ruling passion was an inordinate craving for power, to gratify which he stopped at no crime, however heinous. He possessed many of the typical qualities of the best of the Plantagenets: a skillful soldier, of great ability and energy, brave, bold, reckless of consequences, fond of display, yet not incapable of nobler impulses. Had he been born the lawful heir to the throne, and succeeded to it peacefully, he would probably have been a great king; for he was a very capable ruler, aiming at the real welfare of his subjects, promoting justice, and furthering religion and morality. Yet circumstances, conflicting with his insatiable ambition, helped the evil tendencies of his nature to get the upper hand; and these grew and hardened as time went on, till his audacity and unscrupulousness were matched with a cunning and hypocrisy such as are seldom found united in one man. On the other hand, he unquestionably had great charm of manner, and knew how to inspire confidence even in those who had the best

reasons for distrusting him. He was liberal too, and, where his own personal ambition was not directly concerned, just and generous. He was also swayed by a lively sense of divine justice; and more than one religious institution owed its foundation to his bitter remorse for the murder of his nephews. Most of his subjects and contemporaries looked upon him as a monster of wickedness; others, however, cherished his memory as that of a wise and good ruler. The real man was probably not quite so black as the Lancastrian (Tudor) chroniclers have painted him, though their portrait is probably fairly accurate in its broad features. In person Richard was short of stature and slight of build, with one shoulder slightly higher than the other; but there is no evidence that he was a hunchback. His face was thin and intelligent, and in portraits wears a look of sadness.

The best biography is James Gairdner's *Life and Reign of Richard III.* (3d ed. 1898). Attempts to defend his memory from some of the foul crimes laid to his charge have been made by Horace Walpole, *Historic Doubts on the Life and Reign of Richard III.* (1768); J. H. Jesse, *Memories of King Richard III.* (1862); A. O. Legge, *The Unpopular King* (2 vols. 1885); and Sir Clements Markham, *Richard III.* (1907). None of them can be said to have been successful in making Richard out a good man or a good king. Sir T. More's *History of King Richard III.* (1513), though highly coloured and antagonistic, is full of interest and vivid pictures of the king. *The Paston Letters*, ed. by J. Gairdner (1872-75), convey a good impression of the life and manners of the period. Shakespeare's drama gives the popular idea of Richard.

Richard of Bury. See AUNGERVILLE.

Richard of Cirencester, an early English chronicler, whose life falls between 1335 and 1401. His name is found in 1355 in the list of monks of the Benedictine monastery of St Peter, Westminster. In 1391 he obtained a license from his abbot to visit Rome, and he died in 1401. The only known work of his extant is a poor compilation in four books, the *Speculum Historiale de Gestis Regum Anglie 447-1066*, edited for the Rolls series by Professor J. E. B. Mayor (2 vols. 1863-69). It is of some independent value for the history of Westminster Abbey and Edward the Confessor. But Richard's name is best known in connection with the notorious forgery, *De Situ Britannie*, long accepted, to the serious detriment of history, as an authoritative work on the antiquities of Roman Britain. This work was first printed in 1758 by its ingenious author, Charles Julius Bertram (1723-65), teacher of English in the naval cadets' school at Copenhagen, who professed to have discovered it in the Royal Library there. In the same volume were included the works of Gildas and Nennius, the title of the whole being *Britannicarum Gentium Historie Antiquae Scriptores tees, Ricardus Cornuensis, Gildas Badoniensis, Nennius Banchorensis*. A new edition of this treatise, with an English translation, appeared at London in 1849; a reprint forms one of the 'Six Old English Chronicles' in Boln's 'Antiquarian Library' (1848). Dr William Stukeley, with whom Bertram had corresponded since 1747, received the book warmly on its appearance; Gibbon comments 'a genuine knowledge of antiquity very extraordinary for a monk of the 14th century'; all the historians, even Lingard and Lappenberg, trusted it; and even so late as 1886 we find it gravely treated as an authority in a work by James Grant on the *Tactics of the Clans of Scotland*. Some later scholars, such as Guest, had doubted, if not condemned it, but its authenticity received its death-blow in the series of papers contributed to the *Gentleman's Magazine* (1866-67) by Mr Woodward, librarian of Windsor Castle. Again in Professor Mayor's preface the various sources of the forgery

are elaborately set forth, and everything satisfactorily accounted for but the credulity of its dupes.

Richard of Cornwall, second son of John, king of England, was born on 5th January 1209. In 1225-26 he and his uncle, William of Salisbury, commanded an expedition which recovered Gascony, and the next year he received Cornwall, as the result of a rising of the earls to compel the king (Henry III.) to make provision for him. He managed his money matters well, and his wealth, as well as his prudence, saved Henry in many an impending crisis. For some years he acted with the English barons, to many of whom he was closely related by his marriage with Isabel, Countess of Gloucester, daughter of the Earl of Pembroke. In 1232 he was one of the leaders in the opposition to Hubert de Burgh; and in 1238 he headed an armed rising provoked by the king's secret marriage of his sister to Simon de Montfort. But Richard was still heir to the throne, and the articles which Henry was prepared to sign, and which dismissed his foreign advisers, appeared to the earl to bind the king's hands too closely, and he drew back. In 1240-41 Richard was away on a crusade, and the next year he was with his brother in Gascony; and in 1244 he married Sanchia of Provence, sister of Queen Eleanor, and this second marriage drew him away from the baronage. In 1252 he refused the pope's offer to sell him the crown of Sicily; but in 1257 he was elected by a majority titular king of the Romans, and was soon afterwards crowned at Aix-la-Chapelle; and he was skilful enough to maintain a certain hold on Germany, lavishing his wealth to keep up his own position and the dignity of the empire. In the great struggle which took place between Henry III. and his nobles Richard at first acted as a peacemaker. Subsequently, however, he sided with his brother against Simon de Montfort; and he was taken prisoner at Lewes, and imprisoned for a year, until the battle of Evesham (1265) set him free. In 1267 he was a third time married, to Beatrice, niece of the Elector of Cologne. Richard died at Kirkham, 2d April 1272, broken-hearted at the loss of his eldest son, Henry, who was murdered at Viterbo by the Montforts, and immortalised by Dante. Two other sons died also without issue.

Richardson. CHARLES, lexicographer, was born in July 1775, studied law, kept school at Clapham, received in 1852 a pension of £75, and died 6th October 1865. His best work, *Illustrations of English Philology* (1815), led to his undertaking an English dictionary for the *Encyclopædia Metropolitana*, the first part of which appeared in January 1818. The project fell through, but Richardson's *New Dictionary of the English Language* at length appeared complete in two quarto volumes in 1837. The work was warmly received—French styled it 'the best dictionary in the language'—and at that time it deserved the praise. A later work was entitled *On the Study of Language: an Exposition of Tooke's Diversions of Purley* (1854).

Richardson. SIR JOHN, naturalist, was born at Dumfries, November 5, 1787, studied at Edinburgh University, became a navy-surgeon, served in the Arctic expeditions of Parry and Franklin (1819-22 and 1825-27), as well as in the Franklin search expedition of 1848-49, was knighted in 1846, married three, and died near Garsmer, June 5, 1865. The most valuable of his books were *Fauna Boréal-Americana* (4 vols. 1829-37) and *Ichthyology of the Voyage of H.M.S. Erebus and Terror* (1844-48). There is a Life by the Rev. John McIlraith (1868).

Richardson. SAMUEL, novelist, was born in 1689 in Derbyshire. Like Matthew Prior, he was

the son of a joiner; but unlike him, he made no effort to obscure his origin. 'My father,' he said, 'was a very honest man, descended from a family of middling note. My mother was also a good woman, of a family not ungentle.' His career is a curious exemplification of the truth of that Horatian precept which Thackeray chose for the motto of *Esmond*. It preserved to the end the characteristics of its outset. The man who was afterwards the moralist of Salisbury Court was as a boy the 'Gravity' and 'Serious' of his school-fellows; the novelist who penned the interminable epistles of Clarissa and Harriet Byron was as a youth the favoured and indefatigable amantissimus of half the girls in the neighbourhood, acquiring in this aimless office something of that strange knowledge of the minutest mechanism of the feminine mind which is so conspicuous a feature of his genius. He says of himself that he had only 'common school-learning;' but he appears to have been at Christ's Hospital. In 1706, at the age of sixteen, he was bound by his own wish to John Wilde of Stationers' Hall, a printer, with whom he served the usual period. Allington Wilde, whose daughter he married, was also a printer, but was quite a distinct person from his master. From 1713 to 1719 he worked as a journeyman printer. In the latter year he opened an establishment of his own in the centre, and later in the north-west corner (No. 11) of Salisbury Square, then Salisbury Court. His printing-office and warehouses were in Blue Ball Court, on the east side of the Square. In a sober, methodical way he continued to prosper, perfecting his faculty for letter-writing in various ways, and serving the humbler needs of literature by diligent compilation of prefaces, indexes, advertisements, and the like. He printed more than one newspaper, and by the favour of Mr Speaker Onslow obtained the printing of the journals of the House of Commons, twenty-six volumes of which passed through his establishment. Then, in 1740, came the opportunity which transformed him into a literary celebrity. To use his own words, 'he accidentally slid into the writing of *Pamela*.' He was over fifty when two bookselling friends invited him to prepare a volume of familiar letters 'in a common style, on such subjects as might be of use to those country readers who were unable to indite for themselves.' He caught at the idea, superadding another. 'Will it be any harm,' he said, 'in a piece you want to be written so low, if we should instruct them how they should think and act in common cases?' Hence sprang *Pamela*, published in November 1740. Its title was as leisurely as its method: '*Pamela; or Virtue Rewarded*. In a series of familiar letters from a beautiful young damsel to her parents. Published in order to cultivate the principles of virtue and religion in the mind of the youth of both sexes. A narrative which has its foundation in truth; and at the same time that it agreeably entertains by a variety of curious and affecting incidents, is entirely divested of all those images which, in too many pieces calculated for amusement only, tend to inflame the minds they should instruct.' The moral note is explicit enough on the good printer's title-page; but for all that *Pamela* is by no means *ad usum Delphini*. Its vogue, in a coarser and rougher age than ours, was nevertheless extraordinary. Not to have read of Richardson's exemplary heroine was 'as great a sign of want of curiosity, as not to have seen the French and Italian dancers.' Divines extolled her from their pulpits; Pope declared she would do more good than their discourses; fine ladies triumphantly exhibited her popular chronicles at places of amusement; and in remote country villages, when at last she was happily married, her rustic admirers set

the bells a-ringing. In February followed a second edition; a third succeeded in March, and a fourth in May. Grub Street, fastening promptly upon this unexampled popularity, hastily put together for sequel a *Pamela in High Life*, which had the unfortunate effect of seducing Richardson into two supplementary volumes, now deservedly forgotten; and then Henry Fielding fluttered the Salisbury Court dovecot by producing what Richardson and his coterie regarded as the 'lewd and ungenerous engraftment' of *Joseph Andrews*. Happily, however, both for Richardson and posterity, he speedily discarded burlesque for the immortal character of Parson Abraham Adams.

Eight years elapsed before Richardson published another novel. But during this time, consoling himself for the coarse sallies of the irreverent by the 'soft adulation' of a little circle, chiefly of the gentler sex, who gathered round him in his suburban home at Hammersmith, he continued, either in his snug writing-closet or his summer-house, to work placidly at his masterpiece—*Clarissa; or the Adventures of a Young Lady*, known generally as *Clarissa Harlowe*. Virtue, in this performance, was not 'rewarded,' but ruined. The heroine is nevertheless drawn with a tenacity of insight to which *Pamela* could scarcely pretend; and the chief male character, that of Lovelace, though more of an abstraction, is scarcely inferior. Johnson declared the book to be the first in the world for its knowledge of the human heart; and even Fielding did not refuse his tribute: 'Such simplicity, such manners, such deep penetration into nature, such power to raise and alarm the passions, few writers, either ancient or modern, have possessed of' (*Jacobite Journal*, No. 5). Lesser voices swelled the chorus with greater energy, and it was repeated across the Channel with Gallic enthusiasm. The high-priest of sentiment, Diderot, did not scruple to name its author with Homer and Euripides; and as if to prove that this was no momentary Anglomaniac, in a later day the poet Alfred de Musset proclaimed it to be 'le premier roman du monde.' But from France also came its compactest condemnation. 'La nature,' said D'Alembert, 'est bonne à mûrir, mais non pas jusqu'à l'ennui.'

Having drawn the ideal woman in *Clarissa*, Richardson proceeded, some five years later, to portray, in *Sir Charles Grandison*, the perfect man—'the man of true honour.' This is a work of much greater ability than *Pamela*, but still far below *Clarissa*. It has, moreover, no central story strong enough to reconcile the reader to the polix impeccability of its superlative hero, who Taine, with an unwonted burst of critical levity, suggests should be stuffed and canonised for his wearisome good qualities. Besides a solitary essay in Johnson's *Rambler* (No. 97), and the voluminous but not very interesting correspondence published (with an excellent memoir) by Mrs Barbauld in 1804, Richardson left no other literary remains of any importance. In later life a nervous habit grew upon him, which terminated in 1761 by a fit of apoplexy, of which he died. He has left his own portrait in his letters to Lady Bradslough (*Corr.* ii. 206, and iv. 290); but it might almost have been deduced from his letters. He was a sentimental, purring, methodical, well-meaning little man, domesticated and affectionate, whose fitting environment was feminine society of the sympathetic sort; and he has repaid the gentle caresses with which his worshippers tempered the wind of adverse criticism to his sensitive soul by depicting their sex in return with a patience, a discrimination, a sustained analysis of secret spring and motive which it has been given to no other male author, living or dead, to achieve. It is the most unequivocal testi-

mony to his native genius that his impracticable method of telling his story by correspondence and his intolerable circumstantiality and diffuseness (he thinks nothing of an epistle of fifteen pages, and Clarissa takes nineteen for her will) have served only to emphasise and intensify the reality of his creations.

There was a reprint of Richardson's novels, with preface by Sir Leslie Stephen, in 1883. Mrs Barbauld prefixed a biography to his *Correspondence* (1804). See Miss Clara Linklater Thomson's 'biographical and critical study' (1900); Cazamian in the *Cainbr. Eng. Lit.*, x. (1913); *Richardson* by Austin Dobson (1902).

Richborough. See SANDWICH.

Richelieu. ARMAND JEAN DUPLESSIS, CARDINAL, DUC DE, one of the greatest statesmen of France, was born of a noble but impoverished family at Richelieu, 12 miles SSE. of Chinon, September 5, 1585. He abandoned a military career for the church, in order to keep in the family the bishopric of Luçon, to which he was consecrated at twenty-two. Representative of the Poitou clergy at the States-general in 1614, he attracted the notice of the queen-mother, and rose in 1616 to be secretary at war and foreign affairs; but the downfall of Marshal d'Ancre, the queen-regent's favourite, in April 1617, sent him back to his diocese. At length in August 1620 the queen-mother and the young king were reconciled, mainly through the agency of the celebrated Capuchin Father Joseph—'l'Éminence grise' of later days, till his death in 1638 the intimate friend of Richelieu. The latter showed much tact and patient forbearance in his measures; he formed an alliance with the powerful Duc de Luynes, and in 1622 was named cardinal, in 1624 minister of state. This position he retained to the end of his life, in spite of countless court intrigues, and ere long the most powerful open and secret opposition from the queen, Gaston, Duke of Orleans, and a host of minor intriguers, first among whom was the too famous Duchess de Chevreuse. His first important measure was the blow to Spain of an alliance with England, cemented by the betrothal (1625) of the king's sister Henrietta with Charles, then Prince of Wales. In the Valtelline war he cleared the country of the Spanish and papal troops, but was unable to pursue his advantage, and had to submit to the terms of the peace of Monzon (1626). His next task was to destroy the political power of the Huguenot party. After a fifteen months' siege, which he conducted in person, concentrating all his energy upon the task, the great stronghold of La Rochelle was starved into submission, 30th October 1628. He next turned to crush Rohan and the Languedoc rebels, and destroyed the proud walls of Montauban, last refuge of Huguenot independence. Early in 1630 he entered Italy with a splendid army, himself in command, and soon reduced Savoy to submission. Meanwhile he plunged into dark and tortuous intrigues with the Italian princes, the pope, and with the Protestants of the north against the House of Austria. He promised a large subsidy to Gustavus Adolphus, and, through the masterly diplomacy of Father Joseph at the Ratisbon Diet in June 1630, succeeded in persuading Ferdinand to dismiss Wallenstein. The first treaty of Cherasco (April 1631) ended the Italian war, the second gave France the important strategic position of Pinerolo. Just before this final triumph Richelieu had successfully surmounted the greatest danger of his life—a great combination formed for his downfall by the queen-mother, Gaston of Orleans, the House of Guise, Bassompierre, Créquy, and the Marillacs. She tried to bully the king by her violence, but Richelieu followed his master to Versailles, and again had the whole power of the realm placed entirely in his hands. So ended 'the

Day of Dupes' (11th November 1630). The queen-mother fled to Brussels, Bassompierre went to the Bastille, Gaston fled to Lorraine. The cardinal was now made duke and peer, and governor of Brittany. Further intrigues and attempted rebellions by the emigrant nobles and governors of provinces were crushed with merciless severity—Marillac and Montmorency and other nobles were sent to the block. Meantime Gustavus Adolphus had run his brief and brilliant course; and his death at Lützen removed an ally with whom it might have become difficult to reckon. In July 1632 Richelieu had seized the duchy of Lorraine. He continued his intrigues with the Protestants against Ferdinand, subsidising them with his gold, but till 1635 he took no open part in the war. In May of that year, after completing his preparations and concluding a close alliance with Victor Amadeus of Savoy, Bernhard of Saxe-Weimar, and the Dutch, he declared war on Spain, and at once placed in the field an army of 132,000 men. But his first efforts were singularly unsuccessful, and in 1636 Piccolomini and the Cardinal-Infante, governor of the Netherlands, entered Picardy, crossed the Somme, and threatened Paris itself. But in this hour of peril Richelieu rose to the height of his genius, and awoke a new and irresistible force as he threw himself upon the patriotism of France. With 30,000 foot and 12,000 horse he swept the enemy out of Picardy, while his ally Bernhard drove them across the Rhine, and in 1638 destroyed the imperial army in the decisive battle of Rheinfelden, a victory which opened to him the gates of the key-fortress of Breisach. The unexpected death of Bernhard threw the fruit of his victories into the hands of Richelieu, whose policy soon bore further fruit in the disorganisation of the power of Spain—revolts in Catalonia, and the loss of Portugal; the victories of Woffenbuttel (1642) and Kempten (1642) over the Imperialists in Germany; and at length in 1641 in Savoy also in the ascendancy of the French party. Another triumph that same year was the speedy collapse of the Imperialist invasion in the north by the Count of Soissons, who perished in the first battle. The failure to capture Tarragona was the one exception to the complete triumph of the cardinal's latest years.

But the hatred of the great French nobles to his rule had never slumbered, and Richelieu found safety alone in the king's sense of his own helplessness without him. He was firmly convinced that the only safe government for France was a strong absolutism uncontrolled either by the selfish ambition of the nobles or the constitutional legalism represented by the Parlement of Paris. The last conspiracy against him was that of the Grand-écuyer, the young Cinq-Mars, whose intrigues with Gaston, the Duke of Bouillon, and the Spanish court were soon revealed to the cardinal, the centre of a network of espionage which covered the whole of France. When the hour was ripe he placed in the king's hands at Tarascon proofs of the traitorous plot with Spain, and was given full powers as Lieutenant-general of the realm. Cinq-Mars and De Thou were at once arrested, and the wretched coward Gaston of Orleans hastened after his kind to buy his own security by betraying his accomplices. Cinq-Mars and De Thou were executed at Lyons in the autumn of 1642. But the great minister was himself dying in the hour of his greatest triumphs. Death had often drawn near him, but the strong will and fiery soul within his frail and feeble frame had thrust him aside and retained the fleeting life. He faced the inevitable at last with calm tranquillity—when the priest bade him forgive his enemies, he made answer, 'I have never had any other enemies than the state's.' We see the same inhuman impersonality in the

identification of himself with the state in his *Mémoires*—'I have been severe to some in order to be good to all. . . . It is justice that I have loved and not vengeance. . . . I wished to give to Gaul the limits that nature had marked out for her. . . . to identify Gaul with France, and wherever the ancient Gaul had been, there to restore the new.' He died 4th December 1642, bequeathing Mazarin to the king as his successor.

Richelieu built up the power of the French crown, he achieved for France a preponderance in Europe, and throughout life he moved onwards to his goal with the strongest tenacity of purpose, unmoved either by fear or pity. He destroyed the local liberties of France, and crushed every element of constitutional government, and his policy overwhelmed the citizens with taxation and made waste places some of her fairest provinces and most thriving towns. Our judgment of him will always differ according as we examine his end or his means—the public or the private man. He never sacrificed to personal ambition the interests of his country as these seemed to himself, but he often forgot in his methods the laws of morality and humanity. There is no need here to discuss the more fundamental question of whether his end was actually identical with the highest good of France—the best defence that even so redoubtable a Chauvinist as Henri Martin can offer is that he merely developed out to the full tendencies long rooted in French soil, and that no other ideal of a policy was then possible for France but a systematised absolutism under a beneficent despot. Nor have we sympathy to spare for the corrupt and selfish nobles whom he crushed with a severity so merciless that he drove twenty-one persons into exile, all of them the greatest names in France, banished sixty-five, several of these ladies, while seventy-three nobles were flung into prison, and forty-three were either beheaded or died in prison.

We know the face of Richelieu best from Philippe de Champaigne's picture in the Louvre, in which the energy of the model had passed into the hand of the artist. A pale apparition, the mere ghost of a great man in Michelet's phrase, neither flesh nor blood, but all intellect, as Quinet said of Voltaire, he looks down upon us still with that steady and penetrating eye and that imperious gesture that overawed the king and the proudest peers of France. The weakest point in Richelieu's character was his literary ambition and the extraordinary pains he took to construct a literary reputation. His own plays for the fate of which he trembled with anxiety, sleep in safe oblivion, but his *Mémoires* are still read with interest, forming a subtle and elaborate panegyric upon himself, so that Michelet says in his paradoxical manner, yet not without truth, 'If one would not know Richelieu, one should read his Memoirs.' He founded the French Academy. His Correspondence and State Papers, edited by d'Avenel, fill 8 vols. of the *Collection de Documents inédits sur l'Histoire de France* (1853-77).

See the article FRANCE: Capefigue, *Richelieu, Mazarin, et La Fronde* (24 ed. 1844), and *Le Card. de Richelieu* (1865); Dussieux, *Le Card. Richelieu* (1885); d'Avenel, *Richelieu et la Monarchie absolue* (4 vols. 1884-95); Hanotaux, *Histoire du Card. de Richelieu* (1893-1903).

Richmond, an ancient municipal borough in the North Riding of Yorkshire, on the left bank of the deep-channelled Swale, 49 miles NW. of York. Its Norman castle (1072-1146) has a very fine banqueting-hall and a keep 100 feet high. Other buildings are the parish church (restored by Scott, 1860), with good wood-carvings; Queen Elizabeth's grammar-school (1567; rebuilt 1849-68); the market-house (1854); and the Perpendicular tower of a Franciscan friary, founded in

1258. The racecourse (847 feet above sea-level) commands a magnificent view. The military centre Catterick Camp is about 3 miles off. Till 1867 Richmond returned two members, and then till 1885 one. Pop. 4000. The earldom of Richmond was conferred by the Conqueror on his kinsman, Alan Rufus, son of the Count of Brittany, and, coming into the possession of the crown through John of Gaunt, was granted by Henry VI. to the father of Henry VII. Henry VIII. created his natural son, Henry Fitzroy (1517-36), Duke of Richmond, as Charles II. did his natural son, Charles Lennox (1672-1723), the ancestor of the Dukes of Richmond and Gordon.

Richmond, a town of Surrey, 8½ miles WSW. of London (by rail 92, by river 16), stands partly on the summit and declivity of Richmond Hill, and partly on the level right bank of the Thames. The Terrace, stretching along the brow of the hill, commands an unrivalled prospect of hill and dale, woodland and winding stream; and one of the finest river views in England may be gained from Richmond Bridge, which, 100 yards long, was built in 1771-77. Only a gateway remains of the ancient royal palace of Sheen, where died Edward III., Richard II.'s queen, Anne of Bohemia, Henry VII., and Elizabeth. It was rebuilt by Henry V. and Henry VII. (1499), who renamed the place Richmond after his own former earldom. That palace, which has memories also of Wolsey, Charles V., and many others, was dismantled in 1648; but the splendid deer-park, formed by Charles I. in 1634, remains. It covers 2253 acres; and its brick wall is about 10 miles in circumference. Scott here makes Jeanie Deans have her audience with Queen Caroline. The well-known 'Star and Garter', dating from 1738, largely destroyed by fire in 1870, but rebuilt in 1872-74, was demolished (1919) to make way for the palatial Star and Garter Home for Disabled Soldiers and Sailors (1925). At the parish church are buried the poet Thomson, Keats, Lady Di Beaneclerk, and Dr John Moore; and here, too, Swift's Stella was baptised. St Athlone's (1858) is a striking building by Scott, with a spire 195 feet high; and there are also a Wesleyan training college (1834), a public library (1881), &c.; whilst Richmond worthies other than those above mentioned have been Reynolds, Gainsborough, Collins, and Earl Russell. Market and nursery gardening is a chief industry. Richmond was incorporated as a municipal borough in 1890. Pop. (1861) 7423; (1881) 19,066; (1891) 22,684; (1921) 35,639. The borough includes Kew (q.v.) with its Botanic Gardens, and Petchesham.

Richmond (1) the smallest of the boroughs into which the city of New York (q.v.) is divided. —(2) Capital of Wayne county, Indiana, on the East Fork of Whitewater River, 69 miles by rail NNW. of Cincinnati, and 68 E. of Indianapolis. It was founded by the Society of Friends, who in 1859 established Earlham College here, for both sexes. There are manufactures of agricultural implements, machinery, boilers, flour, &c. Pop. (1880) 12,743; (1890) 16,608; (1910) 22,324; (1920) 26,765.

(3) The capital of Virginia, on the left bank of the James River (here crossed by a number of bridges), at the head of tide water, about 150 miles from its mouth, and 97 miles S. of Washington. It is a port of entry, with large docks. Richmond is picturesquely situated on a group of hills, the summit of one—Shoekoe Hill—being occupied by the capitol (1796), which contains valuable colonial archives and portraits; it possesses also a marble statue of Washington by Houdon, and in its grounds are statues of Henry Clay and 'Stonewall' Jackson, and the Washington monument, a

noble bronze group by Thomas Crawford. Patrick Henry is buried in St John's churchyard, and President Monroe in Hollywood Cemetery, where also is a Confederate monument 90 feet high. Other notable buildings are Chief-Justice Marshall's house, Jefferson Davis's house (now a museum of Confederate relics), Soldiers' Home, and Masonic Temple. In the city are the University of Richmond (1832) and two medical colleges. The James River Falls supply immense water-power for tobacco-factories, ironworks, machine and locomotive works, flour and paper mills, and fertiliser-works. Several railways meet at Richmond, which is a terminus also of the James River and Kanawha Canal. The chief exports are tobacco and flour. Richmond was founded in 1737, and became the capital in 1779. In 1861 it was selected as the Confederate capital, and from that period was the objective point of the Union armies in the east, and defended by General Lee with a large army and formidable lines of earthworks (which eventually extended for nearly 40 miles), until the seizure of the lines of supply by Generals Grant and Sheridan compelled its evacuation (2d April 1865) after almost a year's siege and a series of sanguinary battles. Pop. (1860) 37,910; (1900) 85,050; (1910) 127,628; (1920) 171,667.

Richmond, GEORGE (1809-96), was both a miniaturist's son at Brompton, came under Blake's influence, and distinguished as a portrait-painter, was successively A.R.A. and R.A.—His son, SIR WILLIAM BLAKE RICHMOND (1843-1921), portrait and mythological painter, was born at London, studied in Italy, became A.R.A., R.A., and Slade professor at Oxford. The St Paul's mosaics are his work.

Richmond, LEGH, born at Liverpool in 1772, studied at Trinity College, Cambridge, was appointed in 1798 to the joint curacies of Brading and Yaverland in the Isle of Wight, and died rector of Tisbury in Bedfordshire in 1827. He wrote on *The Fathers of the English Church*; and his *Dairyman's Daughter*, *Negro Servant*, and *Young Cottager* carried his name over the English world, and were collected as the *Annals of the Poor* (1814). See *Memoirs* by Grimshawe (1828).

Richter, EUGEN (1838-1906), born at Düsseldorf, became journalist in Berlin in 1864, and from 1867 was leader of the Radical party; as effective in speeches, pamphlets, and stories against the social democrats as he was against Bismarck.

Richter, HANS (1843-1916), born at Raab in Hungary, had been conductor in theatres at Munich, Budapest, and Vienna ere in 1879 he began his orchestral concerts in London. He co-operated with Wagner in the production of the *Nibelungen* performances at Bayreuth, and conducted the Halle orchestra from 1900 to 1911, when he retired to Bayreuth. He was a musical director of singular accomplishment and power.

Richter, JOHANN PAUL FRIEDRICH ('Jean Paul'), was born on 21st March 1763 at Wunsiedel in the sequestered pine clad Fichtelgebirge of North Bavaria. The imaginative boy was brought up in the idyllic sabbath-life of the mountain villages in which his father was pastor, went to school at the town of Hof, and in 1781 was sent to Leipzig University to study theology. But, like Lessing, he did not study theology; Rousseau and Voltaire, Swift and Sterne, Pope and Young, had much stronger attractions for him, and he too resolved to write books. He asserted his independence of custom by discarding the periwig and stiff necktie, wore his hair long, his shirt and vest open at the throat, and dressed him as he pleased. But he found it harder work to get bread than to write and assert his position as an emancipated youth.

Being poor, he got into debt all round, and in November 1784 fled secretly from Leipzig, to go and hide his head in the poverty stricken home of his mother (a penniless widow since 1779) at Hof. His first literary 'children' were satires; but he could get no publisher to introduce them to the world, until in 1783 Voss of Berlin gave him forty louis d'or for *The Greenland Law-suits*. The book was a failure. For three years Jean Paul struggled on at home, his mother spinning hard for bread, he helping with the few florins he earned by his pen. He read enormously, omnivorously, and sat hours making excerpts from the books he devoured—a practice he kept up from early boyhood to old age. These many folios of closely-written pages were the storehouses upon which he drew for materials when he came to write his romances. He took long rambles amongst the hills and forests, his hair flying in the wind, a book in his hand or a song on his lips, and a favourite dog at his heels. In the beginning of 1787 he began to teach the children of different families in the district, and of course taught by original methods. All this time he still went on writing, and during his nine years of tutorship produced, amongst other things, the satirical *Extracts from the Devil's Papers* (1789), *Fatbel's Journey* (1796), and *Freud's Complaint* (1796), the last two amongst the best examples of his satirico-humorous writings; the beautiful idylls *Dominic Wenz* (1793), *Quintus Fixlein* (1796; Eng. trans. by Carlyle, 1827), the *Parson's Jubilee* (1797), the first two perhaps the most finished things Jean Paul ever wrote; the grand romances *The Invisible Lodge* (1793), *Hesperus* (1795; Eng. trans. 1865), and *Flower, Fruit, and Thorn Pieces*, or *Siebenkas* (1796-97; Eng. trans. by Noel 1844 and 1871, by Ewing 1877); *Companerthal* (1797; Eng. trans. 1857), a series of reflections on the immortality of the soul, an undigestible book; and the prose lyrical idyll, *My Prospective Autobiography* (1799). *The Invisible Lodge* was his first literary success; *Hesperus* made him famous. In 1796 Charlotte von Kalb, perhaps the most remarkable, certainly the most advanced, woman of her age in Germany, wrote to express her admiration of the book; and a few months later, at her invitation, Jean Paul visited Weimar. There Goethe received him politely, but with cool reserve; that, too, was Schiller's attitude, when Jean Paul went on to Jena to see him. The antagonism between them was deep and fundamental, and lasted till death, being at times but ill concealed by all three. Herder and his wife, on the other hand, greeted the young romance-writer with overflowing admiration, and gave him their friendship, which also endured till death. As for Charlotte von Kalb, she did not stop at friendship: in spite of having a husband already, she exercised her sex's fabled privilege of leap-year—her first letter to him was dated 29th February—and gave him unmasked the love of her vehement heart.

From this time for a few years Jean Paul's life was rich in incident and full of excitement—an Odyssey of love adventures, in which he was the object of extravagant idolatry on the part of the women of Germany, especially of aristocratic dames who dabbled in literature. They gave him their love whether or no, and would have deserted husband and children for his sake; for, though not personally handsome, Jean Paul had a wonderful fascination of manner, particularly towards women. He found all women charming, he was a delightful talker and a good listener, and had a sweet and sympathetic smile—qualities that explain a good deal. In 1801 he married a Berlin lady, and three years later settled down at Bayreuth, attracted by its beauties of hill and valley, and by its beer. There he

spent the rest of his days, leading a simple, busy life, writing his books, playing with his children, tending his pet animals, and taking short summer journeys to different towns of Germany; the present of a flower filled him with perfect joy. His last years were clouded by the death of his only son, a promising student, in 1821, and by his own blindness. From 1799 he enjoyed a pension from the Prince-primate Dalberg, and then from the king of Bavaria. He died on 14th November 1825. The principal works of his married life were the two grand romances, *Titan* (1800-3; Eng. trans. 1862) and *Wild Oats* (1804-5; Eng. trans. as *Walt and Vult*, 1849), the former accounted by himself and by most German critics his masterpiece, though Englishmen would generally prefer the latter, as they would certainly prefer *Siebenkäs* to *Hesperus*; *Schmetzle's Journey to Plutz* (1809; Eng. trans. by Carlyle, 1827) and *Dr Kätzberger's Trip to the Spa* (1809), the best two of his satirico-humorous writings; the idyll *Fibel's Life* (1812); the fragment of another grand romance, *Nicholas Markgraf*; or *The Comet* (1820-22); a series of reflections on *Literature* (*Vorschule der Ästhetik*; improved ed. 1812), containing many excellent things about poetry, humour, wit, style; another series on *Education* (*Lernart*, 1807; Eng. trans. 1848, 1876, and 1887), a book that ranks with Rousseau's *Emile* as a standard work on training the young, and is full of evergreen wisdom; various patriotic writings (1808-12); and an unfinished *Autobiography* (1826), the finest of all his idylls.

Jean Paul stands apart entirely by himself in German literature, a humorist of the first water, a Titan, 'a colossal spirit, a lofty and original thinker, a genuine poet [in prose], a high-minded, true, and most amiable man. . . . He advances not with one faculty, but with a whole mind, with intellect, and pathos, and wit, and humour, and imagination, moving onward like a mighty host, motley, ponderous, irregular, inviolable. He is not airy, sparkling, and precise, but deep, billowy, and vast' (Carlyle). 'Two irreconcilable tendencies strive for mastery in him and his works—a dreary, lachrymose sentimentality, that shrank from the rough buffetings of life, and sought refuge in emotional dissipation, luxuriating in tears, caressing sorrow, coquetting with love, melting in melancholy longings for the world beyond the grave; and a sharp-eyed, wide-awake common sense, that saw workaday realities with the utmost clearness and discrimination. All his great qualities of imagination and intellect were, however, made ministers to his humour, which had the widest range, moving from the petty follies of individual men and the absurdities of social custom up to the paradoxes that are rooted in the permanent ordinances of the universe. He turns his irony—a tender, reverent, playful irony—upon all the relations of human life, even upon the holiest beliefs of his own heart. And, in spite of the egotism of genius that often shows itself so strongly in him, Jean Paul had the heart of a truly great and good man. Börne calls him the author *par excellence* of the lowly born, the poverty-stricken, the neglected, and the despised; to this class belong some of his finest characters, as Wuz, Fixlein, Siebenkäs, Vult. As a master of pathos he is put by De Quincey above Sterne. Few, if any, have written with such tender love and such delicate feeling of the idyllic joys of the country and the happiness of simple domestic life, particularly in the schoolhouse and parsonage. He had a wonderfully deep and sympathetic insight into the nature of woman, but has not created more than one lifelike woman (Lenette). Yet the male characters of his books, in so far as they are

humorous, are generally living beings, or else, if secondary characters, well-drawn pencil sketches in outline. Jean Paul is the classic author of friendships (Siebenkäs and Leibegeher, Walt and Vult); he matched them with his own friendship for Hermann and Oertel, and for Otto and the Jew Emmanuel Osmund. Nature was to him a living and divine presence: he loved her reverently, from the solemn stars to the tiniest flower, and his descriptions of nature embrace some of the loftiest hymns the spirit of man has chanted to the beauty and sublimity of created things—e.g. several passages in *Hesperus* and *Wild Oats*, the Dream of the Universe in *Siebenkäs*. God and the immortality of the soul were the great facts ever present to his mind, influencing all his thoughts. An enduring sense of the ethic worth of human action, 'a noble reverence for the spirit of all goodness forms the crown and glory of his culture' (Carlyle). The reason why he is so little known, except by name, is that of all great writers he is one of the most difficult to read, and it may be added to understand. No reader who has not the strongest constitution can struggle through the tangled thickets of encyclopaedic learning, the tortuous wit, the dreary wastes of digression and dullness, the hothouses of tropical sentimentality, amid which the gem-like gardens of his creative art are hidden. His prose is harder to translate than He idea, in mony, or restraint he has not the slightest respect. The principal idea in his (often) long sentences is too frequently lost amid a labyrinth of subordinate clauses. The story is chiefly a peg for Jean Paul to hang Jean Paul's self-communings and reflections upon, a *point d'appui* for the play of his wit and humour. The wildest improbabilities, the wildest extravagances of fancy, are indulged in without check. Sentence follows sentence teeming with allusions, analogies, images, metaphors, similes, tumbling one over another in inextricable confusion. A Cossack of idioms, he is the greatest and most prolific word-crafter in the language: he compels words to adapt themselves to his ideas. Often enough his diction is inflated and bombastic, and his literary taste execrable: yet when he is at his best his language marches with a majesty, a dignity, a natural beauty that are seldom matched in German literature. Carlyle's *Sartor Resartus* and *French Revolution* are steeped in the spirit of Jean Paul, and show how greatly he fascinated the imagination of the rugged Scotsman.

See *Wahrheit aus Jean Paul's Leben*, his Autobiography (1826), continued by Otto and Förster (1827-33); Spazier's *Biographischer Kommentar zu Jean Paul's Werken* (5 vols. 1833); Förster's *Denkwürdigkeiten* (4 vols. 1863); Correspondence between Jean Paul and Otto (4 vols. 1829-33), Charlotte von Kalb (1882), Jacobi (1828), and Voss (1833); two works by Nerlich (1876-89), and two by F. J. Schneider (1901-6); the Life by Friedrich Burschel (1925); also Carlyle's *Miscellaneous Essays* (vols. 1. and m.), De Quincey's *Andréa* (of specimen passages translated (vol. xi. of *Collected Works*), and *Life of Jean Paul F. Richter* (1845); and Stefan George's essay in *Tage und Taten*.

Richtshofen, FERDINAND, BARON VON, traveller and geographer, was born at Karlsbuh in Silesia, on 5th May 1833, was educated at Breslau and Berlin universities, and at the Geological Institute of Vienna (1856), and in 1860 accompanied a Prussian expedition to eastern Asia. The next twelve years he spent in travelling through Java, Siam, Burma, California, Sierra Nevada, and China and Japan (1868-72). After his return to Europe (1872) he was appointed president of the Berlin Geographical Society (1873-78), professor of Geology at Bonn (1875), and of Geography at Leipzig (1883) and at Berlin (1886), and director of the Museum für Meereskunde in Berlin (1900). His reputation

as a geographer is built principally upon his great work on *China* (Berlin, 5 vols. and atlas 1877-1912), and upon *Die Metallproduktion Kaliforniens* (1865), *The Natural System of Volcanic Rocks* (San Francisco, 1867), *Aufgaben und Methoden der heutigen Geographic* (1883), and articles in geographical journals. He died 7th October 1905.

Ricinus. See CASTOR-OIL.

Rickets (etymology unknown), or **RACHITIS** (Dr Glisson's pseudo-Greek coinage in 1650 from Gr. *rhachis*, 'the spine,' because a peculiar form of spinal curvature results therefrom), is a disease of children, chiefly characterised by the imperfect development, softness, and consequent distortion of some or many of the bones. Though so soft, they are thickened, especially at the parts where growth normally takes place most rapidly; the enlargement of the wrists, ankles, &c. which results has led to the term 'double-jointed,' often applied to those suffering from the disease. The weight of the body and the traction of the muscles acting on bones thus constructed cause them to bend, and the thighs or shins are abnormally arched, or the spine is curved, or, in slighter cases, only the normal form of the ankle is modified. In aggravated cases the chest is so affected as to give rise to a deep groove low down in either side; the lower jaw is imperfectly developed, and the teeth project; the forehead is high or overhanging, and the pelvis becomes so altered in form as, in the case of girls, to render future child bearing in the highest degree perilous. Rickets is exclusively a disease of childhood, and rarely begins later than the second year. It appears to be caused by unhealthy surroundings, particularly defective or improper food, and insufficient light and air. It is therefore much more common among the poorer classes, and in towns. It is not due in most cases to the want of lime-salts in the food, but to the want of power in the child's system to assimilate them. This has been shown to be largely dependent on the insufficiency of suitable fresh food, especially of animal fats, which contain a vitamin (fat-soluble vitamin A) necessary for growth. In some of the large cities of Europe one-third or even a larger proportion of the children brought to the out-patient departments of hospitals are more or less affected. It is a very chronic disease, and if at all severe leaves its mark on the bones for life. It is very rarely fatal of itself; but affected children are much less able than others to resist attacks of other diseases (bronchitis, diarrhoea, hooping-cough, measles, &c.). In Germany this malady is, under an old misapprehension, called the 'English disease.'

The treatment must be mainly directed to the improvement of the general health. Free exposure to pure bracing air, sponging with sea-water, or sea-bathing if the little patient can bear it, an abundance of suitable and nourishing food, cod-liver oil, and, above all, fresh natural foods like milk, eggs, butter, and a little fresh fruit are requisite. The administration of lime-salts seems to do little good, though it might naturally be thought the one thing needful. While the bones are still soft great care must be taken to keep the child in such attitudes as will cause the least possible strain upon the affected parts. When the bones have become ossified in faulty positions surgical interference may often be useful in producing amelioration of the deformity.

Rickettsia Bodies. See GERM (THEORY OF DISEASE).

Rickman, THOMAS, an English architect, was born at Maidenhead in Berkshire in 1776. He was undecided as to a calling, being in succession chemist, grocer, corn-factor, and insurance agent.

But he seems to have always had a love for architecture, and to have studied it carefully. Having sent in a design for a church that proved successful in a government competition, he settled at Birmingham as an architect. He designed a great number of Gothic churches and chapels—e.g. in Birmingham, Hampton Lane, Bristol, Preston, Carlisle, &c., many country-houses, and the New Buildings of St John's College, Cambridge. He died in March 1841. His *Attempt to discriminate the Styles of Architecture in England from the Conquest to the Reformation* (1817; 6th ed. by J. H. Parker, 1862) became a standard authority.

Rickmansworth, a town of Hertfordshire, at the confluence of the Colne, Gade, and Chess, 4 miles W. by S. of Watford. It has a church (rebuilt in 1890) with interesting monuments; and near it is Moor Park, the seat of the ill-fated Duke of Monmouth, as its predecessor was the residence of Wolsey. Its garden was described as it appeared when it belonged to the Bedford family by Sir William Temple (q.v.), who called his own house at Farnham by the name of Moor Park. Pop. 7500.

Ricord, PHILIPPE, a French physician, was born on 10th December 1800, at Baltimore, U.S. He came to Paris in 1820, and after 1828 delivered there two annual courses of lectures at the Pitié on surgical operations, and was appointed surgeon-in-chief to the hospital for venereal diseases. This post he held till his retirement in October 1860. He died on 22d October 1889.

Riddles have been defined as 'roundabout definitions of the hearer has to guess what.' They were widely popular in dim antiquity, as to-day among many half-civilised races. They may be broadly divided into two classes—riddles admitting of solution, and riddles whose solution is beyond any wit of man, unless indeed, as is very often the case, the answer is known already. Of insoluble riddles Samson's is a good instance, and this which, in a Russian folk-tale, is put by 'Boots' to the princess: 'As I came to you I saw on the way what was bad, and I struck the bad with a bad thing, and of what was bad the bad died.' Naturally the princess could not guess that he had killed a snake with his lance; she gave it up, and had to marry him. Such propounding of riddles for wagers (her hand to his head in this instance) meets us frequently—e.g. in the ballad of 'Prond Lady Margaret,' 'Captain Wedderburn,' and 'The Elfín Knight.'

The riddle is found in the Koran, and several collections of riddles exist in Arabic and Persian. They were, it seems, also known to the ancient Egyptians, while among the Greeks they were alluded to in the earliest times with the oracular responses, and were generally in poetical form. But in Greece they first came into vogue about the time of the 'Seven Sages,' one of whom, Cleobolus, was celebrated for the composition of metrical *griphoi*. Even the greater poets did not disdain to introduce them into their writings, or to devote whole poems to the subject—e.g. the *Symna*, commonly ascribed to Theocritus. Apuleius wrote a *Liber Ludicrorum et Griphorum*, but it is lost; and almost the only name we can fix upon is a certain Caius Firmianus Symposius, whose riddles, comprising a hundred hexameter triplets, are termed by St Aldhelm 'rubbish' ('carmina inepta'). Some of the English riddles (probably 8th century) in the Exeter Book rise to the level of literature.

The riddle was much cultivated during the middle ages. Many French, English, and German riddle-books exist in MS., and some were printed at an early period. Wynkyn de Worde's *De-maundes Joyous* (1511) contains several that are simply coarse jests; but others, again, well illus-

trate the simple faith of mediæval Christendom—e.g. '*Demand*: What bare the best burden that ever was borne? *Response*: The ass that carried our Lady when she fled with our Lord into Egypt.' The Reformation checked riddle-making; but in France, in the 17th century, it began to creep back into favour. Le Père Menestrier, in 1694, wrote a grave treatise on the subject; and before that, in 1646, the Abbé Cotin had published a *recueil*, in the preface to which he modestly dubbed himself 'le Père de l'Enigme.' 'Posterity,' adds a French critic, 'has not recognised his paternity.' The taste grew and grew, and many brilliant French writers, such as Boileau, Voltaire, Madame du Deffand, and Rousseau, did a little in this line, until finally the *Mercure de France* became a fortnightly repository of riddles, the solution of which secured a reputation in society. In Germany we have Schiller's delightful extravaganzas, *Turandot*; and in England Cowper, Fox, Canning, and Præd are a few of the makers of poetical riddles on Charnades (q.v.).

See chap. iii. of Tylor's *Primitive Culture* (1871); Ralston's *Songs of the Russian People* (1872); Friedreich's *Geschichte des Räthels* (1869); Rolland's *Devinettes ou Énigmes Populaires*, with a preface by Gaston Paris (1877) and a bibliography; and for Old English riddles, Stopford Brooke's *Early English Literature* (vol. i. 1892); Tupper, *Riddles of the Exeter Book* (Boston, 1910); Wyatt, *Old English Riddles* (Boston, 1912).

Ridge, WILLIAM PETT, born in 1864 at Chart ham near Canterbury, began to write stories and novels in 1890 (amongst them *A Clever Wife*, *Mord En'ly*, *Name of Garland*), and is best known as an exponent of cockney humour.

Ridgway, ROBERT, born in 1850 at Mount Carmel, Illinois, in 1880 was made curator of the birds division of the National Museum at Washington. He has written numerous works on American birds, notably *The Birds of North and Middle America* (8 vols. 1901 et seq.).

Riding. The two objects aimed at in *ordinary riding* (which includes riding on the road, hunting, pig-sticking, stock driving, breaking in young and freshly handled horses, playing polo, race and steeplechase riding) are to remain in the saddle and to make the animal carry its rider with the greatest possible ease to itself. The former of these objects is the one almost entirely aimed at by the breaker when giving his first lessons; the latter, by the flat-race jockey. Hence we find that the saddle and seat adopted by the Colonial buck-jumping rider are those that are best suited for 'sticking on.' The large pads on the flaps of his saddle are about six inches deep, and are curved backward, so as to fit against his thighs, a little above the knees. The seat of the jockey, instead of being that in which most security can be obtained, is the one by which the rider can best conform to the movements of his mount. Hence we find that, even in Australia, many of the best jockeys on the flat are but very poor performers on a buck-jumper. In all kinds of riding balance rather than grip should be the chief means for retaining one's seat in the saddle, for if muscular action be constantly employed to 'stick on' the muscles then brought into play will soon become tired, and will be unable to act at the very moment their aid is most required. One valuable rule in riding is that, except when applying the leg to the animal's side, the leg from the knee down should remain unaltered in its position, so that neither knee nor foot will work backwards or forwards. The movements of the upper part of the body should be regulated by the play of the hips. There should be no hollowing out of the small of the back or pushing out of the chest, or any other action which would give rigidity to the muscles. The rider should endeavour to avoid

the two very common faults of holding on by the reins and of putting too much weight on the stirrups, and he should try to ride with his seat well under him and not stuck out behind. If he find that he is insecure in his saddle he should allow no false shame to prevent him from getting one in which he will have a firmer hold. To give this additional grip the saddle may be covered with buckskin, or with leather the rough side of which is put on the outside. The saddle should be roomy. The back part, upon which the seat rests, should be fairly flat; the seat ought to have a good 'dip' in it; and there should be tolerably large 'rolls' on the flaps. To become a good rider one will require plenty of practice, and a frequent change of horse and saddle. The English style of riding is that adopted in the hunting-field, race-course, steeplechase-course, and polo-ground.

In *school riding* the object of getting the horse to carry his rider with the greatest possible ease to himself, which is the chief aim of the ordinary rider, is sacrificed to a large extent for increased control, so as to get the horse to perform the various *airs de manege* with precision. The English military riding system is a kind of compromise between that of the Continental *haute école* and the English hunting style.

In *side-saddle riding* the lady depends for security of seat on balance and on the grip she has on the upper and lower crutches. Her right leg is placed over the former, and she presses her left leg, a little above the knee, against the latter when she seeks their aid. Her left foot should not be placed 'home' in the stirrup, but only as far as the ball of the foot; and the heel should be slightly depressed. If, when her left leg is held in this manner, she can just feel the pressure of the lower crutch, the length of her stirrup will be about right. The only pace at which she should put weight on the stirrup is the trot. The great requisite for obtaining a 'square' seat, which is the one correct position, is to put the weight on the right leg, and not equally on both, as is often wrongly advised, and to bring the left shoulder up as much as the right. The body should be free from all stiffness, and should be kept erect by the play of the hip-joints, and not by hollowing out the small of the back and pushing out the chest. The rider should try to get her seat well under her. The side saddle for ladies was introduced into England about 1382 by Anne of Bohemia, and almost disappeared early in the 20th century.

Ridinghood, LITTLE RED. See PEIRAUULT.

Ridings originally *thrithings* or *thridings*—are ancient divisions of counties, now practically known only in Yorkshire; the initial consonant of the Old English word having been absorbed by the *t* or *th* of the preceding *west*, *east*, *north*. The word also appears as *trithing*, *trading*, *trading*, and in many other spellings. According to the (so-called) 'laws of Edward the Confessor,' the *trading* was the third part of a province, and to its court were brought questions that could not be settled in the court of the wapentake. There were three ridings of Lindsey in Lincolnshire (north, south, and west). There were at one time ridings in Tipperary, as also in Ontario and in Long Island, New York. Under the Local Government Act of 1888, each of the Yorkshire ridings is a separate administrative county. See YORKSHIRE, COUNTY.

Ridley, NICHOLAS, Protestant martyr, was born about 1500, of good Northumbrian stock. From the grammar-school of Newcastle-upon-Tyne he passed to Pembroke Hall, Cambridge, became fellow in 1524, and master in 1540. The spirit of the Reformation had already begun to penetrate both universities; Tyndale and Bilney had taught

the new doctrines at Cambridge, and Ridley, no less than Crammer and Latimer, Cambridge students about the same period, had early caught something of their spirit. Ridley went next to Paris and to Louvain, and, having encountered some of the most active Reformers abroad, after a three years' absence returned firmly grounded in the new doctrines. He was made proctor to the university of Cambridge in 1533, became domestic chaplain to Crammer, afterwards to the king, and had already been made vicar of Herne, canon, first of Canterbury, then of Westminster, and rector of Soham, when in 1547 he was raised to be Bishop of Rochester. An ardent and outspoken Reformer, yet without either bigotry or intolerance, he brought great learning and admirable preaching power to the cause, and quickly made himself one of the foremost leaders of the church. On the deprivation of Bonner, Bishop of London, in 1550, Ridley became his successor. In this high position he distinguished himself by his moderation, his learning, and his munificence, prompted Edward VI. to the foundation of Christ's, St Bartholomew's, and St Thomas' hospitals, and assisted Crammer in the preparation of the Forty-one Articles, afterwards reduced to thirty-nine. In 1552 he visited the Princess Mary at Hunsdon, but failed to shake her adherence to her mother's faith. Thereupon, after the death of Edward VI., he warmly espoused the cause of Lady Jane Grey, and at St Paul's Cross declared both Mary and Elizabeth to be illegitimate, July 16, 1553. As soon, however, as Mary was proclaimed he repaired to Framlingham to make his peace, but was coldly received, and soon stripped of his dignities and sent to the Tower. Once at least he attended mass, but his spirit soon returned to him. In March 1554 he was sent to Oxford, together with Latimer and Crammer, to be tried by a committee of convocation, and after a profitless disputation all three were adjudged defeated and obstinate heretics, and condemned to suffer at the stake. As England was not yet formally reconciled to Rome, the sentence could not be carried out, and accordingly Ridley lay in Bocardo gaol at Oxford for eighteen months, writing the while a noble and touching farewell letter to his friends. After the formality of a second trial he was led forth to execution, along with Latimer, 16th October 1555. The stake was placed in front of Balliol College, and here Ridley played the man in the midst of awful torments of a smoldering fire that burned him slowly to death. His writings were collected in a volume of the Parker Society series (1841), with a life by Rev. H. Christmas. See his life by Dr Gloucester Ridley (1763).

Rieka. See FIUME.

Riel. LOUIS, a Canadian insurgent, born in Manitoba in 1844, became a leader of the Métis, or French half-breeds, and headed the Red River rebellion in 1869-70, afterwards escaping from the country. In 1885 he again established a rebel government in Manitoba, and in November, the rising having been quelled, he was executed at Regina.

Riemann. KARL WILHELM JULIUS HUGO, German musical theorist and historian, was born 18th July 1849 at Sondershausen, and died at Leipzig, 10th July 1919. After a wide education in the arts and in music, he lectured on musical theory at Bromberg, Hamburg, Sondershausen, and Wiesbaden. He became professor at Leipzig (1901), director of the Musical College (1908), and head of the musical research institution in 1914. His writings are enormous in extent and in influence, and include text-books, histories, catechisms, &c., his *Handbuch der Musikgeschichte* the most notable.

Rienzi. COLA DI, the famous Roman tribune, was born at Rome in 1313. His parentage was humble, his father being a tavern-keeper named Lorenzo, by abbreviation, Rienzo; the family name of Gabrini is sometimes added. The son Nicolas (shortened into Cola) studied grammar and rhetoric, read and re-read the Latin historians, philosophers, and poets (Greek was scarcely yet known in Italy), and excited his imagination, while at the same time he coloured his speech, with the prophetic enthusiasm of the inspired writers. The assassination of his brother by a Roman noble, whom he found it impossible to bring to punishment, finally determined him to deliver the city from the barbarous thralldom of the barons. In 1343 he was appointed by the heads of the Guelph party spokesman of a deputation sent to the papal court at Avignon to beseech Clement VI. to return to Rome in order to protect the citizens from the tyranny of their noble oppressors. Here he obtained a favourable hearing from the pope, who appointed him notary to the civic chamber. In April 1344 Rienzi returned home, and sought to obtain the countenance of the magistrates in his ideas of reform; but reform he found was impossible without revolution; and for three years he loudly and openly menaced the nobles. At last, when Rienzi thought he could rely on the support of the citizens, he summoned them together on the 28th of May 1347, and, surrounded by 100 horsemen and the papal legate, he delivered a magnificent discourse, and proposed a series of laws for the better government of the community, which were unanimously approved of. The aristocratic senators were driven out of the city, and Rienzi, as tribune of the holy Roman republic, was invested with practically dictatorial power. The pope confirmed the eloquent dictator in his authority; all Italy rejoiced in his success, and foreign lands, even warlike France (according to his enthusiastic friend and admirer, Petrarch), began to dread the reviving majesty of the Eternal City. A bright dream flashed across Rienzi's imagination, the dream of every great Italian from Dante to Mazzini—the unity of Italy and the supremacy of Rome! Rienzi despatched messengers to the various Italian states, requesting them to send deputies to Rome to consult for the general interests of the peninsula, and to devise measures for its unification. These messengers were everywhere received with enthusiasm, and, on the 1st of August 1347, 200 deputies assembled in the Lateran Church. Rienzi was crowned tribune with great ceremony on the 15th April. But the nobles were still bitterly hostile; Rienzi, who defeated them in a bloody battle on the 20th November, became suddenly infected with the insolence of victory and power, and proceeded to levy taxes and enforce obedience. The papal authority was turned against him; after a short reign of seven months he lost heart at the combination of forces against him, and fled to Naples.

After two years of religious meditation among the mountains of the Abruzzi, Rienzi resumed his life as political reformer, and went to Prague to secure the support of the emperor, Charles IV. Charles, however, sent him as a prisoner to Pope Clement VI. to Avignon, but by the mediation of Petrarch he was released from imprisonment. A new pope, Innocent VI., resolved to take advantage of Rienzi's old popularity in order to crush the power of the Roman nobles, now becoming troublesome, and sent him to Rome in the train of Cardinal Albornoz. Their mission was swiftly accomplished, and the power of the nobles overthrown again. Rienzi aimed, however, at re-establishing himself in supreme authority. In August 1354,

having borrowed money and raised a small body of soldiers, he made a sort of triumphal entry into Rome, and was received with universal acclamations. But misfortune had impaired and debased his character; he abandoned himself to luxurious living, and his once generous sentiments had given place to a hard, mistrustful, and cruel disposition. The barons refused to recognise his government, and fortified themselves in their castles. The war against them necessitated the contraction of heavy expenses; the people grumbled; Rienzi only grew more severe and capricious in his exactions and punishments. He even murdered the free captain, Fra Monreale, for his wealth. In two months his rule had become intolerable, and on the 8th of October an infuriated crowd surrounded him in the Capitol, and put him to death with ferocious indignities.

The fortunes and fate of Rienzi have been made the subject of a romance by Lord Lytton, and of an opera by Wagner. See monographs on Rienzi by Papencordt (1841), Auria (1885), Rodeanachi (1888), Cosenza (1913), and D'Annunzio (1913; not critical); and the histories of Mediaeval Rome by Gregorovius and Rennout.

Riesa, a town of Saxony, on the left bank of the Elbe, has large ironworks and other factories, and is, thanks to its situation on a navigable river, spanned here by a fine bridge, and to its railway connections, a distributing centre for agricultural products, coal, wood, petrol, &c.; pop. 24,000.

Riesengebirge (i.e. 'Giant Mountains'), a mountain range separating Bohemia from Prussian Silesia. Seen from Silesia on the north they look like a gigantic wall of rock, pierced at places by deep ravines. On the south they fall away more gradually. The highest peak is the Schneekoppe (5260 feet), the loftiest mountain in this part of Europe. Granite and crystalline schists, especially mica-slate, are the principal rocks. There are only three passes: one in the east, with a railway, from Lundsbut in Silesia to Trautenau in Bohemia; one in the west, from Hirschberg to Reichenberg; and one in the middle, from Hirschberg to St Peter in the upper Elbe valley in Bohemia. These mountains are a favourite tourist resort of the Germans. They figure in popular legend as the home of the mountain spirit Růbezah (‘Number Nip’), called also ‘Herr Johannes,’ who rules the weather.

Riesi, a town of South Sicily, 10 miles NW. of Teramo, has sulphur-mines and makes wine and olive-oil; pop. 17,000.

Rieti (anc. *Reate*), a city of Central Italy, on the ancient Via Salaria, 40 miles NE. of Rome, is walled, and presents a mediæval appearance; it has a fine cathedral with a monument by Thorwaldsen; pop. 19,000. See Colasanti, *Rieti* (1911).

Rievaulx Abbey, situated 26 miles N. of York and 10 E. by N. of Thirsk, is a ruined edifice, Norman and Early English in style, originally built for the Cistercian order by Walter l'Espee in 1131. The ruins consist of the choir and transepts of the church, with a choir-arch 75 feet high, the refectory, and the gate-house. They occupy a beautiful site in the valley of the river Rye; ‘Rievaulx’ is but a Norman-French translation of ‘Rye vale.’ At the dissolution this was one of the richest foundations in Yorkshire.

Rif, **Er**, the coast districts of northern Morocco extending from Centa to the western frontier of Algiers, and forming a line of steep cliffs with few harbours. Its Berber inhabitants were formerly much addicted to savage piracy. In our own day their subjugation has strained the power of Spain and France. Their leader, Abd-el-Krim, president of the Rif republic, surrendered to the French in May 1926.

Rifle-bird (*Ptilorhis paradisæa*), one of the Birds of Paradise, occurring in the bush of Australia and New Guinea. The male is extraordinarily brilliant, velvety-black above with a purple gloss, with green head, throat, and median tail-feathers, and bronzy abdomen. The female is, as usual,

Rifle-bird (*Ptilorhis paradisæa*).

more soberly coloured. Another fine species, *P. magnifica*, has a stiff breast shield of green. The name Rifle-bird or Rifleman-bird is also applied to a tiny New Zealand bush-wren (*Acanthodactyla chloris*), which makes a bottle-shaped nest in holes in trees. For another Rifle-bird see HONEY-EATER.

Rifleman. See VOLUNTEERS AND TERRITORIAL FORCE; and for the bird so called (*Ptilorhis*), see RIFLE-BIRD.

Rifles are small arms with barrels spirally grooved internally; the name, like cognate German, Danish, and other words for grooving or for the weapon, being referred by the *New English Dictionary* to the Old French *rifler* or *riffler*, ‘to scratch, scrape.’ The object of rifling any weapon, whether cannon or small-arm, is to cause the projectile to rotate, and thus to impart steadiness to it in flight. It was first used in small-arms to rotate a spherical bullet, and much later on to rotate an elongated one and keep it point first; for the latter, if not rotated, will turn end over end in flight, and instead of maintaining its initial velocity much better than a spherical one, and shooting much more truly at any except the very shortest range, as it actually does, would be markedly inferior in both respects. The reasons why rotation gives a gyroscopic steadiness to a projectile and keeps an elongated one point first are somewhat abstruse, and cannot be dealt with here; but the reason why an elongated projectile maintains its velocity better than a spherical one of similar weight is readily shown. Let us assume a solid elongated projectile of a diameter of 3 inches, with a length of 12 inches—a very usual proportion of length to diameter—and with head struck with two diameters, as in fig. 1; a solid spherical projectile of similar weight would have a diameter of 5·17 inches, as in fig. 2. Now the ability of any projectile to retain the

Fig. 1. Fig. 2.

velocity which is impressed on it is directly proportional to its weight, and the force tending to bring it to rest is the resistance of the air, and this resistance varies approximately directly as the area of the greatest cross-section of a projectile. In the elongated projectile considered this is 7 sq. inches, and in the spherical one 21·1 sq. inches, while the weights are the same. The spherical projectile, therefore, is on this account alone only about one-third as efficient ballistically as the elongated one.

For other reasons it would be even more inferior. Since the sectional area of a projectile is proportional to the square of its diameter, a handy method of comparing the ballistic properties of two bullets is furnished by the ratios of their weights to the squares of their diameters $\frac{W}{D^2}$ where D is

the diameter of the projectile in inches and W its weight in pounds. Thus a bullet whose weight is 215 grains and diameter 0.3 inch is superior ballistically to one which has a weight of 250 grains and a diameter of 0.35 inch, *always assuming that the shape of the head is the same in both the bullets compared*. As will be shown hereafter, the shape of the head greatly affects the air resistance, and an altered form of head may counterbalance an indifferent $\frac{W}{D^2}$. These points are fundamental in

the consideration of all ballistic questions.

The cause of the inaccuracy of smooth-bores was the necessity, especially in military arms, for allowing a clearance ('windage') between the bullet and the barrel to permit of easy loading, for, as the bullet passed up the bore on firing, it bumped from side to side of the bore, and its direction on leaving the muzzle depended on the chance position of the last bump.

The invention of rifling has been attributed to Gaspard Knoller, of Vienna, in the 15th century, and to Augustus Kottler, of Nuremberg, about 1520, and there is the evidence of many rifles dated before 1560 and still in existence—one of these, made in Hungary and dated 1547, being in the Rotunda Museum at Woolwich. Of course any of these may have been originally smooth-bores and rifled long subsequently to the dates on them or attributed to them, but it is very unlikely that all of them can have been thus treated; and after 1563 there is documentary evidence incontestably vouching for the existence of rifles. The genesis of the invention is variously ascribed to the practice of spinning a spear when throwing it; to the spiral feathering of arrows, which caused rotation; or to barrels, which were grooved with *straight* grooves to give a place for the fowling (which always proved a hindrance to loading) to lodge in, having been accidentally grooved spirally. This last idea seems now to be somewhat discredited. There is, however, no certain ground for any of the theories.

The rifle rapidly gained favour as a sporting arm, but the great objection to it for military use was the time taken in loading. The spherical ball had to be a tight fit to fill the grooves in the bore, and, apart from the friction due to fowling (in itself very considerable), had to be rammed down with great force, a mallet being sometimes employed to drive the ramrod down. Roughly speaking, it took about four times as long to load a rifle as to load a smooth-bore. As a result of this, although we hear of troops being armed occasionally with rifles as early as the beginning of the 17th century, and of some of the French cavalry regiments being supplied with a rifled carbine in 1680, these remain isolated instances, and no serious action was taken in the matter of introducing military rifles until towards the end of the 18th century, when it is unquestionable that the events of the American War of Independence (1775–81) brought the matter prominently forward, and it was never dropped again. The American soldiers were practically irregulars—a large number of them hunters and skilled in the use of the rifle—and their feats of shooting were often remarkable, for a time when the percentage of hits on firing with a musket at a target 100 feet by 6 feet at 75 yards was sixty, and only forty at 150 yards! (*Stray Military Papers*, Hime, London, 1897, page 29)—for accurate shooting at 400 yards has been recorded by a credible

witness. As a result, a corps of *Jagers*, armed with rifles, was recruited on the Continent and employed on the British side, and it may be said that the adoption of rifles into the British service dates from about 1800, when the 95th Regiment, afterwards the Rifle Brigade, was armed with the 'Baker' rifle, so named after the inventor. This weapon had a calibre of .620 inch, was sighted to 300 yards, and weighed about 9½ lb. The bullet was spherical, and was wrapped in a greased patch. The 'Baker' was superseded in 1835 by the 'Brunswick' rifle, which had a calibre of .704 inch and weighed about 11 lb. 5 oz. The Brunswick had two grooves only, and the bullet had a belt which fitted into them. The Baker rifle was most difficult to load after a few rounds, owing to fouling, and there was considerable trouble with the Brunswick on account of the bullet being wrapped in a greased patch, which rendered it difficult to fit the belt on the bullet into the grooves. It is probable that only the pence in Europe between 1815 and 1854, so far as Great Britain was concerned, rendered the retention of either of these rifles possible for so long. The Brunswick rifle was the first to have a percussion-lock instead of the old flint-lock. Percussion firing was generally adopted in 1842. The use of the ignition of detonating mixtures by percussion for firing small arms undoubtedly originated with the Rev. Alexander Forsyth, of Belhelvie, Aberdeenshire, in 1805; but the percussion-cup, as ultimately adopted, was worked out by others.

The advantage of the rifle, due to its accuracy, had now become established, and many efforts were made to overcome the difficulty in loading. These all took the form of a bullet which was a loose fit in the bore, and could be dropped into the barrel, where it rested, not on the powder charge, but on a ledge formed by a slight contraction of the bottom of the bore, or else on a pillar projecting up from the end of the bore round which the powder lay. The bullet, resting in either of these positions, was expanded into the grooves by blows with the ramrod. The first system was proposed by Captain Delvigne in 1826, and, modified by Colonel Poucharra in 1833 by the addition of a wooden 'sabot' or wad between the bullet and the powder, was adopted by France for some rifle regiments between 1838 and 1840. The second system, invented by Colonel Thonvenin about 1833, was not adopted by any Power. Neither system was taken up by Great Britain.

We now come to the introduction of the elongated bullet. Proposed as early as 1662, if not earlier, and actually tried by Benjamin Robins about 1740, by Captain Norton in 1823, and by Colonel Davidson (in India) in 1832, it was brought forward by W. W. Greener in 1835 in conjunction with a plug in the base, so that the bullet, easily loaded, might be expanded by the gases of explosion into the rifling. Delvigne in 1841 proposed one with a hollow base, apparently with much the same object, for the other and principal advantages to be obtained from an elongated bullet seem to have been but imperfectly appreciated at this time. About 1847 Captain Minié produced his

Fig. 3.

flat-based, elongated bullet (fig. 3), which was at first used in conjunction with Colonel Thonvenin's pillar for expansion; and finally, in 1849, a bullet with a hollow base and an iron cup in it (fig. 4), which was self-expanding. This bullet, modified,

and Captain Minié's rifle were adopted by the British, French, and Belgian governments in 1850-1851. Minié's bullet was not, however, the first elongated one used in the British service, for a certain number of Lancaster's rifles, with two large grooves forming an oval bore, were issued to the 1st Battalion of the Rifle Brigade for use in the Kaffir war (1846-52). The bullet for these had two wings fitting the grooves and a flat base, and shot fairly.

Fig. 4.

With the introduction of the Minié rifle, the important decision was come to in Great Britain, about 1852, to replace all the smooth-bores—which with the army, except 'rifle regiments,' was equipped—by rifles. The Minié rifle had a calibre of .702 inch, a bullet of 680 grains, a powder charge of 69 grains, was sighted to 1000 yards, and weighed about 9 lb. 13 oz. without, and 10 lb. 13 oz. with, bayonet. It was probably the best rifle in existence when adopted—apart from its being a muzzle-loader—but it was heavy; and as early as 1852 experiments to obtain a better had been undertaken at Enfield, with the result that the 'Enfield' rifle was approved for adoption in 1853, and many were issued in 1855 to the troops in the Crimea. In this rifle there was a considerable reduction of calibre—viz. to .577 inch. The bullet weighed 530 grains, but the powder charge was 69 grains, as in the Minié, and as a result a much higher velocity was obtained with it. It was sighted to 900 yards, and weighed about 8 lb. 14 oz. without, and 9 lb. 11 oz. with, bayonet. A shortened pattern was subsequently issued to rifle regiments, and a carbine, very similar to the short pattern, to the artillery and cavalry. The Enfield was issued to the native troops in India shortly before 1857, and suspicion of the grease on the bullets (which was believed by the Hindoo to be made of cows' fat, and by the Mohammedan of pigs' fat, and therefore an abomination to both) was alleged to be one of the proximate causes of the Indian Mutiny. The Enfield rifle, it may be added, whether converted to breech-loading on the Snider plan or unchanged, was an excellent weapon for its time, and remained the British arm until the adoption of the Martini-Henry rifle in 1871.

It is now necessary to revert to an earlier period in order to deal with the important subject of breech-loading. Breech-loading is very nearly contemporaneous with the introduction of firearms (q.v.), and many early weapons were so made; but the method was dropped, even for small arms, about 1600, owing to the inability to seal the escape of gas as gunpowder improved and pressures grew greater. Constant efforts were made to reintroduce it in small arms, and Robins speaks of a method in existence about 1740. Present in this as he was over the advantages of rifling, he says that breech-loading, 'though not in the manner now practised, would be of all others the most perfect for the construction of these sorts of (rifled) barrels,' for obviously breech-loading would get over all loading difficulties and the provision of expanding bullets. In this matter Prussia led all nations, and between 1841 and 1848 discarded the smooth-bore musket, and rearméd her forces with the celebrated 'needle-gun.' This weapon had a bolt-action very similar to those of the latest arms, to be described later; but instead of the metal cartridge, one of paper and of very peculiar construction, and containing both the powder and bullet. The latter was egg-shaped, with the rear part tapering off on finer lines than the front, and only .53 inch in diameter, whereas the bore was .607 inch in diameter. In order, therefore, that the bullet might be rotated, it was firmly embedded

in a papier-mâché plug, which fitted tightly in the bore and took rotation from the rifling. On the base of the bullet there was a patch of detonating composition, and the striker-needle, when the trigger was pulled, perforated the powder charge and struck this detonating patch, thus firing the cartridge. The rifle weighed, without bayonet, about 10 lb. 4 oz., had a bullet of 478 grains and a muzzle velocity of 1000 ft.-seconds, and was sighted to 656 yards (800 paces). It was not by any means a perfect arm; the paper cartridge sealed the escape of gas indifferently, and the needles were apt to break; but it was an immense advance over any muzzle-loader, as it embodied a self-contained cartridge with its own means of ignition, whereas with contemporary arms caps had to be placed on the nipples for each discharge. This weapon, improved in various ways, served the Prussians and, later, the Germans through the wars of 1864, 1866, and 1870, until in 1871 an improved weapon, the Mauser, was adopted.

The special advance made by the self-contained cap, as in the needle-gun cartridge, does not seem to have been appreciated at first, for of the many breech-loaders brought forward at this time, 1850 to 1860 (Shap's, Terry's, Greeners', Westley-Richards's in Great Britain alone), all had nipples to be capped.

The result of the war of 1864 seems, however, to have brought home to all the Powers the advantages of the Prussian system, and by 1866 France had adopted the Chassepôt breech-loader, a bolt-action weapon of .434-inch calibre, with a paper cartridge, having a cap fixed in the base. On the face of the bolt was an india-rubber washer to check escape of gas. It had a bullet of 386 grains, a muzzle velocity of 1328 ft.-seconds, was sighted to 1312 yards (1200 metres), and weighed, without bayonet, 9 lb. 5 oz. England in 1867, after a number of trials, adopted the Snider system, largely because the existing stock of Enfield rifles could be rapidly converted to it, as it was recognised that a better pattern was desirable; and a committee was appointed in 1866 to go into the question of the adoption of a new rifle, with the result that in 1871 the Martini-Henry was adopted. With the Snider was introduced a metallic cartridge—complete with bullet, charge, and cap—and with this cartridge the rifle shot about as well as the Enfield from which it was converted, and was quite efficient. Indeed, its metal cartridge-case put it well above both the needle-gun and Chassepôt. The breech-block was attached to a hinge running parallel with the barrel, and opened sideways and upwards. The striker passed diagonally through the block to the cap, and was struck externally by the hammer, which was part of the old rifle.

The Martini-Henry—a combination of the Henry barrel and Martini action—had a calibre of .45 inch, a bullet of 480 grains, and a muzzle velocity of 1350 ft.-seconds. It weighed 9 lb. without, and 9 lb. 12 oz. with, bayonet. It was a good rifle, but it is very doubtful whether it represented the best that might have been adopted at the time. Certainly in one respect—its extraction—it was decidedly weak. Its rifling (see fig. 5)

Fig. 5.

was peculiar, forming really a heptagonal bore with projections (B) at the junctions of the faces (A) of the heptagon. It was only a modification of Whitworth's hexagonal bore, which, for match-shooting

purposes, had carried all before it from 1857 to 1865, though unsuited for a military small-arm. The action of this rifle works as follows (see fig. 6): The breech is closed by the block (B) pivoted at P. Gearing with the back of the block (B)—in a manner which does not appear in the

Fig. 6.

figure—is a lever (L) pivoted at A, so that if the lever be pushed outwards in the direction of the arrow the front of the block falls and uncovers the breech, and if it be pressed back the block rises and closes the breech. When the block (B) falls its lower edge strikes the lower arm of the double-armed extractor (E), which is pivoted at P. The upper arm of the extractor (only partially shown) is forked, and the cartridge lies between the prongs, with its rim in rear of them. When, therefore, the lower arm is pressed down by the block, the fork moves backwards and extracts the cartridge. Taking the position in the figure, if the trigger (T) be pressed its sear leaves the notch (G) on the lower arm of the double-armed tumbler, also pivoted at A. This permits the compressed spring (N) to drive the striker (S), which is held back by the nose (C) of the upper arm of the tumbler, on to the cap of the cartridge. The action of opening the breech forces the tumbler back into the cocked position, withdraws the striker (S), and compresses the spring (N) ready for firing again.

At about the same time that Great Britain decided on the Martini-Henry, other Powers were in the main adopting bolt-action rifles of a type similar to the needle-gun and Chassepôt, but with cartridges with metal cases. Before, however, passing to the rifle of the present day, it will be well to consider more fully one or two features of the rifles which have been mentioned.

First, as to the grooves and twist of rifling. It is practically certain that the number and form of grooves in the early rifles were chosen by makers quite empirically and with no certain notion of what the rifling actually did; indeed, it was considered by some that it was the air passing over the inclined grooves on the bullet which caused the latter to rotate! Their number varied generally between six and eight, and their forms between rounded, sharp-cornered, notch-shaped, ratchet-form, shallow, and deep. As to twist, examples of both increasing and decreasing twists are found, and even of combinations of both—the last probably due to defective workmanship. The twist was usually slow, one turn in 47 calibres being about the quickest, the Enfield rifle of 1855 having a twist as low as one turn in 135 calibres. No doubt a slow twist was enforced by the small hold in the grooves of a spherical bullet, and the danger of 'stripping'—i.e. the bullet being forced through the barrel without turning, and the lead in the grooves being torn off—if a more rapid one were used; but with the elongated bullet the hold of the grooves is wider, and with velocities of less than 1500 ft.-seconds a twist up to one turn in 30 calibres is

quite feasible. If the velocity be increased above this, as in modern rifles, the lead, even if hardened with about 1 part of tin to 12 of lead, will not stand the rapid stress put on it, and the bullet must be sheathed with a stronger metal, such as cupronickel or mild steel. Professor Sir A. G. Greenhill, F.R.S., has provided a formula whereby the twist required to keep projectiles of various lengths steady in flight can be calculated, and the theoretical twists accord well with those found satisfactory in practice. The depth of the rifling also was based on no principle, and the grooving was unnecessarily deep and caused quite needless friction, especially with elongated bullets. The needle-gun had grooves .03 inch in depth, and most of the rifles introduced between 1841 and 1870 had grooves over .01 inch in depth. Metford, to whom many of the improvements in rifles are due, showed in 1865 that excellent results could be obtained with grooves only .004 inch in depth, and the depths of grooves in the latest rifles, with their very high velocities, rarely exceed .0065 inch.

As to sighting, the smooth-bore musket had only a fore-sight and no back-sight, and aim was taken roughly along the barrel. Back-sights came in with the Baker rifle, which was sighted to 300 yards with flap back-sights. The Lancaster rifle, sighted to 900 yards, was the first to have the back-sight with folding leaf and slide, such as is used, though much modified, at the present time.

The comparatively poor ballistic properties of the Martini-Henry—it was outclassed by several foreign arms adopted about the same time—were recognised after a time, and a committee was assembled in 1883 to consider an improved pattern, and in 1886 recommended the Martini-Enfield rifle. This rifle had a bore of .402 inch, rifled with seven segmental grooves of the Metford pattern. It had a charge of 85 grains, a bullet of 380 grains weight, and a muzzle velocity of 1570 ft.-seconds. This rifle, owing to its higher velocity and an increase in the leverage for extraction, was an improvement

on the Martini-Henry, though its ^W₁₂ showed no improvement. A number of these rifles were made, but there was no regular issue of them to the troops, as three advances in rifle armament had taken place about this time—viz. the adoption of magazine arms by several Powers between 1878 and 1884, of a smokeless powder by France in 1886, and by the same Power at the same date of a rifle with a bore only .315 inch in diameter, the rifle of the previous breech-loading period having had calibres well over .4 inch, and it was clear that much more was needed in a new rifle than was provided by the Martini-Enfield.

To deal first with the question of magazine arms: the great importance of a magazine arm was first practically demonstrated in the American war between the North and South in 1861, when one regiment of the Northern army, armed with a magazine rifle, successfully resisted the attack of a force at least three times as numerous armed with the ordinary single-loader, simply on account of the great rapidity of fire. And again, in the war between Turkey and Russia in 1877, the constant repulse of the Russian assaults on the Turkish lines before Plevna was in a great measure, if not mainly, due to the fact that the Turks were armed with the Winchester repeating rifle, which enabled them to mow down the Russians by hundreds as they crossed the open to the assault. In the United States there were at that time several systems already in practical use, and after the

experience of the Turkish war the question was seriously taken up by most of the European governments. By the end of the year 1879 the French government had adopted the Kropatschek magazine rifle for the navy; the Germans were experimenting with a Mauser rifle converted to take the Lee magazine; the Austrians were experimenting with the Kropatschek and the Spitalzki; in Italy the Bertoldo rifle had been issued to some few regiments for trial; in Switzerland the troops were armed with the Vetterli repeater; and in Norway and Sweden a repeater on the German principle was on trial.

There have been many patterns of magazines for rifles, but of those which have been adopted all can be placed in one or other of two groups—viz. the *tube* magazine, in the butt or under the barrel, in which the cartridges lie nose to base and are pressed forward or backward by a spring; or the *box* magazine, lying just behind and below the breech, in which the cartridges lie parallel to each other, vertically or horizontally, and are fed upwards or sideways by a spring. The tube magazines were earliest adopted, and were invented in America; the Spencer about 1860, with a tube magazine in the butt; and the Winchester about 1867, with one under the barrel. Both of these have falling block-actions, for which the tube magazines alone are readily rendered suitable. The Fawcith (of which the Lebel and others are only slight variants) is the type of the tube-action for the bolt-action rifles. Of box magazines there has been only one example of those in which the cartridges lie horizontally and side by side—viz. the Krag-Jorgensen, with which the United States were, and Denmark still is, armed. The vertical box, either fixed or detachable, is that commonly used at the present time.

Comparing tube and box magazines, the former have the disadvantages that the emptying of the tube under the barrel alters the balance of the rifle; that the placing of the points of the bullets against the cap in the base of the cartridges in front is not devoid of danger, and accidental explosions have resulted from it; and, lastly, that the tube does not lend itself to any system of rapid charging. As a result the tube magazine is only used now by the army of one Power—France; and it is certain that she will not perpetuate the principle in any rearmament, as her cavalry already have a carbine with a box magazine. It may be added that no nation has ever adopted a tube magazine in the butt as in the Spencer rifle, owing, no doubt, to its unsuitability for combination with a bolt-action.

Smokeless powders are discussed under GUN-COTTON, and it is only necessary to say here that the advantage of these powders in their much greater power, in addition to their smokelessness, was soon appreciated.

Lastly, as to the smaller bore. The credit for this change appears to rest with Major Rubin of the Swiss ammunition factory at Thun, who brought forward a .295 rifle in 1883; but there is little doubt that the conviction was general that in order to reap the full advantage of the magazine the soldier should be able to carry more ammunition; and in addition to this, the lighter bullet could be propelled at a much higher velocity, as soon as the difficulty of 'stripping' was overcome, by introducing the enveloped bullet already referred to.

These new developments were considered in Great Britain by various committees, and in January 1888 a .303-inch rifle with the Lee bolt and magazine, and a barrel rifled with the Metford system of rifling, was recommended for trial, and the trials having proved satisfactory, the rifle, with several minor modifications, was approved for the service in December 1888. This rifle had a bullet with

cupro-nickel envelope weighing 215 grains, a charge of 70 grains of (black) gunpowder compressed into a pellet, and a muzzle velocity of 1850 ft.-seconds; weighed 9 lb. 8 oz. without, and 10 lb. 7 oz. with, bayonet; and was sighted from 200 to 2900 yards. [Unchanged in its main features, except as to its rifling, but with many improvements, it is substantially the rifle in the hands of the troops to-day. The alterations made are, briefly, the adoption of a somewhat simplified bolt, and the increase of the magazine to hold ten cartridges, instead of eight, in 1890; the adoption of 'cordite,' with an increase of velocity to 2060 ft.-seconds, in 1892; a new safety-catch and the alteration of the rifling in 1895; the adoption of a rifle for general use by both infantry and cavalry, 5 inches shorter and about half a pound lighter, with more delicate sighting arrangements allowing for small corrections in elevation and for wind; and the general adoption, both for new and old rifles, of the system of loading by 'charger' in 1902, and in 1907 some further improvements in the sighting and a better guide for the charger.]

As regards the alteration in rifling, the Metford rifling (see fig. 7), admirable for lead bullets, was found to wear badly with the bullet with cupro-nickel envelope; and the Enfield rifling (see fig. 8),

Fig. 7.

Fig. 8.

with slightly deeper grooves and much wider 'lands' (metal between the grooves), was found to stand much better, without any diminution in accuracy, even when both systems were tried comparatively in new barrels.

As regards 'charger' loading, the vertical box magazines lend themselves readily to being loaded rapidly by the insertion of a bundle of cartridges (usually five in number) side by side, held together in a 'clip' or 'charger.' The magazines of the Lee-Metford and Lee-Enfield rifles until 1902 were filled by putting in cartridges one at a time. The adoption of the latter system was no doubt based on the idea that with well-controlled infantry the use of the magazine would be exceptional, and that loading by single cartridges would be the rule; that loading by clip or charger would lead to waste of ammunition, while both chargers and clips add considerably to the weight of the ammunition to be carried. Accordingly the British rifle was provided with a magazine holding double the number of cartridges contained in the magazines of foreign rifles, and capable of being closed by a 'cut-off,' so that the rifle could, until emergency called for very rapid fire, be used as a single-loader. The experience of the South African war led, however, to the adoption of the Continental plan of loading by bundles of five cartridges, and the Lee-Enfield magazine being suited for 'charger' loading, this system was adopted. The difference between 'clip' and 'charger' loading is that the clip is used in a magazine with straight sides, and is inserted bodily with its load of five cartridges into the magazine,

where it is held by a catch, and the cartridges are pushed one by one out of the clip by the bolt in loading, and the clip when empty drops out of the bottom of the magazine; whereas the charger is placed in a guide over the magazine, and is thrown away after the cartridges in it have been pressed down out of it into the magazine, where they are retained, owing to the walls of the magazine being curved over at the top. This prevents the cartridges from being pushed out again vertically by the spring, which, in both systems, causes the cartridges to rise immediately there is a space left by a cartridge having been pushed into the breech. In both systems the top cartridge in the magazine lies with its base projecting into the path of the bolt when the latter has been fully withdrawn. In the British and a few other rifles a 'cut-off' is provided whereby the top cartridge can be pushed down and held clear of the bolt's path, so that the rifle can be used as a single-loader.

Fig. 9 shows a Maunlicher rifle-action with the clip and cartridges in the magazine, and fig. 10 a Mauser rifle with charger in place over the magazine ready for the cartridges to be pressed out of it into the magazine. Fig. 11 shows the Lee-Enfield action with magazine empty.

The working of a block-action for breech-closing in the case of the Martini-Henry has been explained, and an explanation of the essentials of a bolt-action will now be given. It should be noted that the same lettering is used for similar parts in figs. 9, 10, and 11.

Bolt-actions are of two kinds, the 'straight pull' and the turning. With the former the bolt lever or knob is pulled straight to the rear to open, and pushed straight to the front to close and lock, the breech. This is effected by the bolt being made in two or more parts, so arranged that the pushing or pulling of the rear part, to which the lever is attached, shall cause, by suitable cam-grooves, the part of the bolt carrying the locking-lugs (projections), by which the bolt as a whole is held firmly against the breech, to engage the lugs with, or disengage the lugs from, the locking recesses which are cut in the body attached to the barrel, or in the barrel itself. There are only three military rifles with this class of action—viz. the Austrian (Maunlicher), Swiss (Schmidt-Rubin), and the Ross rifle, with which the Canadian forces were armed up to 1916. It is very doubtful whether the small gun in time in not having to turn the bolt-lever in order to unlock or lock the bolt compensates for the increase in complication which is an undoubted feature of all straight pull actions. With turning bolts the locking-lugs are engaged with or disengaged from the locking recesses by simply turning the bolt-lever up or down.

As already stated, the earliest forms of breech-loaders depended for the sealing of the gases of explosion on the use of a paper cartridge-case, supplied,

of course, by the accurate fit of the bolt-head in the breech; and, in the case of the Chassepôt, by the use of an india-rubber washer squeezed out against the sides of the chamber. Great Britain was the first country to adopt the metal cartridge-case, and her example was soon followed by all other nations. It is not too much to say that without the metal cartridge-case the breech-loading small-arms of the present day, with their high gas pressures of, quite normally, 19 tons on the square inch, would be impossible. But the metal case necessitates a powerful system of extraction to remove it, when, after being fired, it fits tightly in the breech, owing to expansion by gas pressure. This is effected by an extractor, which is a spring claw lying by the side of and projecting slightly beyond the bolt-head. As the breech is closed, the claw rides up

Fig. 9.

Fig. 10.

Fig. 11.

over the base of the case and snaps over the rim, or into the extractor groove, of the case. As the bolt-lever is turned for opening, 'primary extraction' with considerable leverage is usually provided by one or both of the locking-lugs fitting in cam-shaped locking recesses, so that turning up the bolt-lever causes the bolt to be slightly withdrawn and the cartridge to be slightly shifted; after which, since all cartridges are slightly coned, it can be readily removed by pulling the bolt. The case is ejected by the part of its base opposite to that gripped by the extractor coming against a projection, which is brought into its path by suitable means just as the bolt has been nearly fully withdrawn. This causes the case to one side or upwards, according to the disposition of the parts chosen, and as withdrawal of the bolt is always done

sharply, it is thrown clear of the rifle (see fig. 12, which shows the ejection of the case from a Lee-Enfield rifle).

The way in which a fresh cartridge rises from the magazine ready to be pushed into the breech has been explained in discussing the action of clips and chargers.

Fig. 12.

The cocking of the striker and the compression of the striker-spring is effected as follows (see figs. 9, 10, and 11): The bolt slides in a bolt-way in the body of the rifle, and contains the striker and its spring. Attached to the rear end of the striker is the cocking-piece (A), a part of which (a) projects into a groove (B) in the bottom of the bolt-way. Projecting also into the groove (B) is the nose of the trigger-sear (C). When the bolt is pushed forward to close the breech, the projection (a) of the cocking-piece (A) encounters the sear-nose (C), and as a consequence the striker is held back, and the bolt being pushed forward and locked, the spring (D) is compressed between the rear face (E) of the hollow in the bolt and the collar (F) on the striker. This is the position shown in fig. 11. If now the trigger be pulled the sear-nose (C) is depressed, and the striker and cocking-piece, being no longer held back, are driven forward by the main-spring. Suitable means are provided to prevent the possibility of the rifle being fired before the bolt is locked, and safety-catches to render firing impossible if desired.

Fig. 13 shows the short Lee-Enfield rifle and bayonet with which the bulk of the British forces were armed during 1914-18. The rifle stood the test of war ex-

Fig. 13.

cellently in spite of two weak features which may be mentioned briefly. Its bolt differs from those of practically all other military rifles in that it has not its two locking lugs (projections) in front and engaging in recesses cut in the rear end of the barrel itself, but has them in rear of the centre of the bolt (longitudinally), and engaging, the one in a recess in, and the other against a projection on the side of, the boltway. Should the bearing of the lugs, owing to wear, not be quite even, the heavy pressure on the front of the bolt on firing causes a 'whip' of the bolt to one side or the other, as there is necessarily a little clearance between the bolt and the side of the boltway in which it travels and is housed. This 'whip' can, if bad, throw out the aim to some extent; and generally the design does not provide the strongest possible form of locking. Another feature which has been criticised is its small cartridge, limiting the possibility of increase of charge to get the highest possible velocity and flattest trajectory with a sharp-pointed bullet, as discussed later. As, however, the cartridge fulfilled excellently all that it was designed originally to do, and later on admitted of substantial increase in ballistics, it cannot perhaps fairly be described as a 'weak' feature. This latest development of the bullet is due to the action of France. In 1904, after considerable experiment, she adopted a bullet, with a very sharp point and tapered base (see figs. 14 and 15, which show her

old and new bullets respectively), made of an alloy of copper with 11 per cent. of zinc. This form of bullet is much less affected by air resistance, and this, coupled with a reduction in weight from 216 to 198 grains, and a consequent rise in velocity from 2073 ft.-seconds to 2380 ft.-seconds, led to the bullet's trajectory being very much flatter. Flatness of trajectory discounts considerably incorrect judgment of distances and errors in elevation generally; for, if the difference in height of trajectory for, say, 300 and 600 yards range be only 3 feet instead of 5 feet, it is clear that the chances of missing in the former case are much reduced as compared with the latter (see Sighting, Fig. 14. Fig. 15. under CANNON).

Fig. 14. Fig. 15.

All nations have adopted, or will adopt, the pointed bullet, but similar generally (apart from the aluminium filling at the point) to the British enveloped bullet (see CARTRIDGE), and not to the French solid design described above. The British bullet weighs 174 grains, and has a velocity of 2400 ft.-seconds, as compared with 215 grains and 2060 ft.-seconds with the pattern which was superseded in 1910. Although this improved bullet (the charge having been increased from 30 to 40 grains) gave a reduction in height of trajectory much the same as with the French bullet, the improvement was not considered sufficient, and in 1912 experiments were started to obtain a new rifle which would satisfy requirements. These experiments showed that—even with all the conditions of strength of rifle, a cartridge-case of ample size, and a bullet of the best ballistic design fully satisfied—the problem of getting the best possible com-

bination is far from simple, the immense heat due to firing the heavy charges needed to obtain velocities of 2900 ft.-seconds or more in a rifle of a reasonable weight—a fundamental condition—bringing about special difficulties. Consequently in 1914 re-armament had not commenced, and obviously had to be postponed, as the great changes in existing plant which would have been required were wholly impossible when immediate supplies of rifles and ammunition, on the largest possible scale, were essential. When placing, however, large orders for rifles in 1914 in the United States of America, where new plant had of necessity to be laid down in any case, the improvements introduced in the experimental rifle were adopted in the rifle, termed 'Pattern 1914,' ordered, except that it was designed to take the same cartridge as the short rifle, as the risk of mistakes in ammunition-supply in the field with two patterns of cartridge in use was far too great to run. When the United States joined the Allies in 1917, advantage was taken of the plant existing to manufacture this rifle, and it was adopted, with the small alteration required to suit the United States '300 cartridge, as 'Model 1917,' for their expeditionary forces. It is not, however, a certainty that the short rifle will be superseded in Great Britain by Pattern 1914.

As to future developments, there can be little doubt that the next step will be the replacement of the ordinary by automatic rifles, operated either

by gas or recoil as are Machine Guns (q.v.). Several already exist, and the Lewis machine gun, which played a great part in the war of 1914-18, is, as generally used, really a heavy automatic rifle. The advantage to be gained would not lie merely in being able to fire with great rapidity, but in ability to do so without the really great physical effort which the working of the bolt involves in long-continued rapid fire, even if, as can be done, the rifle is not brought down from the 'presented' position for loading. No doubt, to counterbalance the possible advantages, the waste of ammunition would often be prodigious, but it is quite certain that re-ammunition with an automatic rifle by any great power would force its general adoption. The moral effect on troops of being armed, or even thinking that they are armed, with an inferior arm is apt to be so disastrous that no nation could afford to risk it.

In 1883 the 'Morris' tube of 0.22-inch calibre, which could be fitted inside the barrel of the service rifle, and a miniature cartridge to be used with it, were introduced for short-range, or indoor, rifle practice. See MORRIS-TUBES.

The table which follows (based on that in the official text-book of small arms) gives the more important details of the rifles of the various nations; but, so far as the velocities given go, the period is one of transition, and, except in the case of Denmark, France, Germany, Great Britain, Japan, Russia, Spain, Switzerland, and the United States, who have already adopted the new form of light and sharp-pointed bullet, a considerable increase in muzzle velocity over the figures given in the table may be expected in the near future, but a velocity of about 2900 ft.-seconds will probably not be exceeded.

Country	Calibre in Inches and Designation	Weight with Mag. incl.		Weight without Mag. incl.		Weight Bullet	Muzzle Velocity (about)
		lb.	oz.	lb.	oz.	grains.	ft. sec.
Austria	.315 Mannlicher	9	0	8	5	244	2030
Belgium	.301 Mauser	9	10	8	0	219	2030
Denmark	.215 Krag-Jorgensen	10	1	9	12	196	2550
Great Britain and British Dominions	.303 Lee-Enfield	9	10	8	10	174	2440
France	.315 Lebel	10	1	9	3	198	2380
Germany	.311 Mauser	9	11	9	0	154	2900
Greenland	.226 Mannlicher-Schönauer	9	0	8	5	159	2230
Holland	.226 Mannlicher	10	7	9	11	162	2140
Italy	.256 Mannlicher-Carcano	9	3	8	6	163	2400
Japan	.256 'Yeat 38'	9	9	8	10	139	2500
Portugal	.226 Mauser-Vergero	9	9	8	13	155	2350
Russia	.256 Mannlicher	9	9	8	13	162	2400
Russia	3 'Three-line' Nagant	9	11	8	15	214	2850
Spain	.276 Mauser	10	5	9	6	173	2800
Switzerland	.226 Schmidt-Rubin	8	10	8	0	not known	
Turkey	.3 Mauser	10	8	9	1	212	2100
United States	.30 'Short Magazine'	9	8	8	8	150	2600

As to charging systems, all Mannlicher rifles (except the Greek rifle) use a clip, and all others the charger. All the magazine systems are box except that of France, and all magazines hold five cartridges, with the exception of Great Britain (ten) and Switzerland (six). The French tube magazine holds eight.

Rift Valley, a valley with steep parallel walls formed by a subsidence or vertical displacement of the earth's crust (see FAULT). Sometimes there is a single line of displacement along which the strata on one side have all been depressed. Frequently there are parallel faults dividing the strata into blocks, which show the effects of differential movement. The depressions thus caused may be

occupied by rivers or lakes, or both, and in time they tend to lose their characteristic sharp contours, so that in some cases they have assumed the appearance of ordinary erosion-valleys (see VALLEY). Rift valleys are not uncommon in mountainous countries in most parts of the world. The Upper Rhine marks one. A classical example is the gorge of the Jordan and the Dead Sea. The Yosemite is a characteristic type. The Great Basin (q.v.) in the United States shows many notable specimens, especially south-eastern Oregon. A great rift valley in South Australia, marked by Spencer Gulf and Lake Torrens, separates the South Australian highlands from Eyre Peninsula and the plateau of Western Australia. The East African plateau displays two great lines of depression. One is largely a subsidence of whole segments of the earth's crust. Of both, the lowest parts are occupied by great lakes. Southwards the two lines converge into one great valley occupied by Lake Nyasa, the southern part of this valley being less directly due to subsidence than the rest. Farther north, the western rift, the Central African trough or Albertine depression, contains a great succession of fresh-water lakes—Tanganyika, Kivu, Edward Lake, and Albert Lake. The Eastern African depression or rift valley contains Lake Rudolf and a number of smaller lakes, many of them brackish and without outlet. Volcanic peaks, obviously associated with the two depressions, occur on a line east of the eastern trough.

See H. R. Mill, *International Geography* (2d ed. 1900); J. W. Gregory, *Rift Valleys of East Africa* (1921).

Riga, capital of Lettland (Latvia), on the Dvina (crossed here by a bridge of boats and a railway bridge) 7 miles from its mouth, was till 1918 the third seaport of Russia. The old town has narrow streets and mediæval houses and stores; but the suburbs are laid out in broad streets with handsome buildings. The chief edifices are the (Lutheran) cathedral, built in 1204, burned down in 1547, but rebuilt; St Peter's Church (1406), with a steeple 460 feet high; the House of the Blackheads; the castle of the old Knights of the Sword (1494-1515), the former residence of the grand-master of the order; and several old guild houses and Hanseatic halls. The modern buildings include an Orthodox cathedral, an art museum, university buildings, schools, and a monument to Herder, who lived in Riga. It is the seat of an archbishop of the Greek Church, and a university (1919, till then a polytechnic). It manufactures cottons, machines, tobacco, corks, spirits, oil, metal wares, glass, paper, flax, jute, and oilcloth. Exports include flax, eggs, grain, timber; imports, machinery, rubber, coal, cotton, herrings, and tea. The port is kept open by ice-breakers in February and March. The town is accessible only to vessels up to 20 feet draught. Larger ships discharge at Ust-Dvinsk (Dünabünde) and Muhlgraben. Pop. 378,000. Nearly one-half of the inhabitants are Germans (with German-speaking Jews), and one-fourth Lets. Riga was founded in 1201 by Albert, Bishop of Livonia, and soon became a commercial town of the first rank, and member of the Hanseatic League. It belonged to Poland from 1561, in 1621 was taken by Gustavus Adolphus, and in 1710 was annexed to Russia. In September 1917 it was occupied by the Germans, and in October and November 1919 the German troops in the Russian service shelled it. Lettish independence was proclaimed at Riga in 1918, and there peace was made between Russia and Poland in 1920.

The GULF OF RIGA, an inlet on the east side of the Baltic, washes the shores of Lettland and Esthonia. It is 165 miles long, and about 60 broad. The Esthonian islands of Oesel, Dagö, Mohn, and Worms lie athwart the entrance. The chief river

which falls into it is the Dwina. Sandbanks render navigation in some parts dangerous.

Rigas. See RHIGAS.

Rigg. JAMES HARRISON (1821-1909), third in the Wesleyan roll of honour—after Wesley and Jabez Bunting—was born the son of a Wesleyan minister at Newcastle-on-Tyne, and entered the ministry in 1845. He was a member of the first London School Board, and was twice president of the Wesleyan Conference. He wrote on Wesley, the Wesleyan Church, and on theology generally, and edited the *London Quarterly Review*.

Righi. See RIGI.

Right. PETITION OF. See PETITION OF RIGHT.

Right Ascension. See ASCENSION.

Right-handedness is and has been the rule with men and women in all regions, amongst all races, and, so far as we can trace, at all past stages of human development. Amongst English-speaking adults, perhaps 97 per cent. show very much greater facility, dexterity, sensitiveness, and power in the use of the right hand. Very young children betray little disposition to use the right hand more than the left; but the habit, once established, is rapidly strengthened in childhood and youth. It is alleged that though the sickles of the Bronze Age were obviously made for right-handed people, the debated colths were chipped both for left-hand and for right-hand use. But though some of the cave-men's drawings suggest left-hand craftsmanship, the bulk of them are manifestly the work of right-handed people. Some allege that of every hundred children now born into the world, seventeen are from the first decidedly right-handed; three only are congenitally left-handed; perhaps eighty are either-handed persons, who with training might become ambidextrous or both-handed.

Right-handedness is a specialty of function, and must not be assumed as merely one aspect of the normal and organic asymmetry of the human body. But it should be remembered that though at first sight man seems to be built on symmetrical lines, in detail asymmetry is the general rule. In most people one eye is more powerful than the other, and one nostril is usually more sensitive. The ears are not shaped alike, are not equally acute, and are not placed equally far forward on the skull. The arms are usually of slightly different length and strength, and so are the legs. Very often the fingers of the two hands do not match perfectly. In these variations, sometimes the right has the advantage, sometimes the left; but there is one form of asymmetry in which the right always exceeds the left side. The viscera of the right side are distinctly heavier than those on the left side, the right lung being three-lobed, the left two-lobed. So with several other organs; and the arrangement of the blood-vessels has been treated as the main cause. Some have alleged that this is the actual cause of right-handedness; the greater weight on the left side leads to resting most on the right leg, and from that pillar of support we use the right arm with natural inevitable preference. But the question is not so simply settled. Some authorities deny that there is any organic or physical reason for right-handedness; refer it to instinct, to training, or to acquired habit due to the recognised convenience of uniformity of action amongst members of the same community. Some emphasise and some belittle the degree to which the preferential use of the right hand is transmitted by heredity. Right-handedness has been referred by some to the effect of nursing and infantile treatment; to the use of the left hand for defence of the heart in war, and of the right for striking; to the instruction of

seniors and the derisive criticism of eccentricity by comrades.

Of organic causes the lop-sidedness of the brain admittedly stands on a different footing from the other organic asymmetries. It is fully recognised that if the right limbs are acting most readily, the left side of the brain is doing more work than the right side. For nobody denies that the left hemisphere of the brain controls the right side of the body (see BRAIN). It used to be constantly alleged that the left cerebral hemisphere was larger and heavier than its counterpart, and that the convolutions of gray matter (the reservoirs of nervous energy) were more numerous on the left side than the right of the brain. But Professor D. J. Cunningham, in his Huxley Lecture (1902), emphatically denies this time-honoured view, and refers the belief in the greater weight of the left cerebral hemisphere to mere errors of observation. Braune has conclusively shown that if there is a difference in weight between the two hemispheres, it is the right that is the heavier, not the left; normally they are nearly of the same weight, and there is no evidence that the left is heavier in a right-handed person. Cunningham insists that our anthropoid ancestors were ambidextrous, like all monkeys, and that doubtless primitive man, while going on all-fours, was ambidextrous also. As soon as man began to walk on two feet, right-handedness asserted itself, feebly marked at first, but gradually gathering strength as the connection between hand and brain became more intimate, and as the work allotted to the hand grew in importance. He refers this human characteristic to the evolution of man by natural selection, and holds it to be due to left-brainedness, or the functional pre-eminence of the left brain—a superiority resting on 'some structural foundation,' which is transmitted from parent to offspring, but which has not yet been detected; for it is not, he is convinced, either the greater mass of the cerebral substance on the left side of the brain, or the multitude and arrangement of the convolutions. Mr E. S. Parson's theory is that man has for the sake of clearer sight departed from pure binocular vision; that partial one-eyedness brought one-handedness for co-ordination in aiming a blow; and that the necessity of defending the heart determined that the one should be the right.

See BRAIN; Sir Daniel Wilson, *The Right Hand* (1891); Lueddeckens, *Rechts- und Linkshändigkeit* (1905); D. J. Cunningham's Huxley Lecture to the Anthropological Society in 1902; Ewald Stier, *Linkshändigkeit* (1911); H. Maenaghten-Jones, *Ambidexterity* (1914), for a summary; Beaufort Stus Parsons, *Left-handedness; and Ambidexterity* (1905)—a plea for ambidextral culture by J. Jackson, founder of a society for that purpose.

Right Honourable. See ADDRESS (FORMS OF).

Right of Way, the right which the public has to the free passage over roads or tracks. The expression is more generally applied to those public routes which are *not* statutory roads, such as hill or field paths, drove roads, bridle and other paths, and cart or driving roads in the common use of the public, which are not kept up by the county authorities. In many instances these roads are the only means of communication between important districts; and generally they are the shorter, and often the more picturesque, ways from one point to another. Right of way also exists along the seashore and on the banks of tidal rivers. The law of rights of way is judicial and not statutory. In Scotland, where of late the chief *causes célèbres* have originated, forty years' continuous use by the public of such roads or paths is the prescriptive period for constituting a right of way; while in England the public acquire a right of way under

dedication to them by the owner of the soil, and user signifying their acceptance of the same, or when dedication can fairly be assumed from notorious user, which needs generally to be proved for a lengthened period, but which may yet, according to circumstances, be presumed from a period of user of only a few years. The following points fall under the legal aspect of a public right of way, according to the law of Scotland: (1) The path or road must go from one public place to another public place. By this is not meant that it must go from one town or village to another; it may be between any two points at which the public have a right to be, and to which they resort for some definite and intelligible purpose. Thus it may run from one highway to another; but it cannot run between a public road and a private house. (2) It must be along some tolerably well-defined route between the *termini*. (3) If there is a definite road between two public places it does not matter for what purpose it is used. It is not necessary that the public should use the road for any business purpose; it is quite sufficient if the purpose is merely for recreation, the exercise of walking, or the contemplation of the beauties of nature. (4) Its use must be maintained by the public themselves in order to keep up the right to the way. Continuous use is necessary, though the public need not use the road every day or every month; yet the right is in danger if use is discontinued for any length of time. But if the public allow themselves to be excluded from the road for seven years the proprietor becomes entitled to continue the exclusion by interdict without raising the question of public right—that is to say, possession for seven years throws the *onus probandi* on the public. According to the law of England such points are not construed in a narrow sense, and they distinctly differ in the following respects: (1) It is not necessary that the right of way be between two public places, and (2) continuous use is not necessary, for no lapse of time as regards user or the claiming of their rights can bar the right of the public to a footpath or a highway once dedicated to them, or where dedication can be assumed. There are, however, statutory provisions for shutting up a road when it becomes unnecessary. The whole breadth of the originally dedicated road, including what is known as 'road wastes,' must always remain as the right of way to the public, and cannot be encroached upon. See ROAD, TRUSTS.

In Scotland any member of the public, or, under the Local Government (Scotland) Act, 1894, a town council, a district committee, or a county council, may bring an action of declarator in the Court of Session for the maintenance of a public right. But 'what is everybody's business is nobody's business,' and many valuable rights have been lost. In England the Local Government (England) Act, 1888, enacts that county councils 'may, if they think fit, contribute towards the cost of the maintenance, repair, enlargement, and improvement of any highway or public footpath in the county, although the same is not a main road.

Rights, DECLARATION AND BILL OF. The Convention Parliament which called the Prince and Princess of Orange to the throne of England set forth, in a solemn instrument known by the name of the Declaration of Rights, the fundamental principles of the constitution which were to be imposed on William and Mary on their acceptance of the crown. This declaration (February 1689), drawn up by a committee of the Commons, and assented to by the Lords; began by declaring that King James II. had committed certain acts

contrary to the laws of the realm, and, having abdicated, had left the throne vacant. The main provisions of the Declaration, and of the Bill of Rights (October 1689) based upon it, were to the effect that the power of suspending and of dispensing with laws by regal authority is illegal; that the commission for creating the late Court of Commissioners for Ecclesiastical Causes, and all commissions and courts of the like nature, are illegal; that the levying of money for the use of the crown by prerogative, without grant of parliament, is illegal; that it is the right of the subjects to petition the king, and all prosecutions for such petitioning are illegal; that the raising or keeping of a standing army in time of peace, except with consent of parliament, is illegal; that Protestant subjects may have arms for their defence; that the election of members of parliament should be free; that freedom of speech in parliament should not be questioned in any place out of parliament; that excessive bail ought not to be required, or excessive fines imposed, or cruel or unusual punishments inflicted; that jurors should be duly empanelled, and that jurors in trials for high-treason should be freeholders; that grants and promises of fines and forfeitures before conviction are illegal; and that for redress of all grievances, and the amendment, strengthening, and preserving of the laws, parliaments ought to be held frequently. The remaining clauses treat of the succession to the crown.

Rights of Man, DECLARATION OF THE, a famous statement of the constitution and principles of civil society and government adopted by the French National Assembly in August 1789. In historical importance it may fairly be ranked with the English Bill of Rights and the American Declaration of Independence. It suggested the title for Paine's defence of the French Revolution against Burke (1791-92), which was followed by Mary Wollstonecraft Godwin's *Vindication of the Rights of Women*.

Rigi, or **Right,** an isolated mountain (5906 feet) between the lakes of Lucerne, Zug, and Lower, in Switzerland, is greatly frequented by visitors on account of the extensive views it commands of some of the finest Swiss scenery. Verdant pastures clothe the summit, and the slopes are belted with forests. Toothed railways ascend from Vitznau (1871) on the Lake of Lucerne, and Arth (1875) on the Lake of Zug. Near or at the summit are hotels, and a Capuchin monastery (1689), whose church contains a wonder-working image of the Madonna that attracts numerous pilgrims.

Rigidity is one of the properties of matter which sharply differentiate solids from fluids. In abstract dynamics a rigid system is a collection of particles which, however much they may move as a whole, never alter their mutual relative positions. Such a system has no true physical existence, since there is no known substance which can resist deformation. Nevertheless, those substances which yield but slightly to deforming stresses—all solids practically—are regarded as possessing a certain rigidity, which is measured by the ratio of the deforming stress to the deformation produced. The greater this ratio is, the more nearly does the substance approach the condition of the ideal *rigid* body. The property of rigidity itself, as described above, falls to be discussed under the general subject of elasticity. Of ordinary substances steel possesses the highest rigidity. See ELASTICITY, ETHER, MATTER.

Rigor Mortis. See DEATH.

Rigveda, the first and principal of the four Vedas (q.v.).

Rijeka. See FRUME.

Riley, JAMES WHITCOMB (1853-1916), 'the Hoosier poet,' born at Greenfield, Indiana, wrote in Middle West dialect. His poems about children are well known.

Rilievo. See RELIEF.

Rilke, RAINER MARIA, German poet, was born at Prague, 4th December 1875, of a Carinthian family. After studying at Prague, he spent most of his time in travel. For some years he was secretary to Rodin, on whom he wrote an excellent monograph (1903-8). His poetry—*Leben und Lieder*, *Traumgekrönt*, *Buch der Bilder*, *Stundenbuch*, *Neue Gedichte*, &c.—much influenced by Maeterlinck and the French Symbolists, is of a wistful, dream-like character, resting on a pantheistic mysticism. He also wrote plays and prose tales. See monographs by Scholz (1914) and Faesi (1920).

Rlio. See RHODOPE.

Rimbaud, JEAN NICOLAS ARTHUR (1854-91), a precocious French poet, precursor of the Symbolists, was born at Charleville, ran away from home repeatedly, lived as a tramp, fought in the Commune, associated with poets in Paris, travelled with Verlaine, who tried to murder him, wandered over Europe, deserted from the Dutch army in Java and took to the woods, had many other adventures, and finally became an Abyssinian gold and ivory trader, chief, and explorer, and died at Marseilles, whither he had gone to have a leg amputated. See Lives by Delahaye (1906) and Berriehon (1912); studies by Chaudel, Rivière, Delahaye, and Conlon.

Rimini, a city of Italy, stands on the shore of the Adriatic, 60 miles by rail S.E. of Bologna; it is still surrounded with walls, and contains many medieval buildings. The cathedral, the temple altered and built to commemorate the unhallowed love of Sigismondo Malatesta and Isotta degli Atti, a beautiful Renaissance structure, dates from 1446-50; the church of San Giuliano is adorned with pictures by Veronese, and San Giuliano with a picture of that saint by Gnerico. The ancient castle of the Malatesta is now used as a prison. The little river on which the city stands is spanned by a white stone Roman bridge, built by Tiberius, 236 feet long, with five arches. Beside one of the gates stands the triumphal arch, 46 feet high, erected in honour of Augustus. The spot (so tradition has it) where Caesar stood to address his soldiers after crossing the Rubicon (q.v.) is marked in one of the squares by a monumental pillar. The city manufactures silks and sailcloth. Pop. (1921) 19,996; with suburbs, 57,672. One of these suburbs, half a mile distant on the seashore, is much visited for sea-bathing. Originally an Umbrian, and then for several centuries an Etruscan city, Rimini (Ariminum) fell into the hands of the Romans in 286 B.C. They made it the northern terminus of the Flaminian Way from Rome, and the southern terminus of the Æmilian Way to Piacenza and of the Popilian Way to Venice, and utilised the advantages of its position as a seaport for communicating with the east side of the Adriatic. After being battled for by Goths and Byzantines, and held by the latter, the Lombards, and the Franks, it became a shuttlecock between the emperor and the pope. At last, weary of this alternation of masters, neither of whom profited her, Rimini put herself under the protection of the House of Malatesta (1237), whose chiefs soon made themselves absolute masters of her fortunes. Amongst the tragic episodes that marked the family history of these rulers may be mentioned the killing of Francesca (q.v.) da Rimini and her lover by his brother, and the death of Parisina, the subject of Byron's poem. The most famous, or rather infamous, member of

the family was Sigismondo (1417-68), a brave and skilful soldier, a scholar, a patron of the fine arts, but a man of brutal animal passions, and with no sense of right and wrong. The head of the house sold his rights over Rimini to the Venetians in 1503; but the pope wrested them to himself in 1528, and kept them until 1800. See Yriarte's *Un Condottiere au XV. Siècle: Rimini* (1882); Ricci, *Il Tempio Malatestiano* (Rome, 1925).

Rimsky-Korsakov, NICOLAS ANDREEVITCH, Russian musical composer, was born of well-to-do parents at Tikhvin, Novgorod, in 1844. He was destined for a naval career, and in 1865 produced his first symphony—also, the first symphony ever written by a Russian composer—when still a midshipman. It was only in 1873 that he definitely resigned from the navy, after being appointed Professor of Orchestration in the St Petersburg Conservatoire. He died at St Petersburg in 1908. His compositions comprise three symphonies, the symphonic suite, *Scheherazade* (1888), many beautiful songs and several operas, including *Night on May* (1878), *Snow Maiden* (1880), *Madra* (1892), *Sadko* (1896), *Tsar Saltan* (1900), *Invisible City of Kitesh* (1904), and *Cog d'Or* (1907). Rimsky-Korsakov is essentially a nationalist composer, his art being closely connected with Russian history, folk-song and folk-lore generally. His works are characterised by brilliant orchestration, especially in descriptive scenes, and by great lyrical expression. He edited the operas of Mussorgsky, produced an excellent Treatise on Orchestration (Eng. trans. 1922), and wrote an autobiography, *My Musical Life* (Eng. trans. 1924).

Rinderpest, CATTLE-PLAGUE, or BOVINE PEST, is a specific, contagious and infectious, eruptive fever, and the most serious and fatal epizootic disease to which the bovine race is liable. It is indigenous to the steppes and high tablelands of Central Asia, and never appears in Europe unless introduced directly or indirectly from the East. It affects ruminants, but is best known in cattle. It appeared several times in Britain during the 18th and 19th centuries, the last severe epizootic occurring in 1865-66. It was introduced by cattle from Reval, on the Gulf of Finland, which were landed at Hull on the 29th May 1865. They were spread over the country, at least to Leeds, Manchester, and London, and in a very short time the disease had extended as far north as Aberdeenshire, conveyed by calves from the neighbourhood of London. It spread rapidly, and the loss of cattle was enormous; never known exactly, it has been estimated at about 250,000. It was again introduced in July 1872 by cattle from Cronstadt, which were landed at Leith, Hull, and Deptford, and again in January 1877 by cattle from Hamburg which were landed at Hull and Deptford. On both occasions it spread to home cattle, but energetic measures were used and the disease was checked. Since May 1877 it has not been seen in Britain. It is very contagious, and its incubative stage is from three to eight days. No causal organism has been found; in fact, the virus passes through the finest filters. The symptoms are great depression, severe shiverings, twitching of the muscles, high fever—temperature often 105° to 108° F. There is often constipation at first, followed by profuse diarrhoea. An eruption appears in the mouth, on the udder in cows, and on the thinner parts of the skin. There is a discharge from eyes, nose, mouth, and in fact from all the natural orifices; often mourning; and the animal looks a pitiable object. The mortality is very high. In the 1865-66 outbreak it was estimated at 90-95 per cent. But in countries where the disease is indigenous it may be as low as 25 per cent. After death the principal lesions

are found in the alimentary tract. The fourth stomach, intensely inflamed, often contains circular or irregular patches of a deep claret colour with white lines between the patches. The bowels also may be acutely inflamed in streaks and patches with superficial ulcerations. Treatment is of little importance, except preventive—isolation, stamping out, and disinfection.

About 1889-90 the disease gained a footing in north-east Africa, and spread steadily south and west, killing off the ruminants in that continent, wild as well as domestic, and was still ravaging the cattle in South Africa at the time of the war. In 1897 Dr Koch, who had gone to East Africa to investigate the disease, found that by injecting a healthy animal with bile from an animal in the height of the fever an immunity was conferred, which lasted about four months. After long experimenting by various investigators, a method was elaborated by which a useful serum could be obtained from recovered or 'salted' animals. A veterinary conference held at Bloemfontein in December 1903 concluded that the best method of stamping out was a liberal use of serum, failing that, pure bile. A serum institute was established at Abbassieh by the Egyptian government at which serum was manufactured on a large scale.

Ring. Rings of gold, silver, and of other metals and materials have been worn in all times and countries, and while they have been used to decorate the ears, neck, nose, lips, arms, legs, and toes, finger-rings have always occupied the most important and significant place among such ornaments. From the earliest period of civilised relationships the finger-ring was a convenient means for carrying the signet of its wearer. In Genesis, xxxviii. 17, 18, we read that Judah left his signet as a pledge with his daughter-in-law; and in chap. xli. 42 it is narrated that Pharaoh delivered to Joseph his royal signet as a token of deputed power and authority. From the fact that these ancient rings carried engraved signets early ring-lore is intimately mixed up with the origin and development of gem and seal engraving. Herodotus mentions the wearing of finger-rings by the Babylonians; and from Asia the habit probably passed into Greece, although the Homeric poems mention ear-rings alone. In the later Greek legends the ancient heroes are described as wearing rings, and every freeman throughout Greece seems afterwards to have possessed one. The Lacedæmonians wore iron rings. Iron finger-rings were in use in Italy before the Iron Age began there—perhaps brought by Minoan traders. Every free Roman had a right to wear one;

and down to the close of the republic the iron ring was worn by those who affected the simplicity of old times. Ambassadors, in the early age of the republic, wore gold rings as a part of their official dress—a custom afterwards extended to senators, chief-magistrates, and in later times to the equites, who were said to enjoy the *jus annuli aurei*, from which other persons were excluded. It became customary for the emperors to confer the *jus annuli aurei* on whom they pleased, and the privilege grew gradually more and more extensive, till Justinian embraced within it all citizens of the empire whether *ingenii* or *libertini*. Rings entered into the groundwork of many oriental superstitions, as

Fig. 1.

in the legend of Solomon's ring, which, among its many magical virtues, enabled the monarch to triumph over all opponents, and daily to transport himself to the celestial spheres, where he learned the secrets of the universe. The Greeks mention various rings endowed with magic power, as that of Gyges, which rendered him invisible when its stone was turned inwards; and in old Saxon romances a similar ring legend is incorporated. The ring of Polycrates (q.v.), which was flung into the sea to propitiate Nemesis, was found by its owner inside a fish; and there were persons who made a lucrative traffic of selling charmed rings, worn for the most part by the lower classes. By many Mussulmans at the present day a ring having enclosed in it a verse from the Koran is worn as an amulet. Black coral rings are widely esteemed.

Various explanations have been given of the connection of the ring with marriage. It would appear that wedding-rings were worn by the Jews prior to Christian times. Fig. 1 shows a Jewish marriage-ring beautifully wrought in gold filigree, and richly enamelled. It has been said that as the delivery of the signet-ring to any one was a sign of deputed or sharing of authority, so the delivery of a ring by husband to wife indicated her admittance to share his rights and privileges. In pagan times in Europe the ring seems to have been connected with fidelity or with espousals. Fig. 2 shows a form of ring called a *gimmel*, or linked ring, which was used in later times; the upper fig. shows the three parts brought together, the lower fig. the parts separately. Ordinarily a

Fig. 2.

gimmel betrothal-ring was in two parts. By an ancient Norse custom, described in the *Eyrbryggja Saga*, when an oath was imposed, he by whom it was pledged passed his hand through a silver ring, sacred to that ceremony; and in Iceland the ceremony of betrothal used to be accompanied by the bridegroom passing his four fingers and thumb through a large ring, and in this manner receiving the hand of the bride, as is represented in a woodcut in an old edition of *Olafus Magnus*. As lately as 1780 the practice existed in Orkney of a man and woman plighting their faith at the Standing Stones of Stennis by joining their hands through the perforated Stone of Odin. For betrothal, as well as for marriage, a ring is commonly bestowed; and in many countries both spouses wear wedding-rings. Although the third finger of the left hand is the official finger, rings are worn on all fingers, and in mediæval times even the thumbs were frequently decorated with large and massive rings. During the 16th, 17th, and 18th centuries it was a very common practice to have mottoes inscribed on rings (fig. 3), including wedding rings, and the motto was called the *posy* or *chanson*. The ring was the symbol of the dominion of Venice over the Adriatic; and yearly,

on Ascension Day, a ring was thrown by the Doge from the ship *Bucentaur* into the sea, to denote that as the wife was subject to her husband, so was the Adriatic Sea to the republic of Venice.

Fig. 3.

The reception of a ring forms an essential feature in the investiture of many Catholic and Anglican dignitaries. The 'fisherman's ring,' containing an engraved representation of St Peter in an ancient fishing-boat, is the official ring of investiture of the pope. It is broken and remade on the death of each pontiff, and when presented to the new head of the church he declares the name under which he desires to rule, which name is thereafter engraved on it. Cardinals on their elevation receive a sapphire ring, and bishops on their consecration are also invested with a special ring. The reception of novices into Catholic sisterhoods is accompanied with the presentation of a ring, which is worn as a badge of espousal to the church. In the investiture of sovereigns the ring also occupies an important place in the coronation ceremonial. In addition to these, special rings were formerly worn by sergeants-at-law, who also on receiving silk made presents of rings to various functionaries (see *Notes and Queries*, 1884). Moreover, the knightly orders, masonic bodies, and merchants employed distinctive rings for enabling them to claim their privileges or facilitate their business. The carrying of seals attached to the watch-chain, and the introduction of gummed envelopes, had no small influence in decreasing the official importance of rings.

See the articles CRAMP RINGS, GEM; *Finger-ring Lore*, by W. Jones (1877), an elaborate compilation of the practices, superstitions, and traditions connected with rings. See also King's *Antique Gems and Rings* (1872); *History and Poetry of Finger-rings*, by C. Edwards (New York, 1880); articles by Waterton, Fortnum, and others in *Archæological Journal*, F. Schneider, *Die Gestaltung des Ringes vom Mittelalter bis in die Neuzeit* (Mainz, 1878); and G. F. Kunz, *Rings for the Finger* (1917).

Ring. See ASSOCIATIONS, TRUSTS, AND CARTELS.

Ringan. ST. See NINIAN.

Ringbones. This term is applied to osseous or bony growths which are found upon the pastern bones of the horse. They are of two kinds, true and false. The false ringbone is an exostosis situated about the middle of the long pastern bone, and as a rule gives no inconvenience, and unless very large is not looked upon as an unsoundness. The true ringbones, which are of two kinds—viz. high and low—are always to be considered as constituting an unsoundness of the gravest character, involving the articular ends of the bones, and giving rise to obstinate and often incurable lamenesses. The high ringbone involves the pastern joint, and the low ringbone the coffin joint, and is partly within the hoof; in many cases both high and low ringbones are coexistent. Ringbones vary in size, but the degree of lameness does not depend upon the mere size of the new formation. Very often the 'ring' may be a mere segment appearing only upon the side of the pastern; in other cases it may completely envelop the whole circumference. Ringbones are hereditary, and it is unwise to breed from an animal having a ringbone.

The treatment should be complete rest, fomentations and poultices at first, and afterwards blistering, firing; and in cases that do not give way to these remedies neutrectomy should be performed. A horse that is unable to work on the causeway or road may be able to work comfortably on the land.

Ring-dotterel, or RINGED PLOVER. See PLOVER.

Ring-dove. See PIGEON.

Ring Money. In early commerce, before the invention of coinage, but after the inconveniences of direct barter became evident, the precious metals in the form of rings and other personal ornaments were used as a medium of exchange. The employment of gold and silver as currency in this form among the early Egyptians is proved by contemporary wall-paintings showing the weighing of gold and silver rings, one such picture occurring in the decorations of a rock-grotto associated with the cartouche of Amenophis II. The allusion also in Genesis, xlii, 21, to the sons of Jacob finding their money 'in full weight' in the month of their sacks, may be taken as indicative of such a currency at a time when coinage of definite weight and value did not exist. A similar currency appears to have been in use among certain western communities at a much later period. A Norse law made about 1220 alludes to an established ring money, of which, however, each ring was of definite weight. It has been suggested that many ancient Celtic ornaments of gold and silver had a definite weight and value to fit them for exchange purposes; but, while it is certain that these objects served both for personal adornment and for purposes of traffic, it has not been proved that they were made to any standard of weight or value. Caesar mentions that in Gaul and Britain gold and silver rings were used as money. Among the modifications of ring money in use in different countries may be mentioned the silver fish-hook money of Ceylon, mentioned by Tavernier, of the form of a flat wire bent into a hook, and issued as late as 1659. At the present day ring money for African traders is regularly manufactured at Birmingham of copper, or an alloy of copper, and is known under the name of 'Manillas.'

Ring Ouzel (*Turdus torquatus*, or *Merula torquata*), a species of thrush, rather larger than a blackbird. It is a native chiefly of the western parts of Europe; it spends the winter in the south of Europe, Northern Africa, Syria, and Persia, and visits more northern regions in summer. It occurs frequently in many parts of the British Islands, where it breeds even in the Orkneys, but in very few districts does it remain all the year round. It is seldom seen in the more cultivated and thickly-peopled districts, preferring mountain-slopes, heaths, and their vicinity. It begins to breed in the later part of April, and makes its nest generally in heathly banks, often under a bush.

Ring Ouzel (*Turdus torquatus*).

The nest is made of coarse grass, within which is a thin shell of clay, and an inner lining of fine dry grass. The eggs are usually four in number, and are greenish blue in colour, flecked and spotted

with reddish brown; and not infrequently there is a second brood in July. The food consists of worms, slugs, insects, and moorland berries, and the bird often makes raids upon fruit-gardens in its neighbourhood; while in vine countries it feeds largely upon grapes. In some parts of Scotland it is known as the *Moor Blackbird*. It is of a dark-brown, almost black, colour; the feathers are edged with blackish gray, the wing feathers more conspicuously with gray, and there is a broad crescentic white gorget—whence the name. The legs and feet are brownish black. The female is lighter and browner, with a narrower and duller gorget. The song consists of a few loud, clear, and plaintive notes, but is somewhat monotonous. See also OUZEL, and for the Water Ouzel, DIPPER.

Ringworm (*Tinea tonsurans*) is a disease dependent on the presence of various parasitic fungi, the two chief being the small-spored *Microsporon Audouini* and the large-spored *Trichophyton nigritiosporon*. The disease is more intractable when due to the small-spored variety. The fungus consists of a mycelium, or network of thread-like filaments, with oval, transparent spores. When found on the surface of the body the fungus grows in the epidermis; but on the scalp, where it is most common, it is chiefly seated in the interior of the hair-roots. The diseased hairs lose their elasticity and break when they have risen a line or two above the scalp.

Ringworm of the Body (*Tinea circinata*; *Tinea marginata*) first appears as a rose-coloured and slightly-elevated spot about the size of a threepenny-piece, on which a bran-like desquamation of epidermis soon begins, accompanied by slight itching. This spot gradually increases in size, but retains its circular form; and as it extends, the healing process commences at the centre, so that the circular red patch is converted into a ring, enclosing a portion of healthy skin; and a ring thus formed may continue to increase till it reaches a diameter of four inches, or even more. It is apt to affect the face, the neck, the back, and the outside of the wrist. This form of ringworm frequently terminates spontaneously.

Ringworm of the Scalp (*Tinea tonsurans*) usually occurs in children, and is especially prevalent when the nutrition is defective, or the child is of weakly constitution. In infants, and after the age of puberty, it is rare, and can usually be readily cured. It appears in the form of round, scaly, irritable patches on different parts of the head; and the irritation often occasions the formation of minute vesicles. The hairs at these spots become dry and twisted, and are easily removed, but when the disease advances they break close to the scalp if an attempt is made to extract them. The stumps, and the epidermis surrounding them, become covered with a characteristic grayish-white powder, consisting of the spores of the fungus. The diseased parts are slightly elevated and puffy, and differ from the healthy scalp in colour, being bluish or slate-coloured in dark persons, and grayish red or yellow in fair patients. The inflammation will last as long as the growth of the fungi continues; and even when they die spontaneously, as sometimes occurs, the affected spots may become bald in consequence of the hair-bulbs having become atrophied. This condition, however, generally passes off in time. In some children only single hairs here and there may become or remain affected, and such cases are particularly apt to lead to the spread of the disease, because they are difficult to detect, and often escape recognition.

Ringworm is also sometimes met with in the beard, giving rise to one form of the troublesome

disease known as Sycosis. Ringworm is extremely contagious; and when a case of it occurs in a family or a school strict precautions are necessary to prevent its spreading to others. The greatest care should be taken that no brushes, sponges, towels, caps, &c., touched by the patient are used by others. When one child in a family gets ringworm, the others should have the hair cut short at once and the head washed daily with some antiseptic lotion in order to prevent infection. No child with ringworm should be allowed to go to school, unless under very special precautions, nor to the hatter or hairdresser; and intercourse with other children should be permitted as little as possible.

Treatment.—Ringworm of the body is usually not difficult to cure. The application of some parasiticide, white precipitate ointment, solution of sulphurous acid, tincture of iodine, usually kills the parasite in a week, and ends the disease. Ringworm of the scalp, on the other hand, is often an extremely intractable affection, because the parasite extends deep into the hair-follicles, and it is very difficult to bring the remedies employed satisfactorily in contact with it in this situation. An ointment containing white precipitate, sulphur, salicylic acid, oleate of mercury, or similar drugs may be rubbed well into the affected patches night and morning. Blistering is sometimes employed as a stimulant to the skin; and removal of the hair by careful exposure to the X rays is the favourite treatment at the present time. The fungus is easily killed after the hair drops out, and the hair should grow again after recovery.

Ringworm in the lower animals, as in the human subject, consists of the growth of a vegetable fungus on the surface of the skin, is common amongst young animals, is decidedly contagious, and communicable from man to the lower animals, and probably, also, from the lower animals to man. Commencing with a small itchy spot, usually about the head or neck, or root of the tail, it soon spreads, producing numbers of scurfy circular bald patches. It is unaccompanied by fever, and seldom interferes seriously with health. After washing with soap and water, run over the spots lightly every day with a pencil of nitrate of silver, or rub in a little of the red ointment of mercury, or some iodide of sulphur liniment.

Riobamba, capital of Chimborazo province, Ecuador, 102 miles S. of Quito; pop. 20,000.

Rio Bravo. See RIO GRANDE.

Rio Cuarto, the second city in the Argentine province of Córdoba, formerly called Concepción, occupies an important strategic situation on the river of the same name, 500 miles NW. of Buenos Aires, and 170 by rail S. of Córdoba. Pop. 20,000.

Rio de Janeiro, a maritime state of Brazil, lying between Espírito Santo, Minas Gerais, and São Paulo. Area, 16,000 sq. m.; population, 1,560,000. The coast is low and swampy, the interior mountainous and healthy; the chief ranges are the Serras dos Órgãos (5750 feet) and da Mantiqueira in the extreme west (8900). The principal river is the Parahyba. There are still considerable forests, though they have been greatly thinned. Coffee is the chief agricultural product, and after that sugar and cotton. The capital is Niteroy (pop. 86,000), which from 1894 to 1903 was superseded by Petropolis. The German colonies in the state have a considerable population. The city of Rio is not in the state.

Rio de Janeiro, actual capital of Brazil, on the west side of one of the most magnificent natural harbours in the world. An inlet of the Atlantic, the bay of Rio de Janeiro runs northwards for some 15 miles, varying in width from 2 miles to 7; it is girdled on all sides by picturesque

mountains, covered with tropical vegetation. The entrance, which is less than a mile wide, passes between two bold headlands, on one of which is a steep conical mass called the Sugar-loaf (1270 feet). The city and its suburbs stretch nearly 10 miles along the shore, climbing up the numerous irregular eminences and dipping into the little green valleys between them, whilst great mountain-ranges (1500 to 3000 feet) shut in the background. About 3 miles SW. of the city stands the precipitous cone of Corcovado (2336 feet), up which a cog-railway carries many thousands of visitors every year to enjoy the magnificent view. The streets are mostly narrow and often mean, and the houses and public buildings, though generally quaint and gay with colon, seldom boast of any very striking architectural features. But the building of new suburbs and of the Avenida Rio Branco with its fine buildings in 1904-6 has transformed Rio. It possesses very useful public institutions, as the vast hospital of La Misericórdia, the national library (1807), the national museum (with unique collections), the large lunatic asylum (1841) at the suburb of Botafogo, the botanical gardens with a celebrated avenue of palms (beyond Botafogo), the observatory, the Geographical and Historical Institute (1838), the former royal palace at São Christovão, the arsenal, the naval dockyards, the academy of fine arts, a cadet-school, a school of medicine, a conservatory of music, a polytechnic school, and the noble municipal theatre (1906). In spite of a good water-supply, chiefly by an aqueduct (1750) 12 miles long, and modern sewage-draining, the city remained unhealthily until yellow fever, which prevailed in the hot season, was stamped out in the first decade of the 20th century when war was waged against the mosquito *Stegomyia*. The natives are styled Cariocas. Pop. (1872) 274,972; (1920) 1,157,873, including many foreigners—Portuguese, British, French, and Germans.

Rio is also the commercial capital. The exports, of which the most important is coffee, go to the United States, Germany, Great Britain, and France. The imports, chiefly cotton, gold and silver, metals, wool, provisions, and machinery, are from Great Britain, Uruguay, the Argentine Republic, France, and Germany. The whole sea-frontage of the city is lined with quays, and in 1889, and again in 1903, extensive new works were begun, embracing a magnificent marine drive, many miles of docks and deep-water quays, with railways, &c. Further great extensions have been sanctioned since. The city possesses cotton, jute, and silk mills, tobacco and hat factories, machine-shops, tanneries, &c.

On 1st January 1531 a Portuguese captain, Alphonso de Souza, entered the bay, and thinking it was the mouth of a large river, he called it Rio de Janeiro—i.e. January River. The French established themselves on one of its islands (Villegagnon) in 1555; but they were driven away by the Portuguese in 1567. Rio was founded in the preceding year, was plundered by Duguay-Trouin in 1711, supplanted Bahia as the capital of the viceroy in 1763, and in 1822 was made the capital of the empire of Brazil. The revolution of 15th November 1889, which transformed the empire into a republic, centred in Rio; and its bay was the scene of most of the naval fighting in the revolution of 1893-94. The federal district in which the city stands (area, 450 sq. m.; pop. 1,158,000) is administered directly by the federal authorities.

Rio de Oro, since 1885 a Spanish possession on the north-west coast of Africa, between Cape Blanco and the Wadi Draa, is in soil and climate part of the Sahara. Area (including Adrar), 100,000 sq. m.

Rio Grande, also *Rio Grande del Norte* and *Rio Bravo del Norte*, a large river of North

America, rises in the San Juan Mountains in south-western Colorado, and flows generally south-eastward into the Gulf of Mexico, forming on its way the entire boundary between Texas and Mexico. Its length is about 1800 miles; it is for the most part a shallow stream, but small steam-boats can ascend for nearly 500 miles. Its chief affluent is the Rio Pecos.—See also, for other Rio Grandes, PARANÁ and SENGAMBIA.

Rio Grande do Norte, a maritime state of Brazil, occupies the north-east angle of the country, and is bounded on the N. and E. by the Atlantic. Area, 20,000 sq. m.; population, 537,000, one-half Indians. It derives its name from the river Rio Grande, which flows into the Atlantic at the capital, Rio Grande do Norte or Natal (q.v.); but the principal river is the Piranhas. The surface is flat along the shores, which are skirted by dangerous shoals and reefs, but is mountainous in the interior. The principal crops are sugar and cotton; large herds of horses and cattle are reared on the extensive pastures.

Rio Grande do Sul, the southernmost province of Brazil, is bounded on the N. and W. by the river Uruguay, on the S. by the republic of Uruguay, and on the E. by the Atlantic. Area, 110,000 sq. m.; pop. 2,183,000, including many thousands of Germans and Italians. The northern portion of the province consists of an elevated plateau, the edges of which are heavily timbered; the southern half is a rolling grassy plain, on which large numbers of cattle are kept. The climate is healthy, well suited for Europeans. All the cereals and fruits of central Europe can be grown advantageously, and the immense agricultural resources of the province are being developed. The fisheries are of some importance. Along the coast stretch the two lagoons, Dos Patos (174 miles long by 34 wide) and Mirim, connected by a navigable channel. There are productive oil-wells. Cattle-breeding is the most important industry. The principal towns are Porto Alegre (q.v.), the capital, Rio Grande, and Pelotas.—The town of Rio Grande stands on the south side of the strait leading into the southern end of the Lagoa dos Patos. Pop. 50,000. The sand-bar that obstructed the entrance has been removed. The harbour has been deepened, and Rio Grande has become a great port for southern Brazil, exporting fruit and vegetables, lard, hides, and beef. The new port (on reclaimed ground) is a mile and a half from the town and old port.

Rioja, LA, a western province of the Argentine Republic, with an area of 38,000 sq. m. and a pop. of about 90,000. Much of it is desert, but in the west there are very fertile Andes valleys, where wheat, maize, vines, cotton, and tropical fruits are grown. Copper, silver, and gold are mined.—LA RIOJA, the capital, founded in 1591, lies at the foot of the Sierra Velasco, among orange groves and vine-clad hills, 350 miles by rail NW. of Córdoba. Pop. 10,000.

Riom, a town of France (dept. Puy-de-Dôme), is picturesquely situated on a hill, 8 miles by rail N. of Clermont-Ferrand. It is built of dark lava, and is a perfect treasury of domestic architecture, especially of the Renaissance period. Pop. 10,000.

Río Muni, or BATA, the mainland portion of Spanish Guinea, on the west coast of Africa, forest-clad, with a swampy coast. Area, 10,000 sq. m.; pop. 150,000; capital, Bata (8000).

Rion. See PHASIS.

Rio Negro, (1) one of the principal affluents of the Amazon River, rises as the Guainia in south-eastern Colombia, and flows east into Venezuela, then south into Amazonas in Brazil, and again east

and south-east until it empties into the Marañon, after a course estimated at 1350 miles. Its chief tributary on the right is the Uaupes; on the left it receives the Cassiquiare (q.v.), by means of which communication is established between the Orinoco and the Amazon, and also the Cababuri, Branco, and other streams. It is over a mile broad when its clear, ink-black stream enters the yellow, muddy Amazon. A few miles from its mouth is Manáos (q.v.), on the left bank; and higher up the river opens into great lagoons, nearly choked with numerous islands. See A. R. Wallace's *Travels on the Amazon and Rio Negro*.—(2) A river of Argentina, which rises in the Andean lake of Nahuel-Huapi, flows north-east as the Cuyunilla and afterwards the Limay, and receives the name of Rio Negro at its junction with the Neuquén, after which it flows east and south-east into the Atlantic Ocean. It is over 500 miles long, and for small steamers it is navigable all the way. Near its mouth there are great saline lakes, from which immense quantities of salt are collected. It bounds on the north and gives its name to a national territory, formerly part of Patagonia, and now containing an area of 80,000 sq. m. of for the greater part level but barren soil. The chief town is Viedma (pop. 5000), 20 miles from the mouth of the Rio Negro.

Rionegro, a town in the centre of Colombia, some 15 miles SE. of Medellín. It was founded in 1545, and the National Convention met here in 1863. Pop. 9000.

Rionero, a town of Southern Italy, 12 miles N. of Potenza; it suffered greatly from earthquake in 1851. Pop. 11,000.

Riot consists in the joint unlawful action, by breach of the peace or by causing terror to the public, of three or more persons assembled together whether they originally assembled for these purposes or no. When a riot becomes formidable any justice of the peace may command the persons assembled, if not less than twelve in number, to disperse peaceably by a form of words called reading the Riot Act (1 Geo. I. chap. 5), thus: 'Our Sovereign Lord the King (or Lady the Queen) chargeeth and commandeth all persons being assembled immediately to disperse themselves, and peaceably to depart to their habitations, or to their lawful business, upon the pains contained in an Act of King George for preventing tumults and riotous assemblies. God save the King (or Queen).' (The omission of these last four words makes the reading nugatory.) To justify the use of military force in the prevention of serious outrages and damage to persons and property, it is not necessary to wait for the proclamation being read, still less to wait for an hour after it has been read. Though death or wounds result to those composing the mob, such hurt is not a criminal offence. The rioters are guilty of felony, and are liable to penal servitude for life. Prosecutions under the Riot Act must be commenced within twelve months of the time of committing the alleged offence. Sometimes the Riot Act is read more than once during the disturbance, in which case the second or third reading does not supersede the first. The Riot Damages Act, 1886, provides compensation from the rates to those whose property is damaged during a riot. Less serious than riot are *unlawful assembly*, a meeting of three or more for an unlawful object, but where no part of the object is actually carried out; and *raout*, where the assembly proceeds to execute the act, but does not actually accomplish it; and *affray*, that is, a fight between two or more in some public place (e.g. a prize-fight), but it must not be premeditated. In private the disturbance would be an *assault*.

Río Tinto, a river in southern Spain, in the province of Huelva, near whose sources are rich copper-mines; copper and sulphur minerals are exported from the port of Huelva (q.v.), 45 miles distant by rail, near the mouth of the river. These mines were worked by the Romans—their *Tharsis*. During the years of Moorish supremacy they were unused, but they have been worked again since the middle of the 16th century.

Riparian Rights. See RIVER.

Ripley, (1) a town of Derbyshire, 10 miles NNE. of Derby, with silk-lace, candle-wick, and horsehair-cloth manufactures and large neighbouring collieries and ironworks. Pop. (1851) 3071; (1891) 6815; (1921) 13,560.—(2) A village in the West Riding of Yorkshire, on the Nidd, 3½ miles NNW. of Harrogate. Rebuilt in 1829–30, it has an hôtel-de-ville (1854), an interesting church, and Ripley Castle (1555), where Cromwell is said to have slept the night before Marston Moor.

Ripley, GEORGE, was born at Greenfield, Massachusetts, 3d October 1802, graduated at Harvard in 1823, afterwards studied theology there for three years, and was ordained to a pastorate in Boston. This he held till 1841. In the meantime he had joined actively in the Transcendental movement—the first meeting of the club was at his house in 1836; and on leaving the pulpit he at once started the Brook Farm (q.v.) experiment. This came to an end in 1847, and Ripley removed to New York, when he afterwards engaged in literary and journalistic work. He was joint-editor with Charles A. Dana of Appleton's *New American Cyclopædia*. He died 4th July 1880. See Life by O. B. Frothingham in the 'American Men of Letters' series (1882).

Ripon, a city in the West Riding of Yorkshire, on the Ure, 23 miles NW. of York, 28 N. of Leeds, and 11 N. of Harrogate. A monastery, founded here in 660 by St. Cuthbert and other monks of Melrose, was granted about 664 to St. Wilfrid, who rebuilt the church with stone, and dedicated it to St. Peter. Willibrod, the apostle of the Frisians, was trained in this monastery, which in 678 was made the seat of a short-lived bishopric, re-created in 1836 after a lapse of more than eleven centuries. The beautiful minster, which from the Conquest to the Dissolution was the church of Augustinian canons, was built between 1154 and 1520, so exhibits every variety of style from Transition-Norman to Perpendicular. A cruciform pile, 266 feet long, with three towers 120 feet high, which lost their spires in 1660, and with a Saxon crypt, where a hole called 'St. Wilfrid's Needle' was anciently used as an ordeal of chastity, it suffered much through the Scots (1319), decay, and vandalism, and in 1861–76 was restored by Sir G. G. Scott. An obelisk, 90 feet high, in the market-place was erected in 1781 by W. Aislabie, for sixty years one of the two members for Ripon, whose representation was reduced to one in 1867, and merged in the county in 1885. A free grammar-school was founded in 1546. Studley Royal is 2 miles south-west; and near it is Fountains Abbey (q.v.). Ripon spurs, once famous, belong to the past, but saddle-trees are still manufactured, besides varnish, machinery, &c. The municipal borough was chartered by James I. Ripon is a spa. Pop. 8400.

Ripon, FRIDERICK JOHN ROBINSON, EARL OF, was born 1st November 1782, the second son of the second Lord Grantham. After graduating at Cambridge he entered parliament in 1806 as a moderate Tory, and had successively been Under-secretary for the Colonies, Vice-president of the Board of Trade, and Chancellor of the Exchequer, when, having that same year been created Viscount

Goderich, in August 1827 he became head of a seven months' administration. He held office afterwards as Secretary for the Colonies, Lord Privy Seal, and President of the Board of Trade; in 1833 was created Earl of Ripon; and died 28th January 1859.

GEORGE FREDERICK SAMUEL ROBINSON, MARQUIS OF RIPON, was born in London 24th October 1827, and succeeded his father as Earl of Ripon and Viscount Goderich, his uncle as Earl de Grey, Baron Grantham, and a baronet. Since 1852 he had sat in parliament as a Liberal for Hull, Huddersfield, and the West Riding, and he became successively Under-secretary for War (1859), Under-secretary for India (1861), Secretary for War (1863), Secretary of State for India (1866), Lord President of the Council (1868), Marquis of Ripon (1871), Viceroy of India (1880-84, where he was popular with the natives, unpopular with Anglo-Indians), First Lord of the Admiralty in 1886, Colonial Secretary in 1892 and 1894, and Lord Privy Seal in 1906. From 1874 a Roman Catholic, he died 9th July 1909.

Ripon Falls. See NILE.

Rip Van Winkle, the hero of Washington Irving's delightful sketch (1820), a scapgrace who seeks refuge from a scolding wife in the forests of the Catskill Mountains. There he falls in with Hendrick Hudson and his crew of the *Half Moon* who are playing at ninnies in a secluded hollow. The balls as they roll echoing along the mountain like rumbling peals of thunder. Rip is directed to wait on them, and while doing so tastes and returns to the liquor he hands, till his senses for sake him. He awakens on a bright summer morning, his dog gone, a rusty firelock by his side, his beard a foot long, and in the village he finds new buildings, new names over the doors, new faces at the windows. His sleep has lasted twenty years, and meantime the American Revolution has passed and left all things changed. Rip, however, is recognised by some of his old cronies, and finds a home at his daughter's house. The story has been often dramatised in America, but no version has held the stage except Bonicault's (1865), with which the name of Joseph Jefferson is identified. The opera by Planquette (1882) also deserves mention, as keeping pretty closely to the story.

Rishanger, WILLIAM, a monk of St Albans, who styles himself 'Chronigraphus' in an extant memorandum written by himself in 1312. He tells us, moreover, that he had been forty-one years a monk, and was then sixty-two years old, so that he must have been born in the year 1250. It has been usual to consider his *Chronica*, which covers the period from 1259 to 1307, as a continuation of Matthew Paris, and it has been to a large extent borrowed from the *Annales* of the Dominican friar, Nicholas Trivet. As a chronicler Rishanger is full and truthful, but his work is fragmentary towards the close, and besides some confusion has crept into the order of the narrative. The story is told with considerable spirit, and reveals high admiration for Simon de Montfort. The *Willelmi Rishanger Chronica et Annales*, forming vol. iii. of the *Chronica Monasterii S. Albani*, was edited for the Rolls Series by H. T. Riley (1865).

Rishl is the title given to the inspired poets of the Vedic hymns. See VEDAS.

Ristori, ADELAIDE, a great actress, born 26th January 1821, at Cividale in Friuli, died 8th October 1906. Her parents were strolling players, and she almost began life in the theatre. At the age of fourteen she played in *Francesca da Rimini*, and in a few years became the leading Italian actress. In 1847 her marriage with the Marquis Del Grillo (died 1861) temporarily interrupted her dramatic

career; but she soon returned to the stage. After having acted in Italy for some years with immense applause, she presented herself before a French audience in 1855, when Rachel was at the height of her fame. But Ristori won a complete triumph; and thereafter gained fresh laurels in nearly every country of Europe, in the United States (in 1866, 1875, and 1884-85), and in South America, where her magnificent tragic acting roused the greatest enthusiasm. The rôles in which she especially shone were Mary Stuart (Schiller's), Elizabeth (Giacometti's), Medea and Marie Antoinette (Legouvé's), Lady Macbeth, and Adrienne Lecouvreur (Scribe's). See her *Studies and Memories* (Eng. trans. from French, 1888).

Ritchie, LADY RICHMOND. See THACKERAY.

Ritornello, in Music, in its original sense, a short repetition, like that of an echo, or a repetition of the closing part of a song by one or more instruments. The same term has, by later stages, been applied to all symphonies played before the voices begin which prelude or introduce a song, as well as the symphonies between the members or periods of a song. The name is also given to the oldest form of the Italian popular poetry, and consists typically of a strophe of three iambic lines, the first and third rhyming.

Ritschl, ALBRECHT, Protestant theologian, was born 25th March 1822, at Berlin, where his father was a clergyman. His university studies were carried on at Bonn, Halle, Heidelberg, and Tübingen. In 1846 he 'habilitated' at Bonn, the subject of his thesis (in the treatment of which he substantially reflected the views of his Tübingen master, Baur) being the relation between the gospel of Marcion and the canonical gospel of Luke. His next published work, on the origin of the early Catholic Church, was of similar tendency, though seeking to modify the conclusions of his contemporary Schweigger as to the influence and extension of Ebionitism in the apostolic and post-apostolic age; but in the second and completely rewritten edition of the same work he took up towards the fundamental positions of the Tübingen school an attitude of antagonism, which he ever afterwards maintained. He now denied the alleged Ebionitism of primitive Christianity altogether, and, accepting as genuine the epistles of James and Peter as well as the Apocalypse and Acts, maintained that none of the apostles had regarded the law as religiously binding, and that they only continued its observance as a national custom among Jews, leaving Gentile converts free. Ritschl, who had become professor extra-ordinarius of Theology at Bonn in 1853, was promoted to an ordinary professorship in 1860, and in 1864 was transferred to Göttingen, where the rest of his life was spent. His lectures, especially those on Christian ethics, soon became famous for their originality and vigour. While in Bonn he had also published a tract on the relation between the church and its confession (1854), and a Latin dissertation on the wrath of God (1859). The list of his Göttingen publications includes, besides his principal work, a treatise on Christian perfection (1874), a tract on conscience (1876), a history of Pietism (1880-86; 3 vols.), a tract on theology and metaphysics (2d ed. 1887), and a volume containing three academical discourses (1887). He died at Göttingen, 20th March 1889.

His principal work, on the Christian doctrine of justification and reconciliation, was published in three volumes (1870-74; 3d ed., with noteworthy alterations, 1888), the first of which traces the history of the doctrine, the second discusses its biblical premises, and the third its theological meaning. There is an English translation of this great treatise

(vol. i. 1871; 2d edition, 1900). The work as a whole expounds with much force and effectiveness a theological system marked by great dialectic acuteness and subtlety, ingenious and searching exegesis, and bold disregard of ecclesiastical tradition. The distinguishing feature of the Ritschlian theology is perhaps the prominence it gives to the practical, ethical, social side of Christianity. As a reasoned system it starts from a definite theory of cognition, eclectically derived from Kant through Lotze, which has sometimes been called a subjective idealism, and criticised as denying all objective reality to the objects of theology. But hardly with justice. For, though doubting the possibility of demonstrating God to the merely speculative intellect, Ritschl holds that God is really, effectively, practically revealed to man on his religious side; in other words, becomes known to those who have found their need of Him. God is to be thought of as love; there is no other conception of equal value. In particular the conception of His holiness is an obscure one, and His righteousness is in fact identical with His grace. All metaphysical statements as to His absoluteness or existence through, or in, or for Himself are of no religious value. In connection with his doctrine of God, Ritschl attaches high importance to the conception of the church as being the community within which alone men can have reconciliation with God and freedom from the sense of guilt, and so be able to act from motives of love, and realise that human and divine fellowship of perfect love which is the kingdom of God. In this Ritschl expressly differs from Schleiermacher (in many other respects a master whom he follows closely); but, while rejecting the Protestant formula of the latter, (that the relation of the individual to the church depends on his relation to Christ, he is very far removed from the position of Roman Catholicism. His doctrine of Christ attaches no value to the hypostatical distinction of persons in the God-head or to the ecclesiastical doctrine of the two natures or the three offices, but states the divinity of Christ in terms of His peculiar and unique relation to the church, which He founded by His life and work on earth. This work was atoning work; but the reconciliation with God and immunity from the sense of guilt which He secured for the church were obtained not by vicarious endurance of the punishment due to sinful men, but by His perfect fulfilment, in loving deed and word, of the work of His calling, and by His perseverance in it in spite of all opposition, and by His patient endurance of all suffering even unto death. The justification possessed by the Christian as a member of Christ's community is practically shown in his freedom or dominion over the world. This dominion is exercised, in trust in God's providence, by patience, by humility amid all the vicissitudes of life, by faithfulness of the individual to his calling as being his contribution to the kingdom of God, and by Christian prayer, which is chiefly thanksgiving or humble recognition of the divine rule. Ritschl is usually classified as an 'eclectic mediating theologian'; perhaps 'intermediate' would be a better word, for his theology is uncompromisingly opposed alike by the 'rationalist' and 'orthodox' parties. The Ritschlians became a large and important school in Germany, the most prominent among them being Kaftan, Herrmann, and Harnack.

See the Life by his son Otto (2 vols. 1892-96); Stahlin, *Kant, Lotze, and Ritschl* (trans. 1889); works on Ritschlianism by Pfleiderer (1891), Micke (1891), Plönnigsdorf (1896), Orr (1898, 1903), Garvie (1899), and Edgill (1910).

Ritschl, Friedrich Wilhelm, classical scholar, was born at Grossvargula, near Erfurt, 6th April 1806. He studied at Leipzig and at Halle, held chairs of Philology at Breslau (from 1834),

Bonn (from 1839), and Leipzig (from 1865), and died at Leipzig on 9th November 1876. As a teacher he exercised great influence over his pupils, amongst whom were Curtius, Ilne, Bruggmann, &c. His greatest work is an edition of Plautus (3 vols. Bonn, 1848-54; new ed. 1881-87), provided with the richest critical apparatus. This standard work was preceded by *Peregrina Plautina et Terentiana* (Leip. 1845). He achieved a second triumph in the department of Latin inscriptions, his collection, *Præcæ Latinitatis Monumenta Epigraphica* (Berlin, 1864), being the forerunner of the great *Corpus Inscriptionum Latinarum*. Ritschl's numerous critical papers and dissertations are collected in *Opuscula Philologica* (5 vols. Leip. 1867-79). Ribbeck's Life of him is the best (2 vols. 1879-81); see also another by L. Müller (1878).

Ritson, Joseph, a learned and honest, but pedantic, acrid, and ill-mannered antiquary, was born of Westmorland yeoman family at Stockton-on-Tees, in 1752. He was bred to the law and practised as a conveyancer in London, but was enabled by the profits of the office of Deputy High-bailiff of the Duchy of Lancaster to give most of his time to antiquarian studies. He made himself as notorious by his crazy vegetarianism, his whimsical spelling, and irreverence, as by the acerbity of his attacks on much bigger men than himself. Scott alone of his contemporaries kept good terms with him, but then none other had his large heart and genial humour. Undoubtedly Ritson's mind was deranged, and he died in a fit of gloom, 3d September 1803. Ritson's industry was remarkable, and all his forty books are valuable despite the blemishes in which they abound. His first important work was an abusive but well-grounded attack on Warton's *History of English Poetry* (1782). Next year he assailed Johnson and Steevens for their text of Shakespeare; in 1790 he attacked Bishop Percy with absurd tenacity in the preface to a collection of *Ancient Songs*; in 1792 appeared his characteristic *Cursory Criticisms on Malone's Shakespeare*.

Other works were *A Select Collection of English Songs* (3 vols. 1783); *Pieces of Ancient Popular Poetry* (1791); *The English Anthology* (3 vols. 1793-94); *A Collection of Scottish Songs* (2 vols. 1791); *Poems*, by Laurence Muret (1795); *Robin Hood: a Collection of all the Ancient Poems, Songs, and Ballads* (2 vols. 1795); *Bibliographica Patena: a Catalogue of English Poets of the XII. - XVI. Centuries* (1802); and *Ancient English Metrical Romances* (3 vols. 1802). His various North Country *Garlands* and his *Essay on Abstinence from Animal Food as a Moral Duty* (1802) were less important. There are Lives by Joseph Haslewood (1824) and A. Burd (Illinois, 1917); his Letters were edited, with a Life, by Sir N. Harris Nicolas (2 vols. 1833).

Ritter, Heinrich, German philosopher, was born at Zerbst in Anhalt on 21st November 1791, studied theology and philosophy at Halle, Göttingen, and Berlin; was professor of Philosophy successively at Berlin (1824-33), Kiel, and Göttingen (1837-69); and died in Göttingen on 3d February 1869. His fame rests upon an extremely careful and impartial *Allgemeine Geschichte der Philosophie* (12 vols. 1829-51), with a continuation carrying on the work from Kant (1853); and upon *Die christliche Philosophie* (2 vols. 1858-59).

Ritter, Karl, geographer, was born 7th August 1779 at Quedlinburg in Prussia, was educated at Schnepfenthal under Guis Muths, studied in Halle, was in 1820 nominated professor of Geography at Berlin, became subsequently member of the Academy and Director of Studies of the Military School, and died 28th September 1859. With Ritter as the founder of general comparative geography begins a new epoch in the history of the science. His chief work (uncompleted)

was *Die Erdkunde im Verhältnis zur Natur und zur Geschichte des Menschen*. Besides this he wrote an *Introduction to General Comparative Geography* (1852); *Europe* (2 vols. 1807); and *The Stupas, or the Architectural Monuments on the Indo-Bactrian Royal Road, and the Colossus of Bamian* (1838). His lectures were published in three volumes (1851-63) by Daniel. See *Life by Gage* (Edin. 1867), and *Kramer, Carl Ritter, ein Lebensbild* (2d ed. Halle, 1875).

Ritual (Lat. *rituale*, 'book of rites'), one of the service-books of the Roman Catholic Church, in which are contained the prayers and order of ceremonial employed in the administration of certain of the sacraments (communion out of Mass, baptism, penance, marriage, extreme unction) and other priestly offices of the church, forms for churchings, burials, and blessing. In its present form it dates from the Council of Trent, which directed a revision of all the different rituals then in existence (also known as *manuale*, *sacerdotale*, &c.), which were numerous, and exhibited considerable variety of detail. Paul V., in 1614, published an authoritative edition, which has frequently been reprinted, and of which a further revision was issued by Benedict XIV. Besides the Roman Ritual there are many diocesan rituals, some of which are of much historical interest. In the Greek Church, as in the other eastern communions, the Ritual forms part of the general collection (which contains also the Eucharistic service) entitled *Euchologion*. In the Anglican Church the *Book of Common Prayer* may be said to contain the Ritual. The most approved commentary on the Roman Ritual is that of Barrufaldo (3d ed. 1763).

Ritualism, the name popularly but inaccurately given to the remarkable increase of ceremonial in the Church of England since about 1860-65. It may be considered as a development of Tractarianism, though it is one not contemplated by the authors of that movement, whose aim was rather to disseminate doctrines than to introduce ritual changes. Dr Pusey and his associates deprecated any innovations in the way of conducting the services, anything of ritualism, or especially any revival of disused vestments. Collateral causes of the movement may be said to be the great advance of æsthetic taste, and the increased cultivation of the fine arts in the service of religion; as also the extended study by the clergy of ancient liturgies, and the connection discovered to exist between them and the offices of the English Church. With the spread of High Church principles certain changes in the mode of conducting divine service had been introduced by the clergy, which, though unpopular at first, were widely adopted, and up to a certain point had received the sanction of the law. But the restored church with low and open benches; the separated chancel; the altar-table with coverings of different colour according to the ecclesiastical seasons, and candlesticks and a cross upon or over it; choral services, and weekly celebration of the communion, were all that had hitherto been attempted. To these comparatively small alterations important additions were subsequently made, bringing the usages of the Church of England nearer those of the Roman communion, such as special vestments at the celebration of the holy communion, and at certain other times—for the celebrant an alb, stoles of different colour, according to the seasons, and chasuble, and for the assisting ministers albs with tunics; lighted candles on the altar at holy communion; incense burned either in a 'thurible' or in a standing vessel; the mixing of water with wine for the communion; the use of wafer-bread;

elevation of the elements either during or after consecration; and processions with crosses, banners, and vested attendants.

The Public Worship Regulation Act (1874), passed after fierce discussion in both Houses of Parliament, was expressly designed, as Disraeli admitted, for the repression of ritualistic practices, and constituting a new judgship for offences against the rubrics (see ECCLESIASTICAL COURTS). Numerous trials (see ENGLAND, CHURCH OF) took place, and several clergymen charged with ritualistic practices were imprisoned (as A. Tooth, 1877; Pelham Dale and Emright, 1880; S. F. Green, 1882; J. C. Cox, 1887; see also MACKONACHIE). In 1889-90 proceedings were taken in the Archbishop of Canterbury's court against the Bishop of Lincoln. The decision was given in November 1890, and related to nine heads: (1) The mixing of the cup during the service is to be discontinued; (2) but the use of a cup already mixed is not an ecclesiastical offence; (3) the court dismissed the charge as to ablation after service, holding that all the bishop had done was the reverent consumption of what remain of the consecrated elements; (4) as to the eastward position, the court decided that there is liberty as to using the north end of the altar or the north end of the west side; (5) the breaking of the bread must be performed so as to be visible to the people; (6) the singing of the anthem 'O Lamb of God' is not prohibited; (7) candles which are kept lighted throughout the service are not an offence; (8, 9) the sign of the cross must be discontinued both in absolution and in benediction. In 1899 the two archbishops pronounced against the use of incense and processional lights, and in 1900 against reservation of the consecrated elements. A royal commission was appointed in 1904 and reported in 1906, singling out certain practices as grave enough to call for immediate suppression. The movement meanwhile went on; decisions were given from time to time against ritualists; and the thoughts of many on both sides were turned to Prayer-book revision. See the articles ALTAR, CHASUBLE, LIGHTS, VESTMENTS, &c.; ENGLAND (CHURCH OF), and PRAYER (BOOK OF COMMON).

Riukyu. See RYÜKYÜ.

Rivarol, ANTOINE, French writer, was born at Bagnols in Languedoc, 26th June 1753. Though but the son of an innkeeper, when he appeared in Paris in 1780 he laid dubious claim to rank, and soon worked his way by his wit into the best society of the time. Already he had written his treatise, *Sur l'Université de la Langue Française* (1784), and paraphrased rather than translated the *Inferno*, when in 1788 he set all Paris laughing at the sarcasms in his *Petit Almanach de nos grands Hommes pour 1788*. At the Revolution he took his place in the royalist ranks, and saved his head by emigrating in June 1792. Supported by royalist pensions, the 'Tacitus of the Revolution,' as Burke styled him in one of the least happy of hyperboles, employed himself fitfully in writing pamphlets and weaving dreams of books to be written, in Brussels, London, Hamburg, and Berlin. He had married an English wife, but she quarrelled with him, and not without reason. Rivarol died at Berlin, 13th April 1801.

His works were collected by Chénedollé and Fayolle (5 vols. 1805), but their terse epigrammatic quality shows better by compression in the *Esprit de Rivarol* (2 vols. 1808) and the *Œuvres Choies*, edited by Lescuré (1862; new ed. 1880). See books by Lescuré (1883) and Le Breton (1895), and Remy de Gourmont's *Promenades Littéraires* (iii. 1909).

Rivas, a decayed town of Nicaragua (q.v.), 6 miles from Lake Nicaragua, capital of the fertile

department of Rivas, between the lake and the Pacific Ocean; pop. 16,000.

Rivaux Abbey. See RIEVAULX.

Rive-de-Gier, a town of France (dept. Loire), stands on the Gier, in the middle of the best coal-field in France, 13 miles N.E. of St Etienne by rail. It was formerly a stronghold, surrounded by high walls, and defended by a castle. In 1815 it had less than 4000 inhabitants; now about 16,000. Around the town are coal-mines, and in it are glass-works, works for railway material, and iron and steel factories.

River. Water falling on the land in the form of rain, or resulting from melting snow, or rising to the surface in springs, flows over the surface to a lower level. Where two slopes of land dip together the surface drainage collects to form a stream, and when evaporation is not very rapid several such streams ultimately unite and the volume of water they carry flows to the sea or to a salt lake. Small streams are termed runnels, rivulets, rills, brooks, becks, or burns; large streams are termed rivers, but the word has no precise reference to the magnitude of the stream to which it is applied. Dr Johnson gives as definitions: 'Brook, a running water less than a river;' and 'River, a kind current of water bigger than a brook,' and this fairly illustrates the use of the words as popularly applied.

The beginning of a stream—whether brook or river—is called its source, and may be a spring issuing from underground, a lake or marsh in which rainfall accumulates, melting snow, or simply the gathering tricklings from falling rain. The path of a stream is its course, and is the line of lowest level from the source to the end, which if occurring in a lake or the sea is termed its mouth. The connected streams which unite in one river form a river-system. The series of convergent slopes down which a river-system flows—the land which it drains—forms its basin or catchment area, and the name watershed is also sometimes erroneously applied to it. The names watershed, water-parting, and divide are used to designate the boundary line separating adjacent basins. A watershed is always the meeting-place of the highest part of divergent slopes, and from the characteristic form of continents the main watershed of a continent is almost always the crest of a range of mountains. In many cases, however, the diverging slopes meet in a low plain the summit of which may be occupied by a great marsh whence rivers creep away in opposite directions. The basins of all the rivers draining into the same ocean are called collectively the drainage area of that ocean. The main river to which the others are said to be tributary gives its name to the whole river-system. It is often difficult to decide which of several converging streams is entitled to carry the name of the main river to its source. Some geographers give this distinction to the longest, others to that with the highest source, and others to that with the most direct course. This diversity of opinion is increased when the name of a river leaving a large lake is given to one of several nearly equal streams which enter it. Hence it is that different computers disagree as to the length of rivers. The course of a typical river has been divided into three parts, although these are not represented in all cases. The *torrential* or mountain track is the steepest, its gradient usually exceeding 50 feet in a mile, and the velocity of its current being very great. The *valley* or middle track has a gradient which is rarely greater than 10 feet and often less than 2 feet in a mile. The *plain* track nearest the mouth of a river has a gradient of only a few inches in a mile. Rivers such as the Amazon, Mississippi, Ganges, Volga, and the long rivers of

Siberia, in which the plain track is of very great length, are the most valuable for navigation, the limit of easy navigability being a gradient of about 1 foot in a mile.

The velocity of a river is proportional to the slope of the bed, but it also bears a relation to the depth of the channel and the volume of water flowing in it. On account of friction on the bottom and sides of the channel retarding the stream, the water flows fastest on the surface and in the middle. The carrying power of a river for suspended solid particles and for stones and gravel pushed along the bed depends on the velocity alone. The following table shows how rapidly the carrying power falls off as the velocity diminishes.

0 170 mile per hour	will just begin to work on fine clay.
0 340 " " "	" lift fine sand.
0 154 " " "	" lift sand as coarse as loess.
0 682 " " "	" sweep along fine gravel.
	" " " sweep along rounded pebbles 1 inch in dia
2 045 " " "	" sweep along slippery angular stones as large as an egg

Rivers in flood, even in the plain track, sometimes attain a velocity of over 5 miles an hour, and torrents may even flow as fast as 20 miles an hour. The course of a river is gradually curved out and shaped by the flow of the water. The sediment and stones carried along are powerful erosive agents in the torrential and valley tracts, and the character of the valleys or gorges produced depends largely on the geological structure of the region. The course of a river is frequently determined by lines of faults, but perhaps more often it appears to be independent of the nature of the strata. Some great rivers, notably the Volga, press against the right bank, cutting it into a steep cliff, while the left bank is left as a very gentle slope. This is explained by the directive influence of the earth's rotation (see EARTH).

Rivers are of very great importance as agents of change in dynamic geology, the form of valley they excavate being determined partly by the nature of the rocks, partly by the climate. In rainless or arid regions steep-walled Canyons (q.v.) are cut to a great depth across high plateaus; in rainy regions subaerial denudation leads to the formation of wide valleys of much gentler slopes. Bars of more durable rock crossing the course of a stream lead to the formation of Waterfalls (q.v.) or rapids from the rapid erosion of the softer strata below. The river above the obstruction is reduced to what is termed the base-level of erosion; the velocity of the current is checked, and wide alluvial deposits are laid down on either side. In course of time the bar of hard rock is completely cut through by a gorge, and the gradient of the stream is ultimately rendered uniform. In this way the common features of gorge and meadow are produced again and again along the course of a stream. The deposits of alluvium form terraces along the valley track of a river, and as the stream cuts its channel deeper they are left at various heights as monuments of its erosive power. When a river is fairly established in its valley it is, geologically speaking, a more permanent feature than lakes or mountains. Upheaval, which acts very slowly, may even elevate a range of mountains across its course, yet all the while the river, cutting its way downward, remains at the same absolute level. The Uintah Mountains, as they were upheaved, were divided in this way by the Green River, the chief tributary of the Colorado. In limestone regions the solvent power of river-water on carbonate of lime leads to the formation of Caves (q.v.) and underground rivers, which as a rule emerge from their subterranean channels on lower ground. Sometimes they do not reappear on land, but discharge their fresh water through openings in the

bed of the sea. Such submarine river entrances are not uncommon along the shores of the Adriatic, off the coast of Florida, and in other calcareous regions. When a river advances along a nearly level plain toward the sea its carrying power falls off; gravel, sand, and finally mud are deposited on its margin, and the stream pursues a peculiar winding course. During a flood the swift and muddy stream rises, overflows its banks, and widens out on the level land. The current is at once checked and a long bar of deposit forms along each margin. These are increased in height by each successive flood, and the river-bed being simultaneously silted up, broad muddy rivers like the Mississippi, Po, and Hoang ho come in time to flow along the top of a gently sloping natural embankment, the sides of which are termed levees in Louisiana. Professor Lapparent, taking Sir John Murray's data regarding the amount of sediment carried down by rivers, finds that they would suffice to wear the entire surface of the land down to sea-level in four million years. The entrances of rivers into lakes or the sea are usually marked by great banks of deposit (see DELTA), or by bars of gravel or sand. In some cases, however, such as the River Plate, the Thames, and Tay, the mixture of river and sea water is gradual, and the sandbanks are spread over a very large area, but not built up into a delta at any one place. Professor Osborne Reynolds has shown, by a remarkable series of experiments, that the form of the sandbanks is due to the outline of the coasts of the estuary and to the tides. In a few instances, such as the Firth, rivers enter deep arms of the sea in which neither banks nor bars are formed. The Congo sweeps directly into the ocean, throwing down great banks of deposit along the continental slope to right and left, but leaving a deep canon-like gully for the bed of the stream itself; a similar condition occurs where the Rhone enters the Lake of Geneva.

The ultimate source of all rivers is the condensation of water-vapour from the atmosphere in the form of rain, snow, and even dew. If the land were composed of impermeable rocks all the rain-water not lost by evaporation would run off directly over the surface, and rivers would only flow during and immediately after showers. A large part of the rainfall, however, soaks into the soil, which retains it as in a sponge, especially if the land be marshy, and allows it to flow off gradually as superficial springs. Some also percolates deeply into the rocks, ultimately emerging as deep seated springs at a great distance. The indirect and permanent supply of water to rivers by springs and by the outflow of lakes is independent of local rainfall at the time, and serves to maintain the volume of the river at a certain minimum during the dry seasons. When a river flows toward a region of great evaporation and small rainfall, such as exists in the interior of each of the great continents, evaporation removes more water than is supplied by the remote tributaries, and the stream may fail to fill the hollow it enters, and therefore cannot overflow into the sea. This is the case with the Oxus entering the Aral Sea, and the Volga entering the Caspian. It may be that evaporation is so far in excess of contributions from distant rainfall or snow-melting that the river dries up as it flows, and its last remnant is absorbed in the desert sand. This is the fate of the Murghab, the Heri-rud, the Zerashan, and many other rivers of central Asia.

Contrasted with these cases are those in which the periodical or occasional increments of direct inflow increase the volume so much as to cause a great rise of level or even extensive inundations. The annual inundations of the Nile are due to

the monsoon rainfall on the great mountains of Abyssinia, which increases the discharge at Assouan to fifteen times the amount of the river at its lowest. The Orinoco is another instance of seasonal rains producing tremendous inundations, over 40,000 square miles of the Llanos being said to be laid under water by the summer rains. The Amazon is an instance of a river which is always more or less in flood as the various tributaries attain their greatest height at different seasons. In June, when the highest level occurs in the main river, 20 or 30 miles of forest on each side of its banks are laid under water for hundreds of miles. The Ganges overflows its banks in summer when the monsoon rainfall is reinforced by the melting of snow on the Himalayas. Where the seasons of maximum rainfall and of snow-melting are different, as in the Mississippi, the Tigris, and Euphrates, there are two regular floods in the year.

The danger of flooded rivers arises from the suddenness with which the water rises and overflows narrow valleys or even plains. Frightful devastation follows the bursting of glacier obstruction lakes in mountain-valleys (see LAKE). The great rivers of Siberia remain frozen at their mouths long after the ice and snow have been melted in the interior, and broad strips on their margins are necessarily laid under water by the natural outflow being stopped. The most serious floods in the Danube and Theiss have resulted from the constriction of the channel at the Iron Gates, which prevents the flood water from passing away as rapidly as it comes down; the current of the Theiss is sometimes reversed for many miles. The widening of the channel has been repeatedly attempted as a remedy by increasing the outlet; and an elaborate system for regulating the river here, to be completed in 1895, was begun in 1890. In other cases, such as the tributaries of the Loire, and the southern rivers of the Argentine Republic, the melting snow swells the torrential track, and, on account of the abrupt change of level and the flatness of the plain, the lower part of the rivers cannot carry away the immense volume of water rapidly enough, and floods result. In some instances torrential rivers have been successfully diverted into lakes, which regulate their outflow, preventing either dangerously high or extremely low water. Great rivers which have embanked their course above the level of the plain are the most dangerous of all when flooded. The damage caused by the bursting of the levees on the lower Mississippi necessitates a great expenditure in strengthening the embankments, and the most disastrous inundations recorded in history have followed the bursting of the banks of the Hoang-ho (q.v.) and its consequent changes of course.

River water is spoken of as fresh, but it always contains a certain amount of solid matter in solution, varying from two grains in the gallon or less in rivers draining hard crystalline rocks to fifty grains in the gallon or more in limestone districts. The nature of the salts dissolved naturally differs according to the geological character of the country traversed, but all samples of river-water differ from sea-water in containing a much smaller proportion of chlorides, and a very much larger proportion of carbonates and of silica.

The temperature of rivers as a rule follows that of the air, but is subject to variations on account of the effect of rain. During sudden floods in summer the temperature of the water may fall many degrees in a few hours as the melted snow or hail precipitated on the lofty mountains is carried toward the sea.

The great rivers of Europe and Asia, such as the Rhine, Danube, Volga, Indus, Ganges, Brahmaputra, Yang-tse-kiang, afford access to the sea to

enormous populations. The Amazon, with its plain track extending for nearly 3000 miles, is in many ways less like a river than a fresh inland sea; but the Mississippi and St Lawrence, although less extensive, are of greater value for carrying sea traffic to inland places. In their torrential and upper valley tracks rivers are of use chiefly for transporting timber and driving machinery. It is interesting to note that in Switzerland, Norway, and Sweden, where there is no coal, there exist exceptional facilities for the use of water-power on account of numerous mountain-torrents. In hot countries rivers are of the utmost service in irrigating agricultural land; the Zerafschan and Murghab are entirely consumed in that service, and since the completion in 1890 of the barrage on the Nile no water escapes to the Mediterranean in the low Nile months except along irrigation canals.

THE LARGEST RIVER-SYSTEMS.

River.	Area of Basin, sq. m.	Length, miles	Annual Rainfall of Basin, in. miles	Mean Annual Discharge, cu. miles
Amazon.....	2,230,000	3400	2834	528.0

Murray.....	300,000	1500		

The statistics of this table, in which account is taken of rainfall and discharge, are taken from Sir John Murray's paper in *Scott. Geog. Mag.* iii. (1887) p. 65. The lengths in all cases and the areas of basins in those for which no rainfall statistics are available are according to the statistical tables in Justus Perthes' *Taschen-Atlas*.

Rivers in Law.—A tidal navigable river, that is to say, the portion of a river which is subject to the ebb and flow of the ordinary tides, and which is in fact navigable, is subject to the public right of navigation. The ownership of the foreshore and bed of a river, where the tide flows and reflows, is *prima facie* vested in the crown for behoof of the public, and cannot be used in any manner so as to derogate from or interfere with the right of navigation. The public right of navigation carries with it the rights necessarily attendant on it, such as the right of anchoring and of mooring. The right of navigation, which is a right of passage by water for boats or vessels, does not involve a right in the public to use the banks, e.g. to land themselves or their goods thereon, or to set up a towing-path. Such rights, which exist in the case of many navigable rivers, depend not on common law right but on usage or prescription. In addition to the right of navigation, the public have *prima facie* a right of fishing in the tidal waters. Prior to Magna Carta the crown had power to exclude the public from this right and to grant an exclusive right of fishing to individual subjects. But it is now settled that since Magna Carta no new exclusive fishery could be created by royal grant in tidal waters and that no public right of fishing in such waters, then existing, can be taken away otherwise than by act of parliament. The public right of fishing does not entitle the public to use the adjoining land above high water mark for the

purposes of fishery, either in the way of fixing nets by stakes, or drying nets, or drawing them ashore, or of drawing up or leaving boats for future use.

Rivers above the point to which the ebb and flow of the tide extends are *prima facie* private; but as in the case of many English rivers, a public right of navigation in the non-tidal waters has been acquired by immemorial use or by act of parliament. The public right of navigation in non-tidal waters, where such a right exists, does not carry with it the right of public fishery. The bed of non-tidal waters is presumed to belong to the owner of the land through which the river flows. If the river separates the lands of two owners, the presumption is that each of them is owner of the bed up to the middle of the stream (*ad medium filum*). Where in a river with well-defined banks an island divides a river into a main and subsidiary channel, the *medium filum* of the river is the centre line of the bed from bank to bank at the ordinary level of the water, and not the centre line of the main channel. Each owner of land abutting on a non-tidal river is presumed to have the right of fishing in front of his land *ad medium filum*; and where a man possesses the land on both sides of the water the presumption is that he has the sole right of fishing. The flowing water of a river is public and common in the sense that all may reasonably use it who have a right of access to it, and that none can have any property in the water itself, except in the particular portion which he may abstract from the stream and take into his possession. Riparian proprietors, i.e. the proprietors of land on the banks of a stream, have certain natural rights and duties in respect of the water of the stream. Thus every riparian proprietor has a right to use the water for its ordinary domestic purposes and for his cattle. Further, he has a right, under certain circumstances, to the reasonable use of the water for other purposes, e.g. irrigation or manufacturing purposes, provided he does not interfere thereby with the rights of other proprietors, either above or below. Subject to the ordinary use of the flowing water by upper proprietors and to such further use, if any, on their part, in connection with their property as may be reasonable in the circumstances, every riparian proprietor is entitled to have the water of the stream flow down as it has been accustomed to flow down to his property, in its natural flow, without sensible diminution or increase, and without sensible alteration in its character or quality. Accordingly, while a riparian owner may divert the water of a river for a reasonable purpose in connection with his land, e.g. erect a mill-dam across the stream within his own property and divert the water into a mill-lade, he, unless he has acquired a prescriptive right so to do, is not entitled to obstruct the water from flowing as freely as it was wont from the land of the proprietors above him, and must take care to restore the water into the stream before it leaves his land, so that the stream shall pass onwards to the land of the proprietors below him in its original channel and at its natural level. So, while a riparian owner is entitled to protect his property from the invasion of the water by erecting a bulwark, he is not at liberty to conduct his operations so as to throw the force of the current upon, or do any actual injury to, the property on the other side of the river. The right to the flow of running water, without deviation or alteration, being common to all those through whose land it flows, each of them is entitled to prevent any unauthorised interference with or use of the water inconsistent with their common rights in it, or to bring an action for loss sustained by such unauthorised interference or use.

There is no distinction between the law of England and the law of Scotland as regards questions relating to the common interests and rights of upper and lower proprietors on the banks of a river. In addition to these natural rights there may exist in relation to a river certain acquired rights. Thus rights may be acquired to interfere with a river, e.g. by diverting or obstructing or diminishing its flow, or by polluting the water, in a manner, or to an extent, not justified by natural right. Such acquired rights may be founded on grant, prescription, or act of parliament. (See EASEMENT, SERVITUDE.)

The pollution of rivers is a matter of concern not only to riparian proprietors but also to the public. If the water be polluted, a riparian proprietor, having a right to the flow of the stream in its natural state through or by his land, has, without proof of actual injury, a right to restrain the fouling of the water, unless a right to pollute the stream has been acquired by the person causing the pollution. In England the pollution of a stream may amount to a public nuisance, if it affects the health, comfort, or convenience of the public or of persons generally who come within its operation, and in that case the party causing the pollution may be prosecuted by indictment or proceeded against by information at the suit of the Attorney-general. The Public Health Acts contain provisions designed to prevent the fouling of streams. The most important statutes, however, relating to the pollution of rivers are the River Pollution Prevention Acts, 1876 and 1893, applicable both to England and to Scotland, which make special provision, regulative and administrative, for the prevention of the pollution of rivers by solid matters, by sewage, and by noxious liquids from mines and manufacturing processes, and also for the prevention of new sources of pollution. For English Law see Conlson and Forbes, *Law Relating to Water* (4th ed. 1924, by Moore); for Scots Law: Ferguson, *Law of Water and Water Rights*.

Engineering works on rivers are designed for various purposes, such as navigation, drainage and flood protection, irrigation, and water power and supply. Many British rivers have been deepened in the interests of navigation, of which the most successful instance is perhaps the river Clyde, which before 1760 was an insignificant tidal stream so encumbered by shoals that barges drawing 4 feet could reach Glasgow only on a high spring-tide. That river has been deepened to give about 38 feet depth of water at high water springs—the deepening having been carried out by training-walls in the upper reaches and by dredging the river-bed throughout its whole course of 20 miles from Glasgow to Greenock. The Grand Sluice built across the river Witham at Boston excludes the tides, thus assisting in draining the fen-lands and preventing flooding, and in the interests of navigation the sluice also holds up the water-level inside. The existence of the English fens is dependent on such sluices placed across the draining-channels to avoid the flooding resulting from high tides. The river Witham has had its lower course through sand-banks fixed by training-walls, so that its navigable depth is maintained by tidal scour. The rivers Lune and Cheshire Dee are also instances of the beneficial effect of training-walls for navigation of rivers. Large sums are spent annually in dredging the bar at the mouth of the Mersey to maintain the navigable depth. The flood waters of the Nile are impounded for the benefit of irrigation. Large reservoirs have been formed by building dams across many American, Australian, and South African rivers for the purposes of water power and supply or in order to impound flood waters, and thus reduce the height of floods in the lower reaches.

Riverina, originally the pastoral area between the Murray and the Darling, but now usually restricted to the lands between the Lachlan and the Murray. The Riverina division of New South Wales lies between these rivers to the west of a line roughly drawn from Condobolin to Albury. Erection into a state has been proposed.

Rivers, RICHARD WOODVILLE, or WIDVILE, EARL, was esquire to Henry V., and during his son's reign was made Governor of the Tower (1424) and knighted (1425). He fought in France and in England, in the Wars of the Roses for the Lancastrians. He took to wife Jaquetta of Luxemburg, widow of the Duke of Bedford, and it was their daughter Elizabeth whom Edward IV. married. This led Sir Richard Woodville to change over to the Yorkish side, and his royal father-in-law made him successively Constable of England, Baron Rivers (1448), and Earl Rivers (1466). But the favours shown to the Rivers family offended the old nobility, and their avarice aroused the enmity of the people. In 1469 Earl Rivers was seized and beheaded at Northampton, but accounts differ as to who were his executioners—whether Robin of Redesdale or the officers of the Duke of Clarence and the Earl of Warwick.—His son ANTHONY, previously known as Lord Scales, succeeded him. He stuck closely to his royal brother-in-law, who made him captain-general of the forces. After Edward's death he acted on the council of regency for his infant son, but was seized by order of Richard, Duke of Gloucester, and put to death at Pontefract in 1483.

Rivers, WILLIAM HALSE RIVERS, psychologist and anthropologist, was born in 1864, and educated at Tonbridge and Bartholomew's. From 1893 he was lecturer at Cambridge on psychology of the senses, physiological and experimental psychology (1897), and physiology of the senses (1907). He went to Torres Straits in 1898 as psychologist of the Cambridge expedition, and there discovered the great value of the genealogical method, which in 1902 he employed among the Todas. His important book on that people appeared in 1906, and in 1914 his *Kinship and Social Organisation*. Since 1908 he had been studying the Melanesians, and in 1915 his great work *The History of Melanesian Society* showed how the way in which the elements in a culture are linked together can be made to yield up the story of long past migration. This book had a very important part in persuading anthropologists to see transmission of culture where they had before seen independent developments. Hospital war work sent him to psychopathology, and produced *Instinct and the Unconscious* (1920) and *Conflict and Dream* (1923), in which he is seen as a modified Freudian. Willing to apply psychology and scientific method to the solution of political problems, he was about to contest London University constituency as a Labour candidate when he died, 4th June 1922.

Riviera ('seashore'), a term applied to the narrow strip of coast-land bordering the Gulf of Genoa, strictly from Nice to Spezzia, but generally understood to include the whole coast of the department of the Alpes Maritimes, and the Italian coast as far as Leghorn. West of Genoa it is called the Riviera di Ponente, or western coast, and beyond Genoa the Riviera di Levante, or eastern coast. From Hyères to Genoa is 203 miles; from Genoa to Leghorn, 112; sheltered on the north by mountains, the district enjoys an exceptionally favoured climate, no other region north of Palermo and Valencia being so mild in

winter. The western section is the mildest and most frequented. It abounds in the most striking and beautiful scenery, and is planted with numerous health and fashion resorts—Nice, Monaco, Mentone, Ventimiglia, Bordighera, Ospedaletti, San Remo, Alassio, &c.; and west of Nice are Hyères, Fréjus, Cannes, Grasse, Antibes. The various sections of the coast of 'La Provence Maritime' have each certain distinctive peculiarities, but none of them are entirely exempt from occasional cold winds. The Saracens held posts on this coast, and levied blackmail for centuries. The famous *Corniche* (Ital. *Cornice*) road leads along the coast from Nice to Genoa.

Rivière, BRITON, was born in London, 14th August 1840, son of a drawing-master at Cheltenham College, and afterwards at Oxford. His ancestors were French Huguenot refugees. He studied at Cheltenham College, and at Oxford, where he graduated B.A. in 1867. He had exhibited at the Royal Academy as early as 1858, and again in 1864, but from the appearance of 'The Poacher's Nurse' in 1866 he was continuously represented by a succession of pictures, which grew in vigour and impressiveness, in dramatic power, in humour, in pathos, and in technique. As a painter of wild animals he reached the widest popularity through engravings. A.R.A. in 1878, R.A. in 1881, he died 20th April 1920.

Rivingtons. See LONGMANS.

Rivoli, a town of Northern Italy, 8 miles W. of Turin, with two royal castles and some industry. Pop. 9000. It was not near this place, but near Rivoli, 12 miles NW. of Verona, that Napoleon won on 14th and 15th January 1797 one of his most decisive victories over the Austrians.

Riza, a Persian trooper who became war minister in 1921, prime minister in 1923, and on the deposition of the Kajar dynasty, king of Persia in 1925. See PERSIA (*History*).

Rizal, José (1861-96), Filipino writer and organiser, was born, a Tagalog, at Calamba in Luzon, studied medicine in Europe, and wrote Spanish novels (*Noli me tangere*, *El Filibusterismo*) directed against political oppression and the friars. His books were prohibited and he himself banished and shot.

Rizch, a town of Asia Minor, on the coast of the Black Sea, 40 miles E. from Trebizond, manufactures linen and copper utensils; pop. 3000.

Rizzio. See MARY, QUEEN OF SCOTS.

Roach (*Leuciscus rutilus*), a fish of the family Cyprinidae, abundant in England, the south of Scotland, and many countries of Europe. It measures from 10 to 15 inches; the body generally has a silvery appearance, the back is a dull green, the

Roach (*Leuciscus rutilus*).

lower fins are red, and there are no barbels. The roach is gregarious in habit, and large shoals are found usually in lakes, but towards the breeding season they migrate up streams and rivers to spawn. The flesh is white and firm, but without much flavour. For the Blue Roach, see AZURINE.

Road, Rule of. See RULE OF THE ROAD.

Roads form a primary element in the material advancement of a nation, being essential to the development of the country. The condition in which the roads of an old settled country are maintained is a fair indication of the state of industry and trade, and one of the earliest steps in the development of a newly-settled country is the construction of roads.

Historical Sketch.—The Romans were great road-builders, having probably learned the art from the Carthaginians. The highways they constructed were regarded as of vital importance in connection with their military conquests and the maintenance of their world-wide empire. Except when some insuperable natural barrier made it impossible, Roman roads preserved a straight line from point to point, crossing marshes, ravines, and hills which might in many cases have been avoided by moderate deviations. The substantial way in which the Romans built these roads is demonstrated by the fact that they have in some instances borne the traffic of two thousand years without material injury. The plan of construction of these great military roads was generally that adopted in the case of the famous Appian Way (q.v.). The whole empire was ultimately intersected by roads. In Britain there were four main groups of roads radiating from London—one south-easterly through Canterbury to the Kentish ports; a second westerly to Silchester and thence onwards to the south-western districts; a third through St Albans to Chester, afterwards known as Watling Street; a fourth north-easterly through Colchester to Lincoln and York; a fifth road ran diagonally across the country. The roads known respectively by the names Watling Street, Ermine Street, and the Foss Way were not, however, especially important in the Roman system of roads in Britain; in certain cases the Roman roads followed more or less ancient prehistoric lines of communication.

During the Middle Ages these Roman roads, which had up to that time been the only means of internal communication, were allowed to fall out of repair until they became in a worse condition than the roads in most other European countries. In 1285 owners of land were ordered to cut down all trees and shrubs to the distance of 200 feet on either side of the roads between market towns in order to prevent the concealment of robbers in them. In 1346, in the reign of Edward III., the first toll was levied for the repair of some of the roads leading out of London, which were reported to be impassable. In the reign of Henry VIII. an act was passed requiring each parish to elect two surveyors of highways whose duty it was to keep them in repair by compulsory labour; at a later period the 'statute labour-tax' was substituted for compulsory labour. No serious attempt at road maintenance resulted from these enactments, and it was not till the introduction of the turnpike system in the reign of Charles II. that a few of the more important arterial roads were made even passable by vehicles. The deplorable condition of the roads in Great Britain, even at as late a period as 1770, is attested by the description given by Young in his *Six Months' Tour*.

In Scotland between 1726 and 1737 General Wade constructed some 250 miles of roads of 16 to 18 feet width, mainly with the view of opening up the Highlands to trade and of facilitating the pacifying of the country after the 1715 Rebellion.

Modern methods of road-making largely owe their inception to the labours of two Scotsmen—Macadam and Telford—who between them constructed many hundreds of miles of main roads, including such important lines of communication as the Glasgow and Carlisle road and the Shrews-

bury and Holyhead road, this latter involving the erection of the famous Conway and Menai Strait bridges. Macadam originated the idea of putting upon the road 'broken stone which shall unite by its own angles to form a solid hard surface.' His plan was briefly this: after the formation level had been properly drained and levelled, a bed of about 10 inches thick of stone broken to a 2-inch gauge was spread equally over the prepared surface, sufficient convexity being given to the surface in a transverse section to allow rain-water to flow off readily into the side drains. He maintained that the subsoil, if properly drained, would carry without subsidence any weight likely to come upon it from the wheel traffic if protected by his layer of impervious broken stone. His name has been immortalised in the expression 'macadamised roads.' Telford, on the other hand, insisted that a strong foundation of large stones, varying in the case of a roadway of 30 feet width from 9 inches in depth in the centre to 3 inches at the sides, was essential, and upon this foundation a layer about 6 inches thick of smaller broken stone was spread. Telford provided for ample drainage: he realised like Macadam that no road could stand up to its work unless the foundation was kept dry by a carefully-arranged drainage system. Upon these two systems, with various modifications, all modern road construction has been based, though recent developments have more and more emphasised the need of a strong foundation if the road surface is to be kept level and free from distortion.

About 1907 the ever-increasing volume of self-propelled traffic—with speeds and wheel-loads never contemplated by road engineers—focussed public opinion upon the question of road construction and road maintenance. In the year 1908 the first International Road Congress was held in Paris, attended by two thousand delegates from all over the world; and in 1909 a Road Board came into being under the provisions of the Development and Road Improvement Funds Act, 1909. This Board was given powers (a) to make advances to County Councils and other highway bodies in respect of the construction of new roads or the improvement of existing roads, (b) to construct and maintain new roads to facilitate road traffic; its funds consisted of motor-spirit duties and carriage-licence duties. The Board appointed an Advisory Engineering Committee in 1910, and carried out much important work till its activities and funds came to an end at the outbreak of the Great War in 1914; during the four preceding years they made grants amounting to £2,118,045 for improvement of road crusts, widening, and road diversions. The cost of improvement of road crusts had averaged about £1876 per mile of road.

In 1919 approval was given to the Ministry of Transport Act, 1919; under this act a Ministry of Transport was created; under section 2 (c) all powers or duties of any government department with regard to 'roads, bridges and ferries, and vehicles and traffic thereon' were to be transferred to the new Ministry, and under section 22 (1) authority was given to the Minister to appoint a 'Roads Committee' to give advice and assistance in regard to the powers under section 2 (c). Under the provisions of The Roads Act, 1920, which amended previous acts, a fund was established, a 'Road Fund,' derived from licences on mechanically-propelled vehicles imposed by section 13 of the Finance Act, 1920, as amended by this act, and from the excise duties on licences for carriages imposed by section 4 of the Customs and Inland Revenue Act, 1888—all these duties to be levied in future by County Councils and paid by them into the Exchequer. Out of this Road Fund, subject to the prior payment of certain other specified sums,

the Ministry of Transport was authorised to make payments for the purposes of Part II. of the Development and Road Improvement Funds Act of 1909, as amended by this act, the amount to be devoted to the construction of new roads not to exceed in any one year one-third of the estimated amount to be paid into the Road Fund in that year after deduction of the prior payments mentioned above.

The Road Fund receipts have risen from £9,432,302 in 1921 to £16,150,554 in 1925, and the payments from £5,179,375 to £15,234,225, while the balance standing to the credit of the fund on 31st March 1925 was £18,140,386. These figures show what a large sum is now available annually from the Exchequer for road purposes, and how it has been possible to carry out such a big programme of new road construction and to make such a thorough improvement in the roads of this country in such a short period. In the case of roads of Class I. the grants made amount to 50 per cent. of the approved cost, and for roads of Class II. the amount of the grant is 25 per cent. of the approved cost, the total of these two grants for 1924-25 amounting to £9,548,182. Where, as in Scotland, there are roads of these two classes running through sparsely-populated areas and where the highway rates are exceptionally high, grants are made up to 75 per cent. of the approved cost. Another important piece of work made possible by the Road Fund has been the construction of arterial roads in the metropolitan area directly by the Ministry, involving an estimated expenditure of £6,315,000.

The number of motor licences in 1924 was 1,335,600, an increase of nearly 200,000 over the figure for 1923; on the basis of the 1921 census the 1924 licences work out on one motor vehicle for every thirty-two persons in Great Britain. These figures make clear the necessity of the heavy expenditure on road construction and road maintenance which has been so marked a feature of national and local expenditure. The Finance Act of 1926 diverted a portion of the money raised from these licenses by powers conferred by previous Finance acts from the Road Fund to the general revenue of the country.

Road Construction.—In laying out a new road certain general principles have to be kept in mind. Motive power is economised by easy gradients; at the same time it is not desirable to deviate more than is absolutely necessary from the direct route between the fixed points (towns and villages) through which the road must pass. Since excavation and embankment works are expensive, these must be kept as small as possible, and should, as in railway construction, be equalised as much as possible. A careful reconnaissance and survey of two or three trial lines should be made before the route is finally decided upon; this involves also an examination of the geological features of the district and of the beds of streams which have to be crossed by bridges. In fact, the formation of an extended line of road involves generally the construction of bridges, viaducts, and other important works, which require the greatest engineering skill.

In the days of horse-traction the ruling gradient which was permissible was practically fixed by the power which an ordinary team of horses could exert in hauling heavy loaded wagons or coaches. On a level macadamised road in first-rate order the tractive force to move a load of 1 ton varied from about 38 to 45 lb.; on a road of the same nature, with a gradient of 1 in 50, the tractive force would be doubled. As soon as the surface of the roadway deteriorates, the tractive force required rapidly increases, being nearly doubled when the surface is loose and muddy. The kind of material with

which the surface of a road is covered also affects the amount of gradient which can be allowed. For example, an ordinary water-bound macadam road can have a steeper gradient than a roadway covered with asphalt, which becomes under certain climatic conditions very slippery. The steepest gradient allowed in France is 1 in 20, and in the United States the same rule is adopted for important roads; the Road Board suggested that for impervious surfaces of any material the maximum gradient should not exceed 1 in 18. Briefly, every case must be carefully considered, and the engineer must use his own judgment, bearing in mind that horse traffic has still to be provided for, though it is daily becoming a less important factor in road-construction problems. Telford's rule was that 1 in 30 should be the ruling gradient in an important main road, and that rule has been generally maintained in most of the later road-construction work.

What is the best transverse form for a road has been a much-debated question. The only object of 'camber' is to facilitate the rapid flow of rain-water off the road surface into the side drains; much less camber is therefore required in modern roads with their smooth surface than was necessary with the old water-bound macadam roadway; excessive camber is one of the contributory causes to a slippery condition of roadways. On comparatively level roads a fall from crown to side of $\frac{1}{2}$ inch to $\frac{3}{4}$ inch per yard width of road is ample; hence on a 24-foot-wide carriage-way a fall of 3 inches from the crown to the water-chamber at the side is sufficient for drainage purposes; on gradients this camber should be reduced. Whenever the camber is excessive, there is a pronounced tendency for traffic to keep to the crown of the roadway, causing excessive wear on the central part of the carriage-way.

The width of a road has to be fixed by consideration of the volume and character of the traffic which will pass over it; traffic census records have been made by the Ministry of Transport, which indicate a vast increase of traffic since 1914, especially in heavy vehicles; further, while in 1912-13 the horse-drawn traffic was 63 per cent. of the whole, by 1923 it had fallen to 15 per cent.; hence it is obvious that the widths of roads must be fixed now at figures suitable for self-propelled vehicles. A roadway of 24 feet width would provide ample room for three lines of horse-drawn traffic, allowing a width of 8 feet per line; but as the width of many types of motor vehicles is as much as 7 feet 6 inches, involving at least 10 feet of width per line of traffic, a carriage-way of 30 feet for three lines of traffic is now necessary. It must be remembered that motor traffic moves much more rapidly than horse traffic, and that the modern tendency is to use larger goods vans, thus reducing the number of vehicles on the roadway at any one time; both of these factors tend to increase the carrying capacity of a road in relation to its width. In the reconstruction of the Perth-Inverness road a width of 18 feet for the carriage-way has been adopted; on the trunk road from London to Folkestone the carriage-way is to be 30 feet, and the same width has been selected for the new Edinburgh-Glasgow road; this is increased to 40 feet in the city of Edinburgh, and two 30 feet roadways have been provided in the city of Glasgow.

Water-bound macadam will probably still be employed where the traffic is light and the roads pass through sparsely-populated areas, the dust nuisance being overcome by coating the surface with a skin of some bituminous mixture. With a good foundation on the lines of Telford's methods and careful drainage, such roads will last for a long time with but very moderate expenditure on maintenance. The best stone to adopt, and the

size to which it should be broken, require very careful consideration, as the life of the road will depend to a great extent on a wise decision on these two matters. For ordinary work the stone should be broken to a 2-inch gauge; the thickness of the macadam after consolidation by a 10-ton roller should be about 4 inches; the binding material should when it is possible be the same kind of material as the macadam or similar material, not exceeding $\frac{3}{4}$ inch in its greatest dimension. It should be applied only after the macadam has been tightly rolled, being spread evenly over the surface, watered, and then finally rolled. Such roads, in order to keep down the dust nuisance, are tar-sprayed; specially prepared tar should be used, and care must be taken to ascertain that the road surface is absolutely dry to a depth of at least $\frac{1}{2}$ inch below the surface before spraying work is undertaken.

Tar and Bituminous Macadam.—When heavy motor traffic was only a small proportion of the vehicular traffic, ordinary tar-macadam was one of the most commonly used materials for road-construction. The foundation is generally prepared as for water-bound macadam, and the rolled surface of this is floated or flushed with well-boiled tar; the previously prepared tar-macadam is then spread over this foundation to a depth of 4 or 5 inches and rolled, the top-dressing consisting of small stones of about $\frac{3}{4}$ inch gauge; this work should be carried out only in dry weather. To prepare the tar-macadam, good hard stone is broken to the selected gauge, thoroughly dried by heat, and then well-boiled tar is poured over the broken stone, 8 to 12 gallons per cubic yard, the heap being turned over with hot shovels; if not used at once, it must be stored under cover. Instead of tar-macadam, road-engineers now use bituminous macadam, since this material is better able to resist the distortion effects of heavily-laden motor vehicles. Tar-macadam requires a longer time to acquire hardness, and is inclined to be softened by the heat of the sun in summer. In making bituminous macadam the tar is replaced by a bituminous mixture which may contain a percentage of tar, and the macadam may be laid hot. It is a particularly useful coating for old water-bound macadamised roads which require re-surfacing. A first coat of $2\frac{1}{2}$ -inch gauge, followed by a second coat of $1\frac{1}{2}$ -inch gauge, and a surface-coat, which may be an asphaltic composition of $\frac{1}{2}$ to 1 inch in thickness, is good practice; this gives, when rolled, a total thickness of about $3\frac{1}{2}$ inches.

It is necessary to point out that there is some confusion in the nomenclature of bitumen, asphalt, and tars; full information on this matter is contained in a Report of the British Engineering Standards Committee, published in 1918. Tar and pitch are derived from the destructive distillation of hydrocarbon matter, coal, oil, &c. Bitumen is a substance which occurs in nature, or is obtained by the evaporation of asphaltic oils. Asphalt is a road material consisting of a mixture of bitumen and finely-graded mineral matter; rock-asphalt is a rock naturally impregnated with bitumen.

It is impossible to describe in any detail the many systems which have been tried, and the various special road-materials, such as 'tarmac', which have been put upon the market in connection with the construction of bituminous roads; for information on these points, reference must be made to the text books dealing with road-engineering.

Surface Treatment.—For water-bound macadam, tar is the best material; for tar-macadam, a bituminous surface treatment is most satisfactory. In every case the surface to be treated must be brushed free from all dust, and be dry. The better plan of applying the material is by brushing rather than

by any spraying method. Where there is a sound foundation, and the traffic is heavy enough to justify the expense, a surface or carpet of a mixture of bitumen and small chips of granite, clinker, or slag heated and dried forms a fine road-surface; it may be applied in a single thickness of 1 to 1½ inches, or in two coats, the lower coat having larger chips, rolled to about 1 inch thickness, the upper thinner coat having smaller chips, the rolling being done with 10-ton rollers, and continued till the treatment is cold.

Concrete Roads.—The construction of unsurfaced concrete roads has made little advance in this country, and probably never will, except possibly in the case of entirely new roads. In the United States, however, this system of road-construction has been adopted very extensively; by 1921 over 62,000,000 square yards of such roads were in use, and in most cases were proving satisfactory. Where the subsoil is weak, or where the traffic is exceptionally heavy, the concrete should be reinforced with some form of steel wire mesh, placed at about one-third the thickness of the concrete above the bottom of the concrete; the thickness of the concrete may be about 7 inches, and it is advisable to lay it in two layers. One of the chief drawbacks to the use of concrete roads is the comparatively long interval of time that must be allowed to elapse after finishing the road before it is safe to permit traffic upon it, another difficulty is the liability to crack.

Many of the recently-constructed trunk roads in this country have been built upon a reinforced concrete foundation, this foundation being naturally much stronger and more durable against deformation than the older Telford type of broken-stone foundation, though, of course, it is a more expensive class of work. Any of the ordinary types of road-surfacing may be used in conjunction with this form of foundation, which was first adopted for foundations of streets and roads having street tramways.

The construction of paved streets is dealt with under PAVEMENT, but it may be desirable to state that in London and many other large cities, where the vehicular traffic is abnormally heavy and congested, the type of covering over the 7-inch to 10-inch thick concrete foundation which has proved in practice to be the most satisfactory is a 2-inch layer of asphalt. The asphalt used has been mainly the natural carbonaceous limestone found in various localities in France, Tyrol, &c. These pavements fulfil practically every requirement of a first-class roadway except as regards slipperiness. Under certain weather conditions, unless regularly washed down, the asphalt surface is dangerously slippery both for horse traffic and for motor traffic, leading in this latter case to skidding.

In conclusion, it is desirable to emphasise again the necessity of thorough drainage arrangements if a road is to be kept in good order. Except for unimportant country roads, side-ditches are not sufficient; properly constructed side-channels connected to pipe-drains, with suitable sand-traps, are essential, and subsoil drainage must also be provided where the natural soil is damp and liable to become water-logged.

See the following text-books: Aitken, *Road Making and Maintenance*; Boulnois, *Modern Roads*; Wyatt, *Highway Engineer's Year-Book*; Wakelam, *Practical Roadwork*; Blanchard and Browne, *Highway Engineering as presented at Brussels International Road Congress, 1910*; Morrison, *Highway Engineering*; and the publications of the Ministry of Transport (Roads Department); also papers in the *Transactions of the Institution of Civil Engineers*.

Roads in Law.—Roads are included under the general name of highways, a highway being defined as a place over which a right of walking, riding, or

driving is enjoyed by the public generally. Where a Right of Way (q.v.) belongs not to the public generally, but to the owners or occupiers of land or house property, the way in question is private, not public, and the right to use it is classed among Easements (q.v.), or, in Scotland, Servitudes (q.v.). A public way may exist over a place which is not a thoroughfare, as, for example, a street closed at one end. Highways are created by an express or implied grant, whereby the owner of the land dedicates it to the use of the public, by the necessity of things or by act of parliament. If an owner permits the public to pass and repass over his land without interruption, it is presumed that he intends to grant a public right of way; he loses his right to exclude the public, and the way is a highway for ever, unless it should be closed by a public authority under an act of parliament. Public rights may be limited to a particular purpose, as where the inhabitants of a parish have the right to use a way in going to or coming from church. If a highway be out of repair passengers may go over adjacent land; but this is a right to be exercised with caution. Any obstruction placed upon a public way is a nuisance, and may be abated or removed by any person aggrieved. Every part of a highway is equally open to the public; a foot passenger may walk on the carriage-way, and a blind or aged person has as good a legal right to be on the road as any one else. But passengers must use ordinary care to guard themselves against accident, and they must comply with the well-known 'Rules of the Road' (q.v.)—a person driving must keep to the left on meeting another vehicle, and to the right on passing another vehicle; and if he transgresses these rules without justification he will be liable for the consequences. No person is justified in using a highway for any purpose, however useful, which interferes with the general right of the public to pass and repass. Thus it has been held that a local authority cannot lay down tramway lines so constructed as to damage the wheels of carriages using the street, although the tramway might be for the convenience of the public generally. On the same principle it was held an indictable nuisance for a telegraph company to place its posts on a strip of land adjoining the road. Nothing but an act of parliament can legalise such uses of a public way.

Subject to the rights which he has conferred on the public, the owner retains his right of property in the land. If the land on both sides of a highway belongs to the same owner, it is to be presumed that his rights extend over and under the road; if the land on one side belongs to A and on the other side to B, each is presumed to be owner up to the middle line of the way. If, for example, a mine should be opened in the neighbourhood of the road, the adjoining owner or owners would have the right to mine under it, so long as sufficient support is left for the surface of the road. If a gas or water company without authority of parliament takes up a road to lay its pipes, this is not only a nuisance but a trespass, for which damages may be recovered by the owner of the land. It has been held that a person loitering on a highway for the purpose of poaching may be indicted for trespassing on the land of the adjoining owner.

The repair of a carriage-way involves a regular outlay, and there are some cases in which this burden is imposed upon the owner of the land, *ratione tenuræ*, as a part of the service by which he holds his estate. But the general rule of common law is that the inhabitants of a parish must repair the highways within the same; they are liable to indictment if they fail to perform this duty, and no agreement they can enter into will

relieve them of their liability. Many townships, &c., which are not separate poor-law parishes are separate highway parishes by ancient custom. The management of highways separately maintained by the parish was regulated by an act passed in 1835, and amending acts; a parish surveyor was elected by the ratepayers; in parishes over 5000 population a board might be elected. Under an act of 1862 many parishes were grouped in districts. The highway board of a district consisted of waywardens elected for the parishes therein, and of the acting justices who reside in the district. Under the Public Health Act an urban sanitary authority was made the highway authority within its district. Many of the main roads throughout England were constructed or improved under Turnpike trusts, constituted by acts of parliament. Turnpike trusts and highway boards have alike been superseded by the provisions of the Local Government Act of 1878 and subsequent acts. The control of the main roads of a county now rests with the county council, and the burden of their maintenance is a county charge. The rural district councils are the highway authorities for highways other than main roads, and have the powers of the surveyor of highways. In boroughs the powers of the county council are exercised by the corporation. The parish councils take charge of the repair of footpaths. Tolls had been generally abolished before these sweeping changes in road management; see TOLL. See also TRACTION-ENGINES.

The national authority for roads is now the Ministry of Transport, on whom have been conferred the powers in this behalf of every government department, including the Road Board. The Minister of Transport may make advances to county councils and other highway authorities to construct new roads, or to maintain or improve existing ones.

In the law of Scotland a highway is said to be *inter regalia*; but it seems that the presumption is that the land over which a road passes belongs to the adjoining owner or owners. Public rights of way are acquired by actual use for the prescriptive period of forty years. There were formerly two classes of roads—statute-labour and turnpike; by the Roads and Bridges Act, 1878, the management of all roads was vested in county road trustees; by the Local Government Act of 1889 the powers of the road trustees were transferred to the county council; in the burghs they are managed by the town council or the commissioners of police.

For an outline of the English law, see Wright and Hobhouse, *Local Government in England*; for the Scots law, Ferguson, *Roads, Streets and Rights of Way* (1904).

Roanne, a town of France (dept. Loire), 52 miles by rail NW. of Lyons, stands on the left bank of the Loire, which becomes navigable here, and is crossed by a stone bridge (1820). The principal church is St Stephen's (15th to 17th century). Roanne has besides an old castle with antiquarian collections, a modern hôtel-de-ville with a museum, and some manufactures. Pop. (1872) 18,615; (1891) 30,996; (1921) 37,752.

Roanoke, a river of Virginia and North Carolina, formed by the union, a mile above Clarksville, Virginia, of the Pam and Staunton rivers, which rise in the Alleghanies, flows south-east through the north-eastern portion of North Carolina, and empties into Albemarle Sound. It is navigable for steamboats to Weldon (130 miles); its length is 230 miles.

Roanoke, a city of Virginia, on the Roanoke River, 258 miles by rail W. of Norfolk, at a junction of railways. In 1880 a secluded hamlet, by 1890 it was a bustling city, with a court-house,

opera-house, large machine-shops, steel and iron and other works. Pop. (1920) 50,842.

Roaring in horses is a loud sound emitted during the act of inspiration. Whistling is a modification. The cause, in the great majority of cases, is paralysis with wasting, atrophy, and fatty degeneration of the muscles of the larynx, more particularly those of the left side. It often follows catarrh, strangles, or some other disease affecting the respiratory organs; but it is generally concluded that these diseases are not sufficient of themselves to cause it, provided there be no hereditary taint, this hereditary taint alone being sufficient in many instances to induce roaring. There is no certain cure. In 1887 an operation was reintroduced by Dr Fleming. Similar operations had been performed by Günther, in Hanover, so far back as 1834. It consists in making a long incision into the larynx, the animal being under chloroform, and removing the arytenoid cartilage and vocal chord of the paralysed side. Some horses were slightly benefited, but many became worse and had to be destroyed. A somewhat different operation, introduced by Professor Williams of Cornell University, has almost superseded the others. But unfortunately it also often leads to disappointment.

Roaring is now included by the Boards of Agriculture of England and Scotland, and the Royal Agricultural Society of England, among hereditary unsoundnesses.

Roaring Forties, a sailor's term for a region of the great Southern Ocean lying south of 40° S. lat. (especially south of 45°), where the prevailing winds are strong WNW. and NW. winds, often stormy. The same name is sometimes given by analogy to a belt of the North Atlantic about 40°–50° N.

Robben Island (Dutch, 'seal island'), an islet at the entrance of Table Bay, 10 miles NW. of Capetown, about 4 miles long by 2 broad, with great quarries. It contains a leper colony.

Robber Council. See EUTHYCHUS.

Robbery is an aggravated species of larceny. The gist of the offence is that property is taken from the person of some one against his will by force, or by putting him to fear by threats of any kind of injury. The force or terror must be used either before or at the time of the taking of the property; for even the use of actual force, if it does not begin until after the taking, will not make a larceny become a robbery. To constitute the crime the robber must actually obtain possession of the goods; but it does not matter how short the time was during which they were in his possession. The property must be taken from the person, or in the presence of the party robbed. The maximum punishment for robbery is fourteen years' penal servitude. But for robberies that are further aggravated in particular ways (as by the robber being armed with any offensive weapon, or being together with one or more persons) the punishment may be penal servitude for life, and, in the case of a male, whipping—Larceny Act, 1916 (6 and 7 Geo. V., chap. 50), sect. 23 (1). Under this statute, too, even if no article be actually taken and so no robbery be effected, the mere assault with intent to rob is a felony, and punishable with five years' penal servitude. Further, the act (sect. 30) provides that demanding a thing by menaces or by force, with intent to steal it, is a felony punishable with five years' penal servitude. If on an indictment for robbery the jury are of opinion that the accused did not commit robbery, but did commit an assault with intent to rob, they may find him guilty of the latter offence. In Scotland, by the Criminal Procedure Act, 1887 (50 and 51 Vict. chap. 34),

it is now competent, under an indictment for robbery, to convict of reset, or theft, or attempt to rob.

Robbia, LUCA DELLA, sculptor and modeller of figures in relief, was born at Florence in 1399 or 1400, worked all his life there, and died there on 20th February 1482. He designed and executed between 1431 and 1440 ten panels of Angels and Dancing Boys for the cathedral, which Professor J. H. Middleton calls one of the greatest pieces of sculptured work in the 15th century. Another great work by him was a bronze door, with ten panels of figures in relief, for the sacristy of the cathedral, made between 1448 and 1467. In marble he sculptured, in 1457-58, the tomb of Frederighi, Bishop of Piesole (now in the church of San Francesco outside the city). The frame that surrounds this monument is made of exquisitely painted majolica tiles. His name is closely associated with the production of figures in glazed or enamelled terra-cotta, made by a process which, though he did not invent it, he yet improved greatly. Amongst the works he executed by this process are numerous medallions, some white, some polychrome, and reliefs.—His principal pupil was his nephew ANDREA (1435-1525), who worked chiefly at the production of enamelled reliefs, retabes, and medallions, these last for the most part reproductions of the Madonna and Child. Nearly all his works were of religious subjects; they were made chiefly for Florence, Arezzo, and Prato.—His son GIOVANNI (1469-1529?) continued the activity of the family in this style of work; his best productions are the frieze, representing the Seven Works of Mercy, outside a hospital at Pistoja, and a fountain in the sacristy of Sta Maria Novella in Florence.

See Cavallucci and Molinier, *Les Della Robbia* (1884); Leader Scott, *Luca Della Robbia* (1883); Raymond, *Les Della Robbia* (1897); and a number of books by Allan Marquand (1912, &c.); the book on Luca by the Marchesa Burlamacchi (1901); and the larger work on Luca and Andrea by Maud Cruttwell (1903).

Rob Donn. See MACKAY (ROBERT).

Robert I. (OF SCOTLAND). See BRUCE.

Robert II. king of Scotland 1371-90, was born 2d March 1316, two years after the battle of Bannockburn. His father was Walter Stewart (q.v.), his mother Marjory, only daughter of Robert the Bruce; and both parents he lost in infancy. Throughout the disastrous reign of his uncle, David II., he was one of the most prominent of the patriotic nobles of Scotland, twice acting as regent during his exile and captivity, and fighting at Halidon Hill (1333) and Neville's Cross (1346). On David's death (22d February 1371) he obtained the crown, and became the founder of the Stewart dynasty, in virtue of the law of succession settled by the Council of Estates at Ayr in 1315. 'A man not valiant,' Froissart describes him, 'with red blear eyes, who would rather lie still than ride;' and partly from disposition, partly from the infirmities of age, Robert proved a peaceable, if not exactly a pusillanimous ruler. Such wars as were waged with England were not only conducted, but organised, by his powerful and intractable barons, particularly the Earls of Douglas, Mar, March, and Moray, who shaped the policy of the country very much according to their pleasure. The misery inflicted on both sides of the Border by the raids of these warlike chiefs, and the reprisals of the English wardens—the Percies and others—were frightful; famine and pestilence became chronic; but the most celebrated incidents of Robert's reign were the invasions of Scotland by an English military and naval force under the command of the Duke of Lancaster ('old John of Gaunt, time honoured Lancaster') in 1384, and again by King

Richard II. himself in 1385, which wasted the land as far as Edinburgh and Fife, and the grand retaliatory expedition of the Scotch in 1388, which culminated in the battle of Otterburn (q.v.). Robert died at his castle of Dundonald in Ayrshire, 19th April 1390. He married first, in 1349, his mistress, Elizabeth Mure of Rowallan, and secondly, in 1355, Euphemia, daughter of the Earl of Ross and widow of the Earl of Moray.

Robert III., king of Scotland 1390-1406, son of the preceding, was born about 1340. His baptismal name was John, but this name, out of hatred to the memory of John Balliol, was changed on his accession to the throne by an act of the Scottish Estates. His imbecility as a ruler virtually placed the reins of government in the hands of his ambitious brother, Robert, Earl of Menteith and Fife, in 1398 created Duke of Albany, during whose regime the Scottish barons first began to exercise that anarchic and disloyal authority which, in the reigns of the first three Jameses, threatened to destroy the power of the sovereign altogether. The principal events in Robert's reign were the invasion of Scotland in 1400 by Henry IV. of England, who, at the head of a large army, penetrated as far as Edinburgh, but did not inflict much injury on the country—more, however, from clemency than impotence—and the retaliatory expedition of the Scotch, two years after, under Archibald Douglas, which resulted in the terrible disaster at Homildon Hill (q.v.). Robert had two sons, the eldest of whom was David, Duke of Rothesay (1378-1402), a youth not destitute of parts, but shockingly licentious. As long as his mother lived he kept within bounds, compunctively peaking; but after her death, says Buchanan, he gave an unbridled license to his passions; laying aside fear and shame, he not only seduced married ladies and virgins of good family, but those whom he could not entice he forced to his embraces. Albany received orders from the king to act as his guardian, and after a short time starved him to death at Falkland; for which he underwent a mock trial by his own creatures, and was of course declared innocent. Robert now became anxious for the safety of his younger son, James, and, after consulting with Bishop Wardlaw of St Andrews, he resolved to send him to France; but, while proceeding thither, the vessel in which he sailed was intercepted by an English cruiser, and James was taken prisoner. When his father received the melancholy news he gave way to paroxysms of grief, and died 4th April 1406.

Robert of Brunne. See BRUNNE.

Robert of Gloucester. See GLOUCESTER.

Roberts, DAVID, landscape and architectural painter, was born at Edinburgh (in Stockbridge) on 24th October 1796, and was apprenticed to a house-painter. In 1818 he advanced to the grade of scene-painter, and in 1821 went to London to paint scenery for the stage of Drury Lane. All this while he was studying artistic drawing and painting, and in 1826 and 1827 he attracted the attention of the public with pictures of Rouen and Amiens cathedrals in the Royal Academy exhibitions. Then for several years he travelled in Spain, Morocco, Egypt, Palestine, Italy, Belgium, making drawings of grand and impressive buildings and landscapes with picturesque edifices, and working them up into pictures. From among this work the following stand out—the drawings from Spain for the illustrations to the *Landscape Annual* (1835-38); the magnificent volumes of *The Holy Land*, *Syria*, *Idumea*, *Arabia*, *Egypt*, and *Nubia* (1842); numerous interiors of churches, as St Miguel at Xeres, Holy Nativity at Bethlehem, St Jean at Caen, St Paul at Antwerp, St Peter's at Rome,

the cathedrals of Milan and Seville; and the grandiose pictures, 'Departure of the Israelites from Egypt' (1829), 'Ruins of the Great Temple at Carnac' (1845), 'Jerusalem from the South-east' (1845), 'Destruction of Jerusalem' (1849), 'Rome, (1855), and 'Grand Canal at Venice' (1856). Roberts's style is essentially spectacular, producing grand broad effects, with magnificent architectural arrangements, to which the details are of course generally sacrificed. He was elected an A.R.A. in 1839, an R.A. in 1841; and died 25th November 1864. See *Life* by James Ballantine (1866).

Roberts, Frederick Sleigh Roberts, Earl, was born at Cawnpore, 30th September 1832, the son of General Sir Abraham Roberts. He was brought to England when two years old, educated at Clifton, Eton, Sandhurst, and Addiscombe, and entered the Bengal artillery in 1851. His first taste of actual warfare was got in the hot time of the siege of Delhi, during the Mutiny, and he took an active part in the subsequent operations down to the relief of Lucknow, acting on the staff, in the quartermaster-general's department, and he won the V.C. He discharged the duties of assistant quartermaster-general in the Abyssinian expedition of 1868, and in the Lushai expedition of 1871-72. On the outbreak of the Afghan war in 1878, Roberts, now major-general, was appointed to command the Kurram division of the army. He forced in brilliant fashion the Afghan position on the peak of Pelwur Kotul (8500 feet above sea-level), and was rewarded with a knight-commandership of the Bath (1879). After the murder of Sir Louis Cavagnari and the escort of the British mission at Kabul, he was given the command of the force sent to avenge them. He defeated the Afghans at Charásin on 6th October, took possession of Kabul on the 12th, and assumed the government of the country, Yákiúb Khan having abdicated. Events followed quickly: the fortified cantonment of Sherpur was occupied by the British army, the fortress of Bala Hissar in Kabul was dismantled, Yákiúb Khan was sent a prisoner to India, the Afghans began to concentrate on Kabul, General Roberts sought to check them, and there was much sharp fighting round the city, Abdul Rulman was proclaimed Amir, and General Burrows was crushingly defeated at Maiwand, and the British garrison of Kandahar besieged by the followers of Ayub Khan. On 9th August Sir F. Roberts set out with 10,148 troops, 8143 native followers, and 11,224 baggage animals on his memorable march through the heart of Afghanistan to the relief of Kandahar, which he reached three weeks later. He immediately gave battle to Ayub Khan, and routed him completely, capturing all his artillery and his camp. When he visited England towards the close of the year he was honoured with a baronetcy, and on his return to India was appointed commander-in-chief of the Madras army (1881), and from 1885 till he resigned the post in 1893, held the rank of commander-in-chief in India. In 1895 he was made Field-marshal and Commander of the Forces in Ireland. In December 1899 he was sent to South Africa to take chief command in the Transvaal War, with Lord Kitchener (q.v.) as chief of his staff. Here he had eventually nearly 200,000 men under his command, the largest British army that had ever engaged in any war. After a brilliant series of engagements (capturing Commandant Cronje and 4000 men) he occupied Bloemfontein and hoisted the British flag in Pretoria (5th June 1900); and the South African Republic and the Orange Free State were proclaimed British colonies. In December 1900 he returned to England, and was commander-in-chief till the office was abolished in 1904. He strenuously insisted on the necessity of universal military service for the safety of Britain, as set

forth in *Fallacies and Facts* (1911). He died, 14th November 1914, at the headquarters of the British Army in France, whither he had gone to visit the Indian troops. He had been made a baron in 1892, an earl in 1901. See his own *Forty-one Years in India* (1896), and his *Letters written during the Indian Mutiny* (1924). He wrote also *The Rise of Wellington* (1895).

Roberts, Morley, born at London in 1857, a son of an income-tax inspector, studied at Owens College, went to Australia in 1876, and after an adventurous life as railwayman, cattle-tender, and seaman in Australia, the United States, and Canada, with intervals of work in public offices, made himself known by a long series of novels. *The Private Life of Henry Maitland* (1912) is the sad story of George Gissing's life.

Robertson, Alexander (1668-1749), of Strouan, a Perthshire laird and irreconcilable Jacobite, who was 'out' in almost every rebellion from 1689 to 1745, was reckoned a poet on the strength of poor verses of some historic interest.

Robertson, Frederick William, was born, eldest of the seven children of an artillery captain, in London on 3d February 1816, and spent his first five years at Leith Fort. He went to school at Beverley, Tours, and Edinburgh, was in a solicitor's office, qualified for an army commission, but after much misgiving, persuaded of his vocation for the church, went to Brasenose, Oxford, in 1837. Ordained in 1840, he held a curacy at Winchester for a year, fell into ill-health, recovered, and married. In 1842 he became curate to the incumbent of Christ Church, Cheltenham, and here for nearly five years he laboured with unbroken devotion, and, despite depression of spirits, fought his way to certainty in his grasp of Christian truth, his faith in Evangelicalism being shaken by the intolerance of its partisans. In 1846, after three months of travel and preaching at Heidelberg, he returned a follower of no school to accept the curacy of St Elbe's in Oxford. The power of his preaching had already made itself felt among his poor and even among the undergraduates, when in 1847 he accepted an invitation to Trinity Chapel, Brighton. There his rare union of imaginative with dialectic power, the beauty and freshness of his thought, his earnestness, originality, wide sympathy, and knowledge of the human heart at once arrested public attention. He established the Working-men's Institute there, and flung himself with a passionate and chivalrous enthusiasm into every battle waged in his day against tyranny and wrong. He himself summed up the cardinal principles of his teaching under these heads: (1) The establishment of positive truth, instead of the negative destruction of error; (2) That truth is made up of two opposite propositions, and not found in a *via media* between the two; (3) That spiritual truth is discerned by the spirit, instead of intellectually in propositions; and therefore truth should be taught suggestively, not dogmatically; (4) That belief in the human character of Christ's humanity must be antecedent to belief in his divine origin; (5) That Christianity, as its teachers showed, works from the inward to the outward, and not *vice versa*; (6) The soul of goodness in things evil. He resigned in June 1853 because the vicar of Brighton had refused to confirm his nomination of a curate, and died two months later. He published but one sermon—the five series (1855-90) so called are really recollections in abbreviated form. Expository lectures on the Epistle to the Corinthians (1859) and notes on *Genesis* (1877) were printed, and a volume of *Lectures and Addresses* (1858), reissued with additions as *Literary Remains* (1876). He translated

Lessing's *Education of the Human Race* (1858), and prepared an admirable analysis of *In Memoriam* (1862). His letters are hardly inferior to his sermons in charm and power; and the *Life and Letters* by Stopford Brooke (1865) at once took a place amongst classic English biographies.

Robertson, GEORGE CROOM (1842-92), born at Aberdeen, studied at Aberdeen under Professor Alexander Bain (q.v.), from whom his philosophical system derived its main impulse. He continued his studies at University College, London, as well as in France and Germany; and in 1866 became professor of Mental Philosophy and Logic at University College, London. He wrote on Hobbes, and started (1876) and edited *Mind*. See memoir by Professor Bain prefixed to his *Philosophical Remains* (1894). Two volumes of lectures were also published from notes by Mr Rhys Davids, as *Elements of General Philosophy and Elements of Psychology* (1896). His general position was akin to that of Bain and the two Mills.

Robertson, JAMES, (1725-88), born in Fifeshire, served in America in the French and Indian wars, and then in the British army in the Revolutionary war, being (in 1779), when major, made governor of New York. He was regarded as arbitrary and unscrupulous.

Robertson, JAMES CRAIGIE (1813-82), born at Aberdeen, studied at Trinity College, Cambridge, and became vicar of Bekebourne, Kent (1816), canon of Canterbury (1839), and professor of Ecclesiastical History at King's College, London (1864-74). His chief work was *Materials for the History of Becket* (6 vols. Rolls series, 1875-82); but he wrote also a *History of the Christian Church* and lectures on the growth of the papal power.

Robertson, JOSEPH, Scottish antiquary, was born, a small shopkeeper's son, at Aberdeen, 17th May 1810, and was educated at Olney Academy, and the grammar-school and Marischal College of his native city. An Episcopalian and Conservative, he was apprenticed to a lawyer, but took early to writing, and, after six years of literary work at Edinburgh, was a newspaper editor at Aberdeen, Glasgow, and Edinburgh from 1839 to 1853. He was in that year appointed errand of the historical department of the Edinburgh Register House, and died 13th December 1866. He was an originator of the Aberdeen Spalding Club (1839-70), for which he edited four works; and for the first edition of this encyclopaedia he wrote eighty articles. Of his other works may be noticed *The Book of Bona Accord, or a Guide to the City of Aberdeen* (1839), *Catalogues of the Jewels, Dresses, Books, and Paintings of Mary Queen of Scots* (Bannatyne Club, 1863), the invaluable *Concordia Scotica: Ecclesiae Scotiae Statuta, 1225-1559* (2 vols. Bannatyne Club, 1866), and an admirable article in the *Quarterly Review* for June 1849 on 'Scottish Abbeys and Cathedrals.' See the Memoir prefixed to a reprint of the last (Aberdeen, 1891).

Robertson, THOMAS WILLIAM, dramatist, was born at Newark-on-Trent, on 9th January 1829, of a family of actors. About the middle of the century the Lincoln circuit, with which his father was connected, ceased to pay; the company was broken up, and 'Tom' proceeded to London. There he struggled for a living, acting as prompter and stage manager, writing unsuccessful plays, acting himself, writing for newspapers and magazines, *Fun* amongst them, translating French plays, and so forth; but Robertson was never an actor of any mark. His first success as a dramatist was with *David Garrick*, in 1864, the title rôle of which was one of Sothorn's great things. This was followed by the production of the comedy *Society* (1865) at Liverpool, where, as later in

London, it was received with the warmest approval. His next comedy, *Ours* (1866), produced by the Bancrofts at the Prince of Wales's Theatre, London, thoroughly established Robertson's fame; and from that time his pen was kept incessantly busy. *Caste* (1867), *Play* (1868), *School* (1869), *M.P.* (1870)—all brought out by the Kendals at the Prince of Wales's—and *Home* (1869) and *Dreams* (1869), the former at the Haymarket, the latter at the Gaiety, were all equally successful. But in the midst of his triumphs Tom Robertson died, in London, on 3d February 1871. His best comedies long retained their popularity owing to the excellence of their construction and stagecraft, their bright and merry humour, their wholesome, healthy tone, their happy contrasts, and the sunny spirit that shone through them. See his *Principal Dramatic Works*, with Memoir by his son (2 vols. 1889), and the *Life and Writings*, by Pemberton (1893).

Robertson, WILLIAM, the historian, was born 19th September 1721, at Borthwick in Midlothian, of which parish his father was minister. He went to school at Dalkeith, at twelve entered the university of Edinburgh, and at twenty-two was ordained as minister of Gladsmuir. On the sudden death of his father and mother soon after, the care of a younger brother and six sisters devolved upon him, and this duty he at once cheerfully undertook, although his income was but £100 a year. At the same time he was assiduous in preaching, in catechising, and in all the duties of his office. His vigour and patriotism he showed by joining a body of volunteers formed for the defence of Edinburgh against the Jacobite rebels in 1745, and after the surrender of the city he offered his services to the commander at Haddington. As early as 1751 we find Robertson taking a prominent part in the debates of the General Assembly, and indeed his influence soon became supreme as leader of the 'Moderate' party in the church. He carried the deposition of Gillespie in the Assembly in 1752, and in 1757 the acquittal of Carlyle of Inveresk before the Synod for having been present at the performance of Home's tragedy of *Douglas* on the Edinburgh stage. From 1759 till his death he was joint-minister with Dr Erskine of Greyfriars Church, Edinburgh, and in the same year he was appointed chaplain of Stirling Castle. Still further, in 1761 he became a royal chaplain, in 1762 principal of the university of Edinburgh, and in 1764 the office of king's historiographer was revived in his favour, with a salary of £200 a year. Tempting offers of golden preferment in the English church were held out to him, but these he was too sensible and honest to accept. All this was because of the splendid and immediate success of his *History of Scotland* (1753-59), which earned the warmest praises from Hume, Horace Walpole, Lord Chesterfield, Bishop Warburton, David Garrick, and Baron d'Holbach, if not Dr Johnson—'Sir, I love Robertson; and I won't talk of his book,' said the doctor to Boswell. Next followed the *History of the Reign of the Emperor Charles V.* (3 vols. 1769), to which was prefixed an admirably synthetic and suggestive *View of the State of Society in Europe from the subversion of the Roman Empire to the beginning of the Sixteenth Century*. He received £4500 for the copyright, and was gratified by the most flattering praises from Voltaire and Gibbon. The *History of America* appeared in 1777; *An Historical Disquisition concerning the Knowledge which the Ancients had of India* in 1791. Robertson died near Edinburgh, 11th June 1793, and was buried in the Greyfriars churchyard.

Robertson's Histories are still excellent reading, although in every case they have been left behind by the more valuable works of a later day. Their merit is great, considering the slenderness of the

materials then available and the fact that he lived almost half a century before the modern conception of the scope and method of history awoke. None of his contemporaries philosophised on defective data with greater dignity or less unconsciousness of 18th-century limitations; but it is true that many of the remarks in his review of the state of Europe display a quite remarkable sagacity and power of generalisation. His style is clear and correct, but is formal, and lacks idiomatic vigour and spontaneity.

See short lives by Dugald Stewart, prefixed to his works, and by Bishop Glegg; also the sketch by Lord Brougham (a grand-nephew) in his *Lives of Men of Letters of the Time of George III.*; 'Jupiter' Carlyle's *Autobiography*, and Cockburn's *Memorials*

Robes, MISTRESS OF THE. See HOUSEHOLD.

Robespierre, MAXIMILIEN MARIE ISIDORE, was born of a legal family, originally of Irish origin, at Arras, 6th May 1758. His mother died in 1767, his broken-hearted father two years later, and the four children were brought up by their maternal grandfather, an Arras brewer. Maximilien, the eldest, early showed unusual promise, and was educated at Arras and at the Collège Louis-le-Grand at Paris, where Camille Desmoulins was a fellow-student. He was admitted *avocat* in 1781, and next year was named criminal judge by the bishop of Arras, but resigned his place soon after to avoid passing a sentence of death. All through life a fanatical devotee of the gospel according to Rousseau, his sentimentality and taste for verses made him popular among the *Rosati* at Arras. He drew up the *caduc* or list of grievances for the guild of cobblers, and was elected to the States-general in 1789 as one of the deputies for the *tiers état* of Artois. He soon attached himself to the extreme Left—the 'thirty voices,' and though his first speeches excited ridicule, it was not long before his earnestness and his high-sounding phrases commanded attention. 'That young man believes what he says; he will go far,' said Mirabeau, forecasting his future with the divination of genius. Indeed his influence grew daily, both in the Jacobin Club and in the Assembly, and thousands amongst the mob of patriots outside became fanatical in their admiration of his sincere cant and his boasted incorruptibility. Three days after the death of Mirabeau he called upon the Assembly to prevent any deputy from taking office as minister for four years, and in the following month (May 1791) carried the motion that no member of the present Assembly should be eligible for the next. This policy grew out of the narrow and acid suspiciousness of his own nature, and reveals the inherent meanness of his aims and his failure to grasp that grand idea of real parliamentary government by a responsible ministry, which had been the dearest dream of Mirabeau. Next followed Robespierre's appointment as public accuser, the king's flight to Varennes (June 21st), Lafayette's last effort to control the sacred right of insurrection on the Champ-de-Mars (17th July), the abject terror of Robespierre, his sheltering himself in the house of Duplay, a carpenter, his hysterical appeal to the Club, the theatrical oath taken by every member to defend his life, and his being crowned with chaplets, along with Pétion, and carried home in triumph by the mob at the close of the Constituent Assembly (30th September).

After seven weeks of quiet he sold his small patrimony and returned to Paris, to the house of Duplay, where he remained to the last day of his life. He was much beloved in the family, and a passion quickly sprung up betwixt himself and his host's eldest daughter Eléonore, a romantic girl of twenty-five. His room was a humble chamber

in which he worked and slept; its decorations, a few busts and portraits of himself. Alone amongst the patriots he was noted for the carefulness of his dress, which never varied in the slightest—powdered hair, a bright blue coat, white waistcoat, short yellow breeches, with white stockings and shoes with silver buckles. Small and feeble in frame, solitary and reserved in habits, he ever wore an anxious look upon his straitened and spectacled face; his complexion was atrabilious, even *verdâtre*; and he retained to the last the sobriety of the cynic, drinking only water.

Meantime the Girondist party had been formed in the new Legislative Assembly, its leaders—the loudest, Brissot—eager for war. Robespierre, who ever feared and disliked war, offered a strenuous opposition in the debates of the Jacobin Club, and sometimes, if seldom, in his endless and windy harangues rose into the region of real eloquence. He headed the Jacobin wing of 'the Mountain'—the party in the Assembly which, sitting on the higher benches, opposed the Girondists—as Danton headed the Cordelier wing. In April 1792 he resigned his post of public prosecutor. He was invisible during the crisis of the 10th August, but he joined the Hôtel-de-Ville faction, and on the 16th August we find him presenting to the Legislative Assembly its petition for a Revolutionary Tribunal and a new Convention. It does not appear, however, that he was in any sense directly responsible for the atrocious September massacres in the prisons, or more than a mere accessory after the fact. For his reward he was elected first deputy for Paris to the National Convention, which opened on the 21st September. The bitter attacks upon him by the Girondists were renewed only to throw Robespierre into a closer union with Danton and his party, but the final struggle was interrupted for a little by the momentous question of the king's trial. Robespierre opposed vigorously the Girondist idea of a special appeal to the people on the king's death, and his execution (21st January 1793) opened up the final stage of the struggle, which ended in a complete triumph of the Jacobins on the 2d June of the same year. The first Committee of Public Safety—a permanent Cabinet of Revolution—was decreed in April 1793, but Robespierre was not elected till the 27th July. He was now for the first time one of the actual rulers of France, but it is open to question whether for the whole twelve months from this time to the end he was not merely the stalking-horse for the more resolute party within the Twelve. His vaunted respectability, his great popularity with the mob, and his gift of fluent, if vague and windy, oratory made an admirable cover for the truculent designs of strong and completely unscrupulous men like Billaud-Varennes and Collot d'Herbois, and at least it is certainly the case that Couthon and Saint-Just were the only members whose political and social ideals coincided with his own. Destitute of political intuition, without foresight or sagacity, himself the mere dupe of a few borrowed phrases, he was strong because within his narrow limits he was honest, and because he actually had a horizon of social ideals, not nakedly identical with his own advantage. He was astute enough, moreover, to play off one force against another—the Convention, the Commune, and the Committee, while he derived his strength from the constant worship of the Club.

The next scenes in the great drama of Revolution were the dark intrigues and desperate struggles that sent Hébert and his friends to the scaffold on the 24th March 1794, and Danton and Robespierre's school-fellow, Camille Desmoulins, on the 6th of April after. Hébert Robespierre had

long disliked, and Chaumette's crazy deification of the Goddess of Reason had filled him with disgust; Danton he at once hated and feared with that fierce and spiteful hatred he ever felt instinctively for men like the great Tribune and Vergniaud with natural gifts beyond his own. 'Robespierre will follow me: I drag down Robespierre,' said Danton with prophetic truth. The next three months he reigned supreme, but his supremacy prepared the way for his inevitable fall. He nominated all the members of the Government Committees, placed his creatures in all places of influence in the commune of Paris, sent his henchman Saint-Just on a mission to the armies on the frontier, assumed supreme control of the Revolutionary Tribunal, and completely revolutionised its method of operation by the atrocious measure introduced by his creature Couthon on the 22d Prairial (10th June), to the effect that neither council nor witnesses need be heard if the jury had come otherwise to a conclusion. The fatal significance of this change—a complete abrogation of all law—is seen in the fact that from this time till the day of Robespierre's death the daily tale of victims of the guillotine averaged almost thirty. But, in accordance with the law that governs all human things, as Robespierre's power increased his popularity decreased, and still further he had committed the fatal folly of making himself publicly ridiculous. Already his voluntary bodyguard of *Tappe-dars* had excited division and resentment, but his declaration on 7th May of a new religion for the state—the foundation of a new regime of public morality—awakened in the mind of Paris the slumbering sense of humour. The Convention at Robespierre's instance agreed to compliment the Supreme Being with an acknowledgment of His existence and themselves with the Consolatory Principle of the Immortality of the Soul, to be celebrated in thirty-six annual festivals. The first of these was held on the 8th of June, when Robespierre, glorious in a new violet-blue coat, walked in front of the procession and delivered his soul of a vapid harangue, and set fire to paste-board figures representing Atheism, Selfishness, Annihilation, Crime, and Vice. An old mad woman named Catherine Theot, who thought herself the mother of God, now deified Robespierre to be the new divine Saviour of the world, and drew down upon him still further ridicule in the Convention. Meantime the pace of the guillotine grew faster, although apparently Robespierre hoped to bring it to a close as soon as all his more dangerous enemies, like Tallien, Fouché, and Vadier, were cut off. Meantime the public finance and the work of government generally drifted to ruin, and Saint-Just openly demanded the creation of a Dictatorship in the person of Robespierre as alone possessing intellect, energy, patriotism, and revolutionary experience enough. On the 26th July (8th Thermidor), after about a month's absence, the Dictator delivered a long harangue complaining that he was being accused of crimes unjustly. He was listened to in deep and unsympathetic silence, and the Convention, after at first obediently passing his decrees, next rescinded them and rejected his proposals to the committees, and the sitting ended without anything being concluded. That night at the Jacobin Club his party again triumphed, and the Tallien party in despair hurried to the members of the Right, the Girondist remnant, and implored their help against the common enemy at this desperate juncture. Next day at the Convention Saint-Just could not obtain a hearing. Tallien, Billard-Varennes, and Vadier vehemently attacked Robespierre, and the voice of the Dictator himself was drowned with cries of 'Down with the tyrant!' Turning to the Right, 'I appeal to you whose hands are clean,' he cried, but the Right sat

in stony silence. 'President of Assassins, I demand to be heard,' he cried, but his voice died down in his throat.—'The blood of Danton chokes him,' cried Garnier. An unknown deputy named Louchet proposed that Robespierre should be arrested, and at the fatal words his power crumbled into ruins. His younger brother and Lebas demanded to be included in the honourable sentence. Vain attempts were made by the Jacobin Club and the Commune to save their hero, but Paris refused to move, and even Hemiot's artillerymen to obey. Robespierre broke his arrest and flew to the Common Hall, whereupon the Convention at once declared him out of the law. The National Guard under Barras turned out to protect the Convention, and Robespierre had his lower jaw broken by a shot fired by a gendarme named Merda, or, as many believed, by his own hand. Next day (28th July; 10th Thermidor 1794), still in his sky-blue coat, the miserable, trembling wretch died with Saint-Just, Couthon, and nineteen others by the guillotine; the day after seventy-one members of the municipality followed, twelve more on the third day, and the Reign of Terror was extinguished in a sea of blood.

See the histories of the Revolution by Lamartine, Michelet, Louis Blanc, Carlyle, Von Sybel, H. Morse Stephens, and M. Taine; the Life by G. H. Lewes (1849); Hamel's exhaustive but too eulogistic *Vie de Robespierre* (3 vols. 1865-67), also his *Thermidor* (1891); Hilaire Belloc's *Robespierre* (1902); Clauzel's (1912); and Warwick's *Robespierre and the French Revolution* (1909).

Robin. See REDBREAST. The American Robin is a thrush—the *Turdus migratorius*; and the Golden Robin is the Baltimore Bird (q.v.).

Robin Goodfellow. See PUCK.

Robin Hood, the hero of a group of old English ballads, represented as an outlaw and a robber, but of a gallant and generous nature, whose familiar haunts are the forests of Sherwood and Barnsdale, where he fleets the time carelessly in the merry greenwood. He is ever genial and good-natured, religious, respectful to the Virgin and to all women for her sake, with a kind of gracious and noble dignity in his bearing. He lives by the king's deer, although personally most loyal, and wages ceaseless warfare on all proud bishops, abbots, and knights, taking of their superfluity, and giving liberally to the poor and to all honest men in distress, of whatever degree. He is unrivalled with the bow and quarter-staff; but in as many as eight of the extant ballads comes off the worse in the combat with some stout fellow, whom he thereupon induces to join his company. His chief comrades are Little John, Scutthok (Scarlet), and Much; to these the *Gest* adds Gilbert of the White Hand and Reynold. A stalwart curial friar, called Friar Tuck in the title though not in the ballad, fights with Robin Hood, and apparently accepts the invitation to join his company, as he appears later in two broadsides, which also mention Maid Marian. Such is the romantic figure of the greatest of English popular heroes—a kind of yeoman-counterpart to the knightly Arthur.

The earliest notice of Robin Hood yet found is that pointed out by Percy in *Piers Plowman*, which, according to Skeat, cannot be older than about 1377. Here Sloth says in his shrift that, though but little acquainted with his paternoster, he knows 'rymes of Robyn Hood and Landolf, erle of Chestre.' In the next century we find him mentioned in Wyntoun's *Chronicle of Scotland* (c. 1420); a petition to parliament in the year 1430 represents a broken man in Derbyshire taking to the woods 'like as it hadde be Robyn-hode and his meyn'; Bower, in his *Scotichronicon* (1441-47), describes the lower orders of his time as entertaining themselves with ballads both merry and serious

about Robin Hood, Little John, and their mates, and preferring them to all others; and Major or Mair (c. 1470-1550) says in his *Historia Maioris Britannie* that Robin Hood ballads were sung all over Britain. The last passage gives apparently the earliest mention of those more romantic and redeeming features of Robin Hood which earned him a place in Fuller's *Worthies of England*, under his proper county, sweet Nottinghamshire, 'not for his thievery but for his gentleness.' Yet another 15th-century mention occurs in the *Paston Letters*, where Sir John Paston writes in 1473 of a servant whom he had kept to play Robin Hood and the Sheriff of Nottingham.

Fragments of two Robin Hood plays exist, one dating from 1475, the other printed by Copland with the *Gest* about 1550. The latter is described in the title as 'very proper to be played in May-games.' Robin Hood was a popular figure in these during the 16th century, as we find from Stow, Hall, and other writers, and there is evidence that in this connection he was known as far north as Aberdeen. In place-names again we find traces of him in cairns, mounds, hills, rocks, crosses, fountains, caves, and oaks from Somerset to Whithy. In the *Gest* the localities around Barnsdale are topographically correct, down to the place of his death at the priory of Kirkless between Wakefield and Halifax. Here the valiant outlaw is touchingly bled to death by his kinswoman the prioress, to whom he had gone for relief in his sickness. His last charge to Little John is completely true to his character, and is expressed in lines of touching simplicity:

Lay me a green sod under my head,
And another at my feet;
And lay my bent bow by my side,
Which was my music sweet,
And make my grave of gravel and green,
Which is most right and meet.

There is no evidence worth anything that Robin Hood was ever more than a mere creation of the popular imagination, but in due time the yeoman became a political personage, and was transformed into an Earl of Huntingdon for whom a suitable pedigree was constructed. Both Sir Walter Scott, in *Ivanhoe*, and Thierry, in his *Conquêtes de l'Angleterre*, make him a Saxon chief holding out like Hereward against the Normans; Bower, the continuator of Fordun, distinctly calls him one of the proscribed followers of Simon de Montfort; Joseph Hunter (1852) makes him an adherent of the Earl of Lancaster in the insurrection of 1322. The last scholar discovered a still further and exceptionally amusing mare's nest in the name of one Robyn Hode, who entered the service of King Edward II. about Christmas 1323 as one of the 'valets, porteurs de la chambre,' and was eleven months later found unfit for his duties, and paid off with a gift of five shillings. 'To detect "a remarkable coincidence between the ballad and the record" requires,' says Professor Child, 'not only a theoretical prepossession, but an uncommon insensibility to the ludicrous.' Kuhn again identifies our outlaw with Woden; others with a sun-god, a woodland deity, and the like—all which subtleties of speculation are unnecessary if we readily admit that the hero of popular creative imagination may well have formed a peg round which to hang much old-world lore even then fast fading into forgetfulness.

Of Robin Hood ballads there have come down to us in more or less ancient form as many as forty, of which eight may be said to be of the first importance, and of almost the finest quality of ballad poetry. Of the remaining thirty-two, as Professor Child points out, about half a dozen have in them something of the old popular quality; as many more not the least snatch of it. Fully a dozen

are variations, sometimes wearisome, sometimes sickening, upon the theme 'Robin Hood met with his Match.' The best of all the cycle are perhaps 'Robin Hood and the Monk,' and 'Robin Hood and Guy of Gisborne,' and both open with a delightful glimpse of the green wood a century and more before its time in English poetry—

In somer, when the shawes be sheyne,
And lewes be large and long,
Hit is full mery in ley re foreste
To here the foulis song :

To se the dere draw to the dale,
And leve the hilles hee,
And shadow hem in the levis grene,
Under the grene-woode tre.

The second begins no less heartfully—

When shawes becom sheene, and shirads full fayre,
And lewes both large and longe,
Hit is mery, walking in the faye forest,
To hear the small birds song.

The *Lyttell Geste of Robyn Hode* was printed by Wynken de Woide, most probably before 1500, a long poem of over 1800 lines, arranged in eight *fyttes*, being a not unskillful redaction of at least four earlier distinct ballads.

See Lettice's collection of Robin Hood ballads (2 vols. 1735); J. M. Gatch's *Lyttell geste of Robyn Hode* (2 vols. 1847); the *Percy Folio Manuscript*, vol. i. (1867), and the Introduction to the Robin Hood ballads there by Professor Hales; and especially part v. (Boston, 1888) of Professor Child's magisterial *English and Scottish Popular ballads*. The first known 'Garland' was printed in 1670, and in 1678 there appeared a prose version of it, reprinted by Thomas in his *Early English Prose Romances*. See also BALLADS; and Sidney Lee in *Dict. Nat. Biog.*

Robin Hood's Bay, a fishing-village in the North Riding of Yorkshire, 6½ miles S.E. of Whithy. The bay itself is picturesquely fringed by lofty cliffs, rising in the Old Peak, its southern horn, to a height of 585 feet. It owes its name to traditions of Robin Hood, whose arrows shot from the tower of Whithy Priory reached Hawsker, 3 miles distant.

Robinia, a genus of trees and shrubs of the family Leguminosae, sub-family Papilionaceae. The most important species is the Locust Tree (q.v.), also known as the False Acacia, or Thorn Acacia, often simply designated *Acacia*. It is a native of North America, extending from Canada to the southern states, and is there much valued for the hardness and durability of its timber. With it, it is alleged, the houses of the Pilgrim Fathers were built, and the city of Boston founded. When green it is of soft texture, but when mature and seasoned it rivals the oak for strength and durability. It is close grained and finely veined, and in America is the most valued of all timbers for cabinet-work. On account of its quick growth, its spines, and its property of submitting to be clipped into any form, it is very suitable for hedges. In the south of Europe it succeeds well as a timber-tree, but in more northern regions it suffers from frost in severe winters; and in Britain it often suffers from frost, owing to the imperfect ripening of the wood in summer. It does not readily rot in water, and has been used for shipbuilding. The tree is very ornamental, and of rapid growth. The flowers are fragrant and white, in large pendulous racemes. In San Domingo its flowers are used for making a distilled liquor and a syrup. The roots throw up many suckers, and are very sweet, affording an extract resembling liquorice.—*R. viscosa* is a smaller tree, but even more ornamental, a native of the south western parts of the Alleghany Mountains. It has rose-coloured scentless flowers. The young branches are viscid.—The Rose Acacia (*R. hispida*) is a native of the south-western ranges of the Alleghany, and is a highly ornamental shrub, with hispid branches, and large rose-coloured scentless flowers.

Robins, BENJAMIN, mathematician, the father of the military art of gunnery, was born at Bath in 1707 of a poor Quaker family. Having obtained a little instruction in mathematics, he prosecuted this branch of science with great zest, and, having removed to London, set up for a teacher of mathematics, and published several mathematical treatises which gained for him considerable reputation. Robins next commenced his great series of experiments on the resisting force of the air to projectiles, varying his labours by the study of fortification, and invented the Ballistic Pendulum. In 1735 he demolished, in a treatise entitled *A Discourse concerning the Certainty of Sir I. Newton's Method of Fluxions*, Berkeley's objections against Newton's principle of ultimate ratios. His great and valuable work, the *New Principles of Gunnery*, upon the preparation of which he had spent an enormous amount of labour, appeared in 1742, and produced a complete revolution in the art of gunnery. In consideration of his able defence of the policy of the government, by means of pamphlets which he wrote and published from time to time, he received (1749) the post of 'Engineer-in-general to the East India Company'; but his first undertaking, the planning of the defences of Madras, was no sooner accomplished than he was seized with a fever, and he died July 29, 1751. His works were collected and published in 1761.

Robinson, EDWARD, philologist and biblical scholar, was born at Southington, Connecticut, April 10, 1794, graduated at Hamilton College, New York, in 1816, and there remained till 1821, when he went to Andover, Massachusetts, to see through the press an edition of part of the *Heb.* Here he studied Hebrew under Professor Stuart, but in 1826 went to Germany, where he studied under Gesenius and Neander, and married as his second wife Therese A. L. von Jakob, daughter of a professor at Halle. In 1830 he became extra-ordinary professor of Sacred Literature at Andover, in 1837 professor of Biblical Literature in the Union Theological Seminary, New York. He now made an extensive survey of Palestine, collecting materials for *Biblical Researches in Palestine and Adjacent Countries* (3 vols. 1841). A second visit in 1852 yielded fruit for its second edition (1856). Robinson died in New York, 27th January 1863.

His other works are a translation of Buttmann's *Greek Grammar* (1832); *Greek and English Lexicon of the New Testament* (1836; 1850); *Harmony of the Gospels*, in Greek (1845), and in English (1846). He was also editor of the *Biblical Repository*, *Bibliotheca Sacra*, *Cabinet's Bible Dictionary*, and a translation of Gesenius' *Hebrew Lexicon*.

His wife, THERESE ALBERTINE LOUISE VON JAKOB, well known to the world of letters as 'Tulvi,' a name composed of her initials, was born at Halle, January 26, 1797. At ten she went to Kiarkoff in Russia, where her father had become professor, but in 1810 they removed to St Petersburg. In 1816 they returned to Halle, and here she studied Latin, and wrote her volume of tales, *Psyche* (1825). As 'Ernest Berthold' she published translations of Scott's *Black Dwarf* and *Old Mortality*, and also two volumes of Serbian popular songs, *Volllieder der Serben* (1825-26). In 1828 she married Robinson, and in 1830 accompanied him to America. After his death she lived mostly at Hamburg, where she died 13th April 1869.

Robinson, EDWIN ARLINGTON, poet, was born 22d December 1869, near Gardiner, Maine, and studied at Harvard. From 1896 on he published verses. *Captain Craig* (1902) gained him President Roosevelt's admiration and a place in the Custom House at New York (1905-10). *The Town*

down the River (1910) increased his reputation, and *The Man Against the Sky* (1916) placed him in the front rank of American poets. It was followed by *Martin* (1917), *Lancelot* (1920), *The Three Taverns* (1920), *The Man who died Twice* (1924). His poems were collected in 1922 with an introduction by John Drinkwater. Mr Robinson's poetry is intellectual, pale in its tones, technically of very high accomplishment, with an epigrammatic justness that could not be bettered.

Robinson, HENRY CRABB, born of middle-class parentage at Bury St Edmunds on 13th May 1775, was educated there and at Devizes, and then was articled to a Colchester attorney (1790-95). He studied five years at Jena, Weimar, &c. (1800-5), making friends or acquaintances of nearly all the great German spirits of the day, and during 1807-9 was engaged on the *Times*—in Spain, the first war-correspondent. In 1813, at the age of thirty-eight, he was called to the bar, from which, having risen to be leader of the Norfolk circuit, he retired in 1828 with £500 a year. 'In looking back on his life, Mr Robinson used to say that two of the wisest acts he had done were going to the bar and quitting the bar.' Thenceforth he lived chiefly in London, with frequent tours both at home and abroad till 1863, giving and receiving much hospitality, until at the ripe age of ninety-one he died unmarried on 5th February 1867. A dissenter and a Liberal, he was one of the founders of the London University (1828), an early member of the Athenæum Club (1824). Withal he was a splendid talker, who 'talked about everything but his own good deeds,' a buoyant companion, an earnest thinker, a prodigious reader, content not to publish but to keep a diary. 'I early found,' he says, 'that I had not the literary ability to give me such a place among English authors as I should have desired; but I thought that I had an opportunity of gaining a knowledge of many of the most distinguished men of the age, and that I might do some good by keeping a record of my interviews with them. True [which was not quite true], I want in an eminent degree the Boswell faculty; still, the names recorded in his great work are not so important as Goethe, Schiller, Herder, Wieland, the Duchesses Amelia [Anulda] and Louisa of Weimar, Tieck, as Madame de Staël, La Fayette, Abbé Grégoire, Benjamin Constant, as Wordsworth, Southey, Coleridge, Lamb, Rogers, Hazlitt, Mrs Barbauld, Clarkson, &c., &c., &c. for I could add a great number of minor stars. And yet what has come of all this? Nothing. What will come of it? Perhaps nothing.' Yes, something has come of it—the three delightful volumes, edited in 1869 by Dr Sadler, of his *Diary, Reminiscences and Correspondence*, which will last as long as literature itself, and Professor Edith Morley's selections, *Blake, Coleridge, Wordsworth, Lamb, &c.* (1922).

Robinson, JOHN, pastor of the Pilgrim Fathers, was born, probably in Lincolnshire, about 1575, was a Fellow of Corpus Christi, Cambridge, and ministered to a church near Norwich, until he was suspended for his Puritan tendencies. In 1604 he resigned his fellowship and all connection with the Church of England, and gathered a congregation of dissenters at Gainsborough. He was afterwards a minister at Scrooby, but in 1608 he and his flock escaped to Amsterdam; in 1609 he passed to Leyden, and there in 1611 he established a church, and in 1613 met Episcopius, Arminius's successor, in debate. In 1620, after a memorable sermon, he saw the younger members of his congregation set sail in the *Speedwell* (which vessel they afterwards changed for the *Mayflower*). He himself intended to, and his son in 1631 did, follow them to Massachusetts. He died at Ley-

den in March 1625. His works, with a memoir by R. Ashton, were collected in 3 vols. (Lond. and Boston) in 1851. In 1891 a large bronze tablet to his memory was placed by the American Congregational churches on the outer wall of St Peter's, Leyden, in one of whose vaults he is buried. See Lives by Davis (Boston, 1903), and Powicke (1920).

Robinson, MARY, 'Perdita' (1758-1800), born at Bristol, played 'Perdita' and other Shakespearian parts at Drury Lane 1776-80, and became mistress in 1779 to the future George IV. (q.v.), who gave her a bond (never paid) for £20,000. Long a conspicuous personality, she wrote poems, plays, and novels; in 1783 got a pension of £500, but died poor and palsied. See her Memoirs, edited by her daughter (1801).

Robinson, MARY. See DARMESTETER.

Robison, JOHN, was born at Boghall in Stirlingshire in 1739, and educated at Glasgow grammar-school and university. He devoted himself early to physical science, became acquainted with James Watt and Dr Black, and succeeded to the latter's chair on his transference to Edinburgh in 1766. Four years later he went to Russia as secretary to Admiral Knowles, who had been appointed president of the Russian Board of Admiralty. In 1774 he accepted the chair of Natural Philosophy at Edinburgh, but he made an indifferent lecturer, and disliked experiments. He died January 28, 1805. His *Elements of Mechanical Philosophy* was edited by Sir D. Brewster (4 vols. 1822). His foolish *Proofs of a Conspiracy against all the Religions and Governments of Europe, carried on in the Secret Meetings of Freemasons, Illuminati, and Reading Societies* (1797) is a lasting monument of fatuous credulity.

Rob Roy (Gaelic, 'Red Robert'), the Scottish Robin Hood, was born in the year 1671, the second son of Lieut.-colonel Donald Macgregor of Glengyle. Till 1661 the 'wicked clan Gregor' had for more than a century been constantly pined with fire and sword; the very name was proscribed. But from that year until the Revolution the severe laws against them were somewhat relaxed; and Rob Roy, who married a kinswoman, Mary Macgregor, lived quietly enough as a grazier on the Braes of Balquhither. From youth, however, he was a master of the clay more, the uncommon length of his arms giving him much advantage, for without stooping he could tie the garters of his Highland hose, 2 inches below the knee. Then his herds were so often plundered by 'broken men' from the north that he had to maintain a band of armed followers to protect both himself and such of his neighbours as paid him blackmail. And so with those followers, espousing in 1691 the Jacobite cause, he did a little plundering for himself, and, two or three years later having purchased from his nephew the lands of Craigroyston and Inversnaid, laid claim thenceforth to be chief of the clan. In consequence of losses incurred about 1712 in unsuccessful speculations in cattle, for which he had borrowed money from the Duke of Montrose, his lands were seized, his houses plundered, and his wife shamefully used, turned adrift with her children in midwinter. Madened by these misfortunes, Rob Roy gathered his clansmen and made open war on the duke, sweeping away the whole cattle of a district, and kidnapping his factor with rents to the value of more than £3000 Scots. This was in 1716, the year after the Jacobite rebellion, in which at Sheriffmuir Rob Roy had 'stood watch' for the booty, and had been sent by the Earl of Mar to raise some of the clan Gregor at Aberdeen, where he lodged with a kinsman, Professor Gregory. Marvellous stories are current round Loch Katrine and Loch Lomond (where a cave near Inversnaid still bears his name)

of his hairbreadth escapes from capture, of his evasions when captured, and of his generosity to the poor, whose wants he supplied at the expense of the rich. They in return gave him timely warning of the designs of his two arch-foes, the Dukes of Montrose and Athole, and of the red-coats they called to their aid from Dumbarton and Stirling; besides, Rob Roy enjoyed the protection of the Duke of Argyll, having assumed the name Campbell, his mother's. Late in life he is said to have turned Catholic, but in the list of subscribers to the Episcopalian church history of Bishop Keith occurs the name 'Robert Macgregor alias Rob Roy.' The history came out in 1734, and on the 28th December of that same year Rob Roy died in his own house at Balquhither. He left five sons, two of whom died in 1754—James, an outlaw, in Paris; and Robin, the youngest, on the gallows at Edinburgh for abduction.

See the introduction and notes to Scott's *Rob Roy* (1817); Dorothy Wordsworth's *Tour in Scotland in 1803*, with her brother's poem; and the *Lives of Rob Roy* by K. Macleay (1818; new ed. 1881) and A. H. Millar (1883).

Robsart, AMY. See LEICESTER, EARL OF.

Robson, FREDERICK, whose real name was F. R. BROWNELL, low comedian, was born at Margate in 1821. He was apprenticed to a London copper-plate engraver; but became smitten with stage fever and took to the actor's life (1844). From 1853 he was inseparably associated with the Olympic Theatre of London, where he attracted large audiences for years by his representations in comedy, farce, and burlesque. An actor of original genius, Robson excelled in parts that were grotesque, eccentric, quaintly humorous or diabolical; he was particularly effective in sudden transitions from comicality to pathos, and the reverse, and in the delineation of violent and tumultuous passion. He gave a vivid portrait of the street outcast as Jim Bagges in the *Wandering Minstrel*, in which he sang the once celebrated 'Villikins and his Dinah.' He burlesqued Macbeth and Shylock, mimiting in his playing the hideous and the terrible. One of his principal characters was De-monetts, a spy of Fouché's, in the play *Plot and Passion*; others were the dwarf in Planche's *Yellow Dwarf*, and Uncle Zachary in *Peter and Paul*. He died 12th August 1864.

See Dutton Cook in *Gentleman's Magazine* (1882), and the sketch by G. A. Sala (1864).

Robson, MOUNT, a magnificent peak of the Rocky Mountains in British Columbia, next the Fraser River and the Canadian National Railway, over 13,000 feet high, with great glaciers.

Roburite, a flameless explosive, composed of chlorinated dinitro-benzene mixed with enough ammonium nitrate to oxidise it completely.

Roe, or RUKI, a fabulous bird of immense size, able to carry off an elephant in its talons. The idea is familiar in the East, and every reader will remember it in the *Arabian Nights' Entertainments*. Colonel Yule pointed out that the huge fronds of the Raphia (q.v.) palms were brought from Madagascar as roc's feathers. Mythical birds of similar size and strength were the Arabian 'anku and the Persian *simurgh*. The *anru* or *sinamru* was an older Persian supernatural bird; the Indian *garuda*, which bears Vishnu, is the king of birds.

Rocamboles (*Allium Scorodoprasum*), a plant of the same genus with garlic, onion, leek, &c., and nearly allied to garlic, which it resembles in its habit, although larger in all its parts. The root forms rounder cloves than those of garlic, and of much milder flavour; the umbels are also bulbiferous. Rocamboles has long been cultivated in kitchen-gardens. It is a native of sandy

soils in Denmark and other countries near the Baltic.

Roccella. See ARCHIL.

Rocha, a south-eastern department of Uruguay, on the Atlantic; hilly in the south, in the north a swamp. Area, 4280 sq. m.; pop. 54,000.

Rochambeau, JEAN BAPTISTE DONATIEU DE VIMEURE, COMTE DE, was born at Vendôme, 1st July 1725, entered the army in 1742, was at the siege of Maestricht, and distinguished himself at Minorea in 1756. In 1780 he was sent out in command of an army of 6000 men to support the Americans, and in 1781 he rendered effective help at Yorktown. He became marshal in 1791, and in 1804 Napoleon made him a grand officer of the Legion of Honour. He died 10th May 1807. See his *Mémoires* (2 vols. 1809; Eng. trans. 1838).

Rochdale, a thriving manufacturing town of Lancashire, a municipal, parliamentary, and county borough, on the Roche, 11 miles N. by E. of Manchester and 202 NNW. of London. St Chad's parish church, on an eminence approached by a flight of 122 steps, dates from the 12th century, but is mainly Perpendicular in style. It is a handsome edifice, on which £10,000 was expended in 1844-85. The town-hall, erected in 1866-71, is a very fine Gothic building. The town besides has an infirmary (1883), a library (1884), a post-office (1875), an art gallery and museum (1903), public baths (1898), a statue of John Bright, technical and other schools, parks and playgrounds. Many improvements have been effected, in particular the covering over of the river. The town derives its importance wholly from its extensive and varied manufactures. To the growing of wool was added a trade in woollen goods in the days of Elizabeth, when cotton goods also were sold, and coal-pits worked. Under the Sturats the woollen manufacture was in full activity; but it was not till 1795 that the first cotton-mill was built, in which in 1802 the father of John Bright began his career as a weaver. Cotton spinning and weaving is now the staple industry, but there are also flannel mills, foundries, engineering works, &c. Rochdale is the birthplace of Co-operation (q.v.). Since 1832 Rochdale has returned one member to parliament, and in 1836 it was incorporated as a municipal borough. The county borough is coterminous with the parliamentary borough. The manor of Rochdale (*Rocedam* in Domesday) was originally held by the Luelys of Pontefract, and through their descendants, the Dukes of Lancaster, passed to the crown. In 1628 it was sold to Sir John Byron, whose descendant, the poet Lord Byron (of Rochdale), sold it in 1823. Pop. (1851) 29,195; (1911) as extended in 1900, 91,428; (1921) 92,700.

Roche, SIR BOYLE (1743-1807), an Irish bull-making M.P., created a baronet in 1782.

Rochefort, HENRI, whose full style was Victor Henri, Marquis de Rochefort-Lucay, a storm-petrel of French politics, was born in Paris, 29th July 1832. He studied medicine, and became a clerk in the hôtel-de-ville, but was dismissed for neglecting his duties, and cast himself entirely upon journalism, contributing to the *Charivari*, the *Figaro*, and other papers, until in 1868 he started his own notorious weekly, *La Lanterne*, which was quickly suppressed by the government. To avoid fine and imprisonment Rochefort fled to Brussels, but returned in 1869 on his election to the Chamber of Deputies for Paris. He now started the *Marscitaine*, in which he renewed his bitter attacks on the imperial regime. One consequence of the cowardly murder of its contributor, Victor Noir, by Prince Pierre Bonaparte, was the suppression of the paper and the imprisonment of its editor. The fall of

the empire gave him his release. In 1871 he was elected by Paris to the National Assembly, soon sided with the Communards, but, fleeing from Paris before the fall of the Commune, was by the Versailles government sentenced to imprisonment for life, and later deported to New Caledonia, whence he escaped in 1874. From London and Geneva he returned after the amnesty of 1880, in his *L'Intransigeant* showed himself as impracticable as ever, sat in the National Assembly (1885-86), took up Bonlangism, went into exile with Boulanger, and made the most of the Panamá scandals. Returning to France in 1895, he published *Les Aventures de ma Vie* (trans. 1896), and gadded on the anti-Dreyfus party. He died 30th June 1913.

Rochefort, a small town of Belgium in Namur province at the foot of the Ardennes, with remarkable grottoes.

Rochefort-sur-mer, a French seaport, naval arsenal, and fortress, in Charente-Inférieure, stands on the right bank of the Charente, 9 miles from its mouth, and 18 miles SSE. of La Rochelle. It was founded in 1665 as a naval station by Colbert, Louis XIV.'s minister, and fortified by Vanban, being covered now on the sea side by strong forts; and it is a modern, clean, well-built place, with which few French towns can compare for the number and importance of its public works. The most celebrated of these is the naval hospital (1783-88), with an artesian well 2758 feet deep. There are both a naval harbour and, higher up the river, a commercial harbour with three basins; and Rochefort besides possesses establishments for the manufacture and preservation of naval stores and marine apparatus of every kind. From 1777 till 1852 it was the seat of a great convict prison. Napoleon meant to take ship for America at Rochefort, but instead had to surrender to Captain Maitland of the *Bellerophon*, 15th July 1815. Pop. (1872) 26,619; (1911) 35,019; (1921) 29,473.

Rochefoucauld. See LA ROCHEFOUCAULD.

Rochefacquelein. See LAROCHEJACQUELEIN.

Rochelle, LA, an important seaport and fortress of western France, capital of the département of Charente-Inférieure, on an inlet of the Bay of Biscay, formed by the islands Ré and Oléron, 91 miles WSW. of Poitiers and 297 SW. of Paris. Its harbour, which consists of an outer harbour and inner basins, is still sheltered by the remains of Richelieu's famous dyke. Large ships use the harbour at La Pallice, 3 miles WSW., inaugurated in 1891. Many of the streets and squares are regular and well built, and present a handsome appearance from the number of houses which are adorned with porticoes and balconies. The most noteworthy public buildings are the hôtel-de-ville (1486-1607), the palais-de-justice (1614), and the heavy Grecian cathedral (1742-1862). Besides the fine promenade of the Place du Château, there are, outside the city, two extensive public gardens, known as the Promenade du Mail and the Champs de Mars. La Rochelle is transforming itself into a great fishing port. There is some shipbuilding, especially for the Newfoundland fishery; tinning of sardines and tunny fish; manufacture of textiles, bricquettes, porcelain, and glass ware, with refineries of sugar and petroleum, and brandy distilleries. Pop. (1872) 19,070; (1911) 36,371; (1921) 39,770. La Rochelle was known till the 12th century under its Latin name of *Rupella*, 'Little Rock,' of which its present name is a translation. It originated in a colony of serfs of Lower Poitou, who, fleeing from the persecution of their lord, settled on the rocky promontory between the ocean and the neighbouring marshes. On the marriage of Eleanor of Aquitaine

with Henry II. of England, La Rochelle, as part of her dowry, came into the possession of the English kings, by whom it was retained till 1224, when it was taken by Louis VIII.; and, although it was ceded to England at the treaty of Breigny in 1360, in the subsequent wars it was retaken by France, under whose sway it has remained since 1372. A stronghold of the Huguenots (q.v.), it was unsuccessfully besieged in 1573, and in 1627-28 it for fourteen months again offered a heroic though unavailing resistance, under its mayor Guiton, to Cardinal Richelieu. Buckingham's expedition to relieve it failed, and at last the defenders, reduced from 27,000 to 5000, had to surrender to the troops of Louis XIII. With the exception of three towers (1384-1476) its old fortifications were destroyed, and new lines of defences subsequently erected by the great Vauban. Réaumur, Bonpland, Billaud-Vareune, Fromentin, Bongeruean, and Admiral Duperré (1775-1846) were natives.

Rochelle Salt is the popular name of the tartrate of soda and potash ($\text{KNaC}_4\text{H}_4\text{O}_6 + 4\text{H}_2\text{O}$), this salt having been discovered in 1672 by a Rochelle apothecary named Seignette. It occurs, when pure, in colourless transparent prisms, generally eight-sided; and in taste it resembles common salt. It is prepared by neutralising cream of tartar (bitartrate of potash) with carbonate of soda. After a neutral solution has been obtained, it is boiled and filtered, and the resulting fluid is concentrated till a pellicle forms on the surface, when it is set aside to crystallise. This salt is a mild and efficient laxative, and is less disagreeable to the taste than most of the saline purgatives. From half an ounce to an ounce, dissolved in eight or ten parts of water, forms an average dose. A drachm of Rochelle Salt added to one of the ingredients of an effervescent draught (bicarbonate of soda or tartaric acid, for example) forms one of the varieties of what are called Seidlitz powders.

Roches moutonnées, smooth, rounded, hummocky bosses and undulating surfaces of rock, of common occurrence in regions which have been overflowed by glacier-ice. Those which have not been much acted upon by the weather generally show the scratches and groovings which are the characteristic markings of glacial action. Sometimes roches moutonnées are smoothed and polished all over, and have the appearance of whales' or dolphins' backs. At other times they are smoothed only on one side—that side, namely, which faces the direction from which the glaciating agent flowed; the other side, protected from abrasion, being left in its original rough, unpolished condition. The name is said to have been applied by De Saussure from the resemblance of the rocks to the wigs of his day, known as moutonnées, rather than to a flock of sheep lying down.

Rochester, a city of Kent, 29 miles ESE. of London, lies on the banks of the tidal Medway, here crossed by a steel girder bridge (1914), and is continuous with Chatham. The castle or keep, which crowns a steep eminence near the bridge, was the work of Archbishop William de Corbeil (1126); but the wall overlooking the river contains Norman masonry of earlier date, built upon Roman foundations. The castle is 104 feet high and 70 feet square, with walls 12 feet thick, and is a very fine specimen of Norman architecture; it was taken by John (1215, the south-east corner being rebuilt shortly afterwards), vainly attacked by De Montfort (1264), and taken again by Tyler (1381). Both castle and grounds were purchased in 1883 by the corporation from the Earl of Jersey. The episcopal see was founded in 604 by St Augustine, and the foundations of the cathedral then built were discovered in 1891. Bishop Gundulf (1077-1107) built

a new cathedral, of which part of the crypt remains. This cathedral was rebuilt by Ernulf and John of Canterbury (1115-37), whose nave remains; and the choir was again rebuilt and enlarged in the 13th century in part out of offerings of pilgrims at the shrine of St William of Perth, a Scottish baker, who, on a pilgrimage to the Holy Land, was murdered near Chatham by his companion and adopted son; the tower rebuilt in 1825 and in 1904, the choir and transepts restored by Scott (1871-77), and the west front by Pearson in 1891; and extensive work has been done in the chapter-room, choir aisles, and organ. The cathedral measures 306 feet in length, and has double transepts; and special features of interest are the Norman west doorway and nave, the Early English choir, of singular plan and early character, the spacious crypt, and a fine decorated doorway leading to the modern library. The ruins of an early Norman tower (once used as a bell tower) built by Gundulf, the architect of the Tower of London, stand on the north side of the choir. Of Rochester's bishops since 604 may be mentioned Paulinus (previously first bishop of York), Gundulf, Walter de Meiton, Fisher, Ridley, Atterbury, and Housley. St Bartholomew's Hospital, founded by Gundulf in 1078 for lepers, was refounded in 1863; the Norman chapel remains. Watts' Charity House, founded in 1579 to lodge 'six poor travellers, not being rogues or proctors,' has been immortalised by Dickens, whose home, Gadshill (q.v.), is 3 miles distant. The cathedral grammar school dates from Henry VIII., Williamson's mathematical school from 1701; other buildings are Satis House, Restoration House, the guild-hall (1687), and the corn exchange (1871). There is some shipping, an oyster fishery, and manufactures of oil, oil-cake, cement, and agricultural implements; Chatham government works employ many of the inhabitants. Rochester—the Roman station *Durobriva* and Old English *Hrafe caestre*—was made a municipal borough by Henry II. It lost one of its two members in 1885; and the parliamentary borough of 1918 includes Chatham and Gillingham. James II. embarked here in his flight (1688). Pop. (1851) 16,508; (1871) 18,352; (1891) 26,170; (1921) 31,261.

Rochester, (1) capital of Monroe county, New York, is on both sides of the Genesee River, 7 miles above its entrance into Lake Ontario, and on the Genesee Valley canal, by rail 67 miles ENE. of Buffalo and 360 NW. of New York. The river has here three perpendicular falls of 96, 26, and 83 feet, and affords immense water-power. The city is well built, and laid out with almost unbroken regularity. Among the principal buildings are the city hall, of blue limestone, and the court-house; a state industrial school (formerly a 'house of refuge'); numerous churches, including a Roman Catholic cathedral; the Free Academy, and the university (founded 1850, and under Baptist control), and a Baptist theological seminary (whose library includes that of Neander). There are also many public and private schools, libraries, asylums, hospitals, &c. But the most noteworthy structure in the city is the handsome stone aqueduct of seven arches (850 feet long) by which the Erie Canal crossed the river. When the canal became part of the New York State Barge Canal, which now runs through the south of Rochester, the deserted loop in the centre of the city (including the aqueduct) was acquired by the municipality (1921) for conversion into a system of rapid road and rail transport. The industries include flour-milling, which has always been extensively carried on here, the manufacture of clothing, boots and shoes, furniture, carriages, iron bridges, cutlery, photographic, optical, and other apparatus, and fruit-canning. In the neighbourhood there are great nurseries, and in the

city large seed-packing establishments. Rochester is a port of entry, and has a considerable trade both by lake and rail. It was settled in 1810, incorporated in 1834. Pop. (1840) 20,191; (1860) 48,204; (1880) 89,366; (1900) 162,608; (1910) 218,149; (1920) 295,750.—(2) Capital of a county in Minnesota, on the Zumbro River, 347 miles by rail N.W. of Chicago, with flour-mills and a state asylum. Pop. 14,000.—(3) A city of New Hampshire, 11 miles N.W. of Portsmouth, with manufactures of woollen and paper goods, shoes, &c. Pop. 10,000.

Rochester. JOHN WILMOT, EARL OF, the wittiest reprobate at the court of Charles II., was born at Ditchley in Oxfordshire, 10th April 1647, and was educated at Burford school and Wadham College, Oxford. He next travelled in France and Italy, and on his return repaired to court, where his handsome person and lively wit quickly made him a prominent figure. In 1665 he showed conspicuous courage serving under Sandwich against the Dutch, as well as the summer after under Sir Edward Spragge—facts which agree but ill with the stories that he would sink away in street quarrels and evade duels which he had himself provoked. With a friend, Mr Windham, he had entered into a formal engagement that, 'if either of them died, he should appear and give the other notice of the future state, if there was any.' Windham was killed in an attack upon Bergen, but did not afterwards disturb the rest of his friend, who now plunged into a life of the grossest debauchery, was for five years together continually drunk, and diverted himself constantly with extravagant frolics and buffoonery, such as the pursuit of low amours in mean disguises, and the acting of assumed characters, as a mountebank, a quack doctor, and the like. In the scarce intervals of intemperance he wrote excellent letters to his wife and son, and devoted himself to literature, writing personal satires, ecclesiastical and amatory songs, and too often obscene and licentious verses. Many of these, however, were doubtless fathered on him after his day. In these wild excesses he blazed out his youth and his health, till at the age of one and thirty he had exhausted the fund of life. On his death-bed he was convinced of the necessity of repentance by the arguments of Bishop Burnet, who writes: 'I do verily believe he was so entirely changed, that if he had recovered he would have made good all his resolutions.' He died 26th July 1680. His last conversations are touchingly described by Burnet in *Some passages of the Life and Death of John, Earl of Rochester* (1680; in vol. iv. of Wordsworth's *Ecclesiastical Biography*), a book, says Dr Johnson, 'which the critic ought to read for its elegance, the philosopher for its arguments, and the saint for its piety. It were an injury to the reader to offer him an abridgement.'

Rochester's verses show more wit than poetry, but he possessed in rich measure the gift of satire. An excellent example of this is his memorable epitaph on Charles II.:

Here lies our sovereign lord the king,
Whose word no man relies on;
He never said a foolish thing,
Nor ever did a wise one.

Equally well known is the description—'a merry monarch, scandalous and poor,' the line rhyming with which it is characteristically impossible to quote. Horace Walpole's judgment of his work is thus expressed in *Royal and Noble Authors*: 'Lord Rochester's poems have much more obscenity than wit, more wit than poetry, more poetry than politeness.' Before his death he expressed a wish that his indecent verses should be suppressed. Among his most famous poems are, 'When wearied with a world of woe,' Verses to Lord Mulgrave,

a Satire against Man (adapted from Boileau) and Verses upon Nothing. 'Why dost thou shade thy lovely face,' universally credited to him, was shown by Mr Tulin to come from Quarles's *Emblems*. Swinburne said that Dryden, 'greatest and best representative of the age at its best and worst, is not for a moment to compare as a song-writer to Rochester.' See *Rochester and other Literary Rakes*, by 'the author of *Sir Kenelm Digby*' (1902).—For Viscount Rochester, see KER, and OVERBURY.

Roche-sur-Yon, I.A. capital of the French department of Vendée, on the Yon, 50 miles SSE. of Nantes. In 1815-48 it was called *Boubaon-Vendee*, in 1848 *70 Napoléon-Vendee*. Pop. 14,000.

Rochet (Low Lat. *rochetus*; Old High Ger. *roech*, 'coat'; Ger. *rock*), a fine linen or lawn vestment proper to bishops and abbots, and worn also by canons of certain privileged chapters, and some other dignitaries. It is of the form of a surplice, but with sleeves fastened at the wrist; these formerly fitted more tightly to the arm than do the 'balloon sleeves' still commonly worn by Anglican bishops. In the Latin Church its use is very ancient. Formerly it appears to have been worn by clerics serving mass and by priests baptising, because it left their arms free (Lyndwood, quoted by Du Cange); but those priests who are privileged to wear the rochet are now commanded to regard it as a choir vestment, and are strictly forbidden to use it in the administration of the sacraments. In the First Prayer-book of Edward VI. the rochet was ordered to be worn by bishops at all public ministrations, and beside—i.e. over it—a surplice or alb. It is prescribed in the present Book of Common Prayer as part of the episcopal habit. The old 18th-century Anglican fashion of fastening the sleeves of the rochet to the chimere—leaving the rochet itself sleeveless—is almost gone out.

Rock. Though popularly restricted to masses of indurated matter, this term is extended by geologists to all substances which make up the crust of the earth, whether they be loose and friable like soil and sand, or compact and indurated like limestone and granite. The rocks of the earth's crust are described under their several headings; see also PETROGRAPHY, GEOLOGY, DENUDATION, BUILDING STONE, BLASTING, BORING.

Rockall, on a deeply covered sandbank in the Atlantic 50 miles long and 25 broad, 160 miles W. of St Kilda, and 260 from the north of Ireland. It is an isolated conical granitic rock on stratified masses, rising 70 feet above the sea, and about 100 yards in circumference.

Rock-butter, an impure alum efflorescence found oozing from some alum slates.

Rock-crystal. See QUARTZ.

Rockefeller, JOHN DAVIDSON, American millionaire, was born at Richford, N.Y., in 1839. He made his fortune in oil, reorganising the whole industry, securing monopolies, absorbing rival enterprises, and in 1870 founding the Standard Oil Company. He retired from business in 1911. He is credited with having altogether given more than 500 million dollars for charitable or educational purposes, much of this being devoted to medical research and other university work. In 1909 he published *Random Reminiscences of Men and Events*.

Rocket is a cylindrical case of paper or metal partially filled, under heavy pressure, with an inflammable composition similar to gunpowder, but with a smaller proportion of saltpetre, so that a large conical hollow is left inside. The base is open or has vents in it, and the head closed. On being ignited this composition, burning over the whole surface of the hollow portion, at once causes

a great rush of gas out of the base, thus driving the rocket forward with great and increasing velocity. Rockets are used for Signalling (q.v.) and to carry a light line for life-saving purposes (see LIFE-SAVING APPARATUS). Early in the 19th century they began also to be used in war. Sir William Congreve in 1808 introduced iron war-rockets up to 24 lb. in weight, with thick iron heads adapted to act like a shell. They were fired from a tube, and steadied in their flight by means of long sticks. In the more modern Hale rocket a rotary motion is given by causing the gas to pass out of vents in the base bored between three projecting shields, shaped somewhat like the blades of a screw-propeller, against which it presses. This keeps the rocket travelling point first, and the cumbersome stick being therefore no longer needed, the rocket is fired from a low brough with tripod stand, or even from the ground, by raising the head to the height necessary to give the required range, which may be as much as 4000 yards. Though extremely portable, as compared with other missile weapons of similar power, rockets are so uncertain in their flight that they are not much used, except for incendiary purposes and against savages, who greatly dread them. Against cavalry they would be very useful if they could be depended on. Congreve's rockets were very effective at Leipzig in 1813, and were used in the Peninsular and second American wars, and at Waterloo. At one time there were two rocket troops of the Royal Horse Artillery. See PYROTECHNY.

Rocket, a name given to a number of plants of the family Cruciferae, belonging to the genera *Brassica*, *Sisymbrium*, *Erysimum*, *Barbarea*, *Hesperis*, &c. Garden Rocket (*Brassica Eruca*, or *Eruca sativa*) is an annual plant of the Mediterranean region, with stem 2 feet high, upright and branching; the leaves smooth, succulent, cut and toothed. When in flower it has a strong, peculiar, and disagreeable smell; but when it is very young this smell is almost imperceptible, and the leaves are used as a salad, for which it is frequently sown on the continent of Europe, and was formerly cultivated also in Britain. The name Garden Rocket is given also to *Hesperis matronalis*, also called Dame's Violet (q.v.). The Yellow Rocket of our flower-borders is a double-flowered variety of *Barbarea vulgaris* (see CRESS). The Wild Rocket (*Sisymbrium officinale*) is common in Britain, and is sometimes sown and used as a spring potherb.

Rock-fish. See WRASSE.

Rockford, capital of Winnebago county, Illinois, is on both sides of the Rock River, 86 miles by rail WNW. of Chicago. It is a well-built town, with shady streets, contains many furniture factories, and also makes hosiery, agricultural implements, machinery, and a great variety of other goods. Pop. (1880) 13,129; (1890) 23,584; (1910) 45,401; (1920) 65,651.

Rockhampton, a town of Queensland, on the south bank of the Fitzroy, 35 miles from its mouth, and 420 NW. of Brisbane. It has wide streets, lined with trees, and many substantial buildings. It owes its beginning (1858) to an unsuccessful gold-rush, after which, being at the head of navigation on the Fitzroy, it became the natural port of the great pastoral district behind it. Many years later (in 1886) a hill saturated with gold was discovered at Mount Morgan, 20 miles away. Extensive coal-beds are found not far off; and much copper is produced in the neighbourhood. Rockhampton is connected by rail with Brisbane and south, with Longreach in central Queensland, and with Mackay and the northern coast districts. As a port it is the third in Queensland, in spite of its winding tidal river. A bridge across the

Fitzroy, with five spans of 232 feet each, connects Rockhampton with its suburb North Rockhampton. Pop. 24,000.

Rockingham, CHARLES WATSON WENTWORTH, MARQUIS OF, a statesman of importance beyond his abilities, was born in 1730, the only son of Thomas Watson Wentworth, sixth Lord Rockingham, and first marquis (1746); and he succeeded his father as second marquis in 1750. In 1751 he was nominated lord-lieutenant of the North and West Ridings of Yorkshire; but as opposed to the policy of George III. and Bute, he was dismissed in 1762. He found himself leader of the combination of Whig opposition, after the Duke of Devonshire's death in 1764, and in July 1765 was called on to form his first ministry. He repealed the Stamp Act, and would have done more for progress but for the secret intrigues of the court, added to the defection of the Duke of Grafton and his own want of influence in parliament. Rockingham resigned in August 1766, and remained out of office sixteen years in opposition to Lord North and the ruinous policy that lost America. He again became prime minister in March 1782, with Fox and Shelburne as his secretaries, but died 1st July of the same year. See the *Memoirs* by Lord Albemarle (2 vols. 1852).

Rocking-stones, or LOGANS, are large masses of rock so finely poised as to move backwards and forwards with the slightest impulse. They occur in nearly every country. Some of them appear to be natural, others artificial; the latter seem to have been formed by cutting away a mass of rock round the centre-point of its base. The former are chiefly granitic rocks, in which felspar is abundantly present; for, this mineral being readily decomposed, the rock becomes disintegrated to grit, sand, and dust, which are carried away by rains and wind, so that what was formerly a solid rock soon assumes the appearance of a group of irregularly-shaped pillars, separated into portions by horizontal and vertical fissures. As decay proceeds, the edges of the blocks forming the pillar are first attacked and disappear, and the pillar now becomes a pile of two or more spheroidal rocks, resting one upon the other. Should a mass of rock be so situated as to preserve its equilibrium in spite of the gradual diminution of its base or point of support, a rocking-stone or logan is the result. Although rocking-stones are most frequently of a granitic nature, they occur also among basalts and other crystalline igneous masses. For the principle regulating the stability of equilibrium of rocking-stones, see STABILITY. Various explanations have been given of the uses of these singular objects. They are supposed to have been used in very early times for purposes of divination, the number of vibrations determining the oracle; hence it came to be believed that sanctity was acquired by walking round them.

Some rocking-stones occur near to remains of ancient fortifications, which seems to bear out a statement in one of the poems of Ossian, that the bards walked round the stone singing, and made it move as an oracle of the fate of battle. In Greece rocking-stones occur as funeral monuments, and are generally found on conspicuous places near the sea. Rocking-stones are numerous in Yorkshire, Derbyshire, Cornwall, and Wales. The famous Logan Rock, near Land's End, in Cornwall, is computed to weigh over 70 tons. It was wantonly displaced in 1824 by Lieutenant Goldsmith, R.N., and his boat's crew of nine men. He had to replace it at a cost to himself of £2000; but whether it has since rocked as well as ever is a moot point. Near Warton Crag, Lancashire, are no less than seven of these stones; and in Scotland they occur in the

parishes of Kirkmichael, Dron, and Abernethy, Perthshire, and Kells, Kirkcudbrightshire. In Ireland they are found in many places; one situated at a place called Islandmagee, on Brown's Bay, County Antrim, is popularly believed to acquire a rocking tremulous motion at the approach of sinners and malefactors. At Andafjord (Faeroe Islands) a large block of basalt, measuring some 16 feet in length by 10 feet in breadth, and rising for about 10 feet out of the water, swings to and fro with the motion of the sea, which is about seven fathoms

Rocking-stone of Tandil.

deep. The rocking-stone of Tandil in the Argentine Republic, 250 miles S. of Buenos Aires, weighs over 700 tons, yet is so nicely poised that it rocks in the wind, and may be made to crack a walnut. See Frank Vincent's *Around and About South America* (1890), from which our illustration is copied.

Rock Island, capital of a county of that name in Illinois, on the Mississippi, opposite Davenport, Iowa (the two are connected by bridges), 181 miles by rail WSW. of Chicago. The island from which the town is named has a great arsenal and armory. The channel to the east of the island has been dammed so as to furnish immense water-power, and the city has saw mills, besides steel-works, soap-works, &c. Pop. 35,000.

Rockland, (1) capital of Knox county, Maine, on the west side of Penobscot Bay, 88 miles by rail ENE. of Portland. The city has granite quarries, many lime-kilns, and shipyards. Pop. 8000. —(2) Rockland, Massachusetts, 19 miles by rail SSE. of Boston, has large boot and shoe factories, and a pop. of 7500.

Rockling (*Omus*), a genus of fishes of the Cod family Gadidae, represented on the British coasts

Three-boarded Rockling or Sea Loach.

by several species distinguished among other things by the number (3-5) of barbels. The larger species reach a length of 17 inches; but none are of any value as food, their flesh acquiring an unpleasant

smell a few hours after being taken out of the water.

Rock-oil. See PETROLEUM.

Rock River rises in the south-eastern portion of Wisconsin, and flows south into Illinois, thence south-west, and empties itself into the Mississippi 3 miles below Rock Island. Its course of 375 miles, much broken by falls, is through a region noted for its beauty and fertility.

Rock-rose. See CISTUS.

Rock-salt. See SALT.

Rock-soap, a dark unctuous clay containing a small percentage of iron oxide and about 24 per cent. of water. It is a variety of bole, and has sometimes been classed as a mineral. It is earthy, easily broken, black or nearly so, very soft, and easily cut with a knife, is greasy to the touch, and adheres strongly to the tongue. It is valued by painters for crayons. It is found in Poland, Thuringia, and Bohemia, and occurs in basaltic-rocks in the Isle of Skye and Antrim, in the form of nodules of a greenish-gray or brown colour. It is only found massive.

Rock-temples. In many parts of Western India, as at Ellora, Elephanta, Karli, and Salsette Island, natural rocks have been cut into temples; as also into caves and fountains (see the articles mentioned). Out of India well-known instances of the same kind occur at Petra (q.v.) in the Arabian Desert, at Abu Simbel (q.v.) in Egypt, and in China and Siam. There are remarkable cave-temples in the United States, one in Missouri, between the Salt River and Otter Creek, and another near Manchester in Ohio.

Rocky Mountain Goat (*Oreamnus montanus*), a heavily built wild goat of the mountains from Alaska to Montana and Washington. It is marked by its shaggy white hair, its humped shoulders, its long head with small black horns. Very sure-footed, deliberate in its movements, with great presence of mind, well protected from the cold, able to thrive on scanty vegetation, it holds its own well and has few enemies. Its haunts are often inaccessible, and this helps its persistence. The flesh is musky and not very palatable. It is the only North American goat, and must be distinguished from the Prough-horn Antelope and from the Rocky Mountain Sheep, for which see SHEEP.

Rocky Mountains, a name formerly somewhat loosely applied to all the mountains of North America between the Great Plains and the Pacific Ocean, is now used to designate only the eastern ranges of the great Cordillerian system, but including the continuations beyond the Canadian frontier. This vast mountain-system acquires its greatest breadth within the limits of the United States, where between the parallels 38° and 42° N. lat. it attains a width of more than 1000 miles. Toward the north and the south the plateaus of this high-land gradually diminish in breadth, but they are enclosed on the east and on the west by high mountain-chains. Those forming the western boundary are the Sierra Nevada and the Cascade Ranges (q.v.), and the eastern chains stretching with interrupted continuity from the southern borders of the United States through the Dominion of Canada to the Arctic Ocean constitute the Rocky Mountains. Between these eastern and western boundaries the plateau region is greatly diversified by chains which, as a rule, trend in the same general direction as the border ranges.

The name 'Rocky Mountains' is peculiarly appropriate, as there probably exists nowhere else such an extensive region of naked rock almost entirely devoid of vegetation. The geological structure is complex, but the greater part of the

rocks exposed are Mesozoic intermingled with Tertiary and Quaternary deposits. As this system is consequently of much more recent origin than the Appalachians, it is naturally higher, and it presents also a sharper and more rugged outline. Its remarkably barren aspect is due also to other geological peculiarities and to climatic causes. In comparatively recent ages this whole region has been the scene of vast volcanic eruptions, and the lava overflows which have covered the stratified rocks in many places to a depth of thousands of feet have augmented the expanse of sterile surface. By resisting the erosion of the streams and of the atmosphere, these lava beds have also greatly aided in producing the precipitous and deeply furrowed watercourses by which this wonderful plateau region is traversed. The high mountain barrier at the western boundary of the highland rolls the winds which sweep across the Pacific of much of their moisture, and the great aridity of this region thus prevents the growth of vegetation, though there is heavy woodland in many sections. Elsewhere the surface is exposed to continued erosive action, the denudation being the more complete as the sand and smaller disintegrated fragments are swept away by the winds, and no opportunity is afforded for the accumulation of a soil. On account of these various causes the erosion of the surface is uneven, and the region displays a labyrinth of naked crags and peaks arising from plateaus crossed by towering cliffs or deep cañons, with here and there an isolated butte. The scenery of the wonderful *mesa* or plateau region which lies between the eastern and western ranges of the Rocky Mountains, and extends from southern Wyoming through western Colorado, eastern Utah, and south into New Mexico and Arizona, is unequalled by that of any other portion of the globe. The country is divided by faults, flexures, and deep cañons into numerous blocks or separate plateaus, and the wonderful carving of the rocks and the brilliant colouring of the exposed strata almost surpass belief.

A high plateau region in Wyoming, over which passes the Union Pacific Railroad, marks a separation of the Rocky Mountains into a northern and a southern group, each of which has its characteristic features. The continental divide which extends north and south with the ranges of the Rocky Mountains culminates in this plateau, where are found the extreme head-waters of the three great river-systems of the United States—the Mississippi, the Columbia, and the Colorado. The ranges of the southern group have a general north and south trend, and are higher than those of the northern group. As there are several elevated valleys known as 'Parks' enclosed between the parallel ranges, this group is sometimes known as the Park System. It extends southward from the Laramie Plains across central Colorado into New Mexico. Its greatest development is in Colorado, where there are nearly forty peaks each over 14,000 feet in height. The Medicine Bow Range and the Colorado or Front Range form the eastern edge of the Rocky Mountain System, and rise abruptly from the gentler slope of the Plains. In this range are the well-known landmarks, Long's Peak (14,271 feet) and Pike's Peak (14,134 feet), as well as Gray's Peak (14,341 feet), its highest point, which is too far west to be visible from the Plains. This range forms the eastern wall of North, Middle, and South Parks, and the Park Range constitutes their western boundary. To the west of the southern end of the Park Range lies the Sawatch Range, with the famous Mount of the Holy Cross (14,176 feet) and Mount Harvard (14,375 feet). Farther south are the San Juan Mountains, which constitute the western boundary of San Luis Park. To

the north and west of this range lies a high broken country merging into the *mesa* region of western Colorado. Uncompagne Peak (14,408 feet) is the culminating point of this section. The eastern border of San Luis Park is formed by the Sangre de Cristo Range, which is almost a continuation of the Sawatch. Its loftiest summit, Blanca Peak (14,463 feet), is the highest point of the 'Rockies.' The Elk Mountains, a series of short parallel ranges with sharp volcanic peaks, lie to the west of the Sawatch Range. In the Parks rise the head-waters of the North and the South Platte, the Arkansas, the Grand, and the Rio Grande. Beside these large parks there are among these ranges many smaller but beautiful valleys. West of the Park Range are the Uintah Mountains, composed of a broad fold of thick strata, of which the Upper Tertiary and Cretaceous layers have been eroded to the depth of more than 3 miles, exposing the underlying Carboniferous rocks. This range has an east and west trend, and connects the eastern and western ranges of the Rocky Mountain System. The most important of the western ranges are the Wahsatch Mountains, which form a part of the eastern rim of the Great Basin (q.v.), and which serve as the connecting link between the northern and southern groups of this system. The greatest development of the northern group is in Wyoming. The Wind River Mountains are the highest of the ranges, with Fremont's Peak (13,790 feet) as the culminating point. To the west are the Tetons, Mount Hayden (13,691 feet), and the Snake River Mountains. The mountains of the northern group are wilder and less accessible than those of the southern chains, but not so high. They also present scenery which is less varied: they are not so definitely marked by regular ranges, and there are but few prominent peaks except in the groups already mentioned and in the geyser region of the Yellowstone. In Idaho and Montana there are numerous enclosed mountain valleys, which are called 'Parks' or 'Prairies,' but they are not so high as the 'Parks' of Colorado. The Bitter Root Mountains form the divide between the head-waters of the Missouri and those of the Columbia, and also between the tributaries of Clarke's Fork and of the Snake River. The Lapwai and Coeur d'Alene ranges, which lie to the west and northwest, connect the Rocky Mountains with the Blue Mountains, and between these groups and the Cascade Range are the Great Plains of the Columbia River. Yellowstone Park (q.v.), in the north-western part of Wyoming, is famous for its hot springs, geysers, mud volcanoes, and its wonderful scenery. The disposition of the mountains toward the east is peculiar, as they occur in more or less detached and isolated groups, among which are the Crazy Mountains, Judith Mountains, and the Big Horn Mountains. Still farther east are the Black Hills, completely detached from the main system, and noted for their mineral wealth. Of the Canadian Rockies some forty peaks over 10,000 feet have been climbed, Mount Columbia (12,500) only in 1902. This region is notable for its numerous and often great glaciers. The highland gradually descends towards the north, reaching an elevation of about 800 feet in the vicinity of the Arctic Ocean, and the northern ranges form the divide between the head-waters of the Mackenzie and the Yukon Rivers.

Rococo, or **ROCAILLE**, a name given to the style of architecture and decoration which succeeded the first revival of Italian architecture. The ornament consists of panels with their mouldings broken or curved at the angles, and filled with leafage, shell-work, musical instruments, marks, &c.; but, above all, rococo is characterised by absence of restraint and lack of selection, true signs of de-

calence in art. It is ornamental design run mad, without principle or taste. The best rococo work dates from the earlier Louis Quinze period, but this

style prevailed in Germany and Belgium during the 18th century, and in France from Henry IV. to the Revolution. The illustration is from an altar in Antwerp. See BAROQUE.

Rocroi, a small town of the French department of Ardennes, 2 miles from the Belgian frontier, where Condé defeated the Spaniards in 1643.

Rod, called also a *pole*, or *perch*, a measure of length $5\frac{1}{2}$ yards, or $16\frac{1}{2}$ feet. The square rod, or *road*, employed in estimating masonry-work, contains $16\frac{1}{2}$ by $16\frac{1}{2}$ feet, or 272 $\frac{1}{2}$ square feet.

Rod, EDOUARD (1857-1910), born at Nyon in Switzerland, lectured on literature at Geneva in 1887-93, but from 1881 spent most of his life in Paris. Novelist and literary critic, he marked his departure from the school of Zola by *La Course à la Mort* (1885) and *Le Sens de la Vie* (1889), and in more than a dozen later novels dealt largely with moral problems on idealist lines. He wrote also on Goethe, Stendhal, and Rousseau.

Rodbertus, JOHANN KARL, designated the founder of scientific socialism, was born the son of a professor at Greifswald on 12th August 1805, and studied law at Göttingen and Berlin. For a few years he held law appointments under the Prussian government, but in 1836 settled down on his country estate at Jagetzow in Pomerania, and turned his attention chiefly to economic studies. In 1848 he was elected a member of the Prussian National Assembly, and for a fortnight filled the post of minister of Worship and Education; in the following year he carried the adoption of the Frankfurt constitution for the empire, but retired from public life when the Prussian electors were grouped in three separate classes. He died on 6th December 1875. Rodbertus believed that the socialistic ideal will work itself out gradually according to the natural laws of change and progress. Indeed he fixed upon five centuries as the time it will take to educate the people, the democracy, up to the socialistic ideal. When that ideal is realised the state will be the owner of all the land and capital of a country, and will superintend the distribution of the total products of human labour amongst those who do the labour, apportioning to each a share corresponding to his work. (His fundamental economic principle was of course that labour is the true and only source of wealth.) In the meantime he would not interfere with the working of the established laws of capital and land, nor with the principles of monarchical government. On behalf of the workers he advocated that

the government should fix a normal working-day, a normal day's work, and a maximum and minimum of wages.

Rodd, SIR JAMES RENNELL, born 1858, the son of an officer, held diplomatic appointments in Athens, Rome, Zanzibar, Abyssinia, Sweden, and was ambassador to Italy (1908-19), and British delegate to the League of Nations (1921, 1923). He has written half-a-dozen volumes of poetry, including *The Violet Crown*; and books on the Emperor Frederick, Raleigh, Greek folklore, and the history of the Moen. See his *Social and Diplomatic Memoirs* (1922-23).

Rodenbach, GEORGES (1855-98), born at Tournai, became a noted Belgian decadent writer, but spent his last years in Paris on the De Goncourt set; *Bruges la Morte* is his best-known book.

Rodentia (Lat. 'gnawers'), an order of Mammals more rich in species than any of the others, including among its familiar representatives squirrels, marmots, beavers, rats and mice, lemmings, porcupines, guinea-pigs, hares and rabbits. Most are terrestrial, and many are

Skull of Common Porcupine (*Hystrix cristata*): The lower jaw partly in section to show the lower incisor tooth.

burrowers, but a few are arboreal or even semi-aquatic. All are vegetarian, and gnaw their food. They are represented in all parts of the world.

Among the anatomical characteristics of Rodents may be noted the chisel-like edge of the incisor teeth, which wear away in front less rapidly than they do behind, where the enamel coating is thinner or absent; the reduction of the incisors to two above and two below, except in the hares and rabbits, in which there are four above; the fact that the incisors and sometimes the back teeth also are rootless, and continue growing from persistent pulps; the absence of canine teeth, and the presence of a large space between incisors and premolars; the condyle in which the lower jaw works is elongated from before backwards—an adaptation to the peculiar motion of the lower jaw characteristic of rodent gnawing; the cerebral hemispheres are smooth, and leave the cerebellum uncovered; the intestine, as in many herbivorous animals, has a large caecum; the uterus is two-horned, the placentation discoidal and decedant; the reproduction is in many cases very prolific.

Classification.—Sub-order Simplicidentata—with only one pair of upper incisors, having enamel only in front. This sub-order includes squirrels (*Sciurus*), flying squirrels (*Pteromys* and *Sciuropterus*), marmots (*Arctomys*), beavers (*Castor*), dormice (*Myoxidae*), rats and mice, voles, lemmings, muskrats (*Muridae*), pouched-rats (*Geomyidae*), the capybara (*Hydrochaerus*), porcupines (*Hystriidae*), agoutis (*Dasypracta*), guinea-pigs (*Cavia*). Sub-order Duplicitentata—with two pairs of incisors in the upper jaw, the second pair behind the first, the enamel extending round the teeth, but thinner posteriorly. This sub-order includes only the Picas or tailless hares (*Lagomys*) and the hares and rabbits (*Lepus*).

See Waterhouse, *Mammalia* (1848); Flower and Lydekker, *Mammals Living and Extinct* (1891); Beddard, *Mammalia* (1902); and the *Cambridge Natural History*.

Roderic, 'the last of the Gothi,' whose tragic death, coincident with the downfall of the Visigothic monarchy in Spain, has inspired poets and romancers (Scott, Southey, Geibel, Dahn) to throw round him a halo of glory. Next to nothing authentic is known about him; but according to the commonly accepted legend, he was the son of a noble who was blinded by King Witiza. A conspiracy having been formed against the hated Witiza by the clergy and the nobles of Roman blood, Roderic was elevated to the throne (710). The sons of Witiza, however, bided their time, meanwhile submitting to the usurper. At length certain malcontent nobles were engaged in a plot to dethrone Roderic by Count Julian, the governor of Genta (in North Africa), whose daughter had been outraged by the Visigothic king. Julian brought over with him a Moorish chief named Tank at the head of 12,000 men. Roderic met the invading army on the banks of the Guadalete, near Xeres de la Frontera, on 26th July 711. The battle raged six days; but the sons of Witiza, who commanded the wings of the Christian army, deserted during the contest, and the rout of the Visigoths was complete. Roderic either died on the field or was drowned in the Guadalete, whilst attempting to swim his horse across. A third version, however, relates that he escaped and passed the rest of his life as a pious hermit. By this victory the Arabs became masters of southern Spain. See Dr A. H. Knappe's monograph (1923).

Rodez, the capital of Aveyron dept. in S. France, stands on a bold bluff encircled by the Aveyron, 148 miles by rail N.W. of Montpellier. The Gothic cathedral (1277-1535) has a tower, 260 feet high, crowned by a colossal image of the Virgin. There are several mediæval houses, remains of a Roman amphitheatre, and a restored Roman aqueduct. Pop. 13,000.

Rodgers, JOHN, American naval officer, was born in Maryland, 11th July 1771, the son of a Scots colonel of militia. He was a captain in the merchant service by 1789, and in 1798 entered the navy. In 1805 he extorted from Tripoli and from Tunis treaties abolishing blackmail and forbidding the slavery of Christian captives. On 23d June 1812 he fired with his own hand the first shot in the war with Britain, and during the war he took twenty-three prizes. He died 1st August 1838.—His son, JOHN RODGERS (1812-82), a captain in the navy, captured a Confederate ironclad, and rose to be rear admiral (1869), and superintendent of the United States naval observatory (1877).

Rodin, AUGUSTE, French sculptor, was born of humble parents at Paris, 12th November 1840. At the age of 14 he began his art studies with Lecocq de Boislandran, but was refused admittance three times to the École des Beaux Arts. He worked in the studios of Buysse and Carrier-Belleuse, 1864-70, and, after following the latter to Brussels, collaborated with Van Rasboug, 1870-75, in some of the decorations of the Brussels Bourse. Rodin was much influenced by the work of Donatello and Michelangelo during an Italian tour in 1875, and also by the French cathedrals during a tour in 1877, the impressions of which he afterwards collected into a book. Thereafter, till his death, 17th November 1917, he lived at Meudon, near Paris, or in Paris itself. He paid several visits to London, and in 1914 made over 20 of his works to the British nation as a token of admiration for the British soldiers. In 1916 he gave all his remaining works to the French nation; all the finished pieces of statuary are now collected in his

Paris house, the Hôtel Biron. Rodin's principal works are: *L'Homme au Nez Cassé* (1864); *L'Âge d'airain* (1877), which caused a sensation at the Salon, the unknown sculptor being accused of having taken a cast from a living man; *Saint Jean-Baptiste* (1880); *La Porte d'Enfer*, after Dante's Divine Comedy, containing 186 figures, which occupied Rodin from 1880 for a great part of the rest of his life; *Le Baiser* (1898); *Ugolin* and *Le Penseur* (1904), which were all conceived originally as part of *La Porte d'Enfer*; *Les Bourgeois de Calais* (1884-95), a group of 7, with replicas at Calais, Paris, and London; the statue of Balzac (1898), also a commission but eventually not recognised by the Société des Gens de Lettres; the statue of Victor Hugo; and several busts, including those of M^{me} Rodin, Bastien-Lepage, Puvion de Chavannes, Pope Benedict XV., Clemenceau, and Mr Bernard Shaw. Rodin excels in the expression of action, his art being essentially dramatic. Sometimes his works seem unfinished, in that the hugeness of the conception makes adequate execution almost impossible, but usually the roughnesses and exaggerations deliberately emphasise what the sculptor considers significant. In the conveying of emotion by gesture Rodin is a master.

See the monumental work, *Rodin*, by L. Bénédite (1924), and the studies by Dirsks (1904), Manclair (Eng. trans. 1905), and Kahn (1909).

Rodney, GEORGE BRYDGES RODNEY, LORD, English admiral, born in February 1719, was the second son of Henry Rodney, a cadet of an ancient Somersetshire family, the elder branch of which had merged in that of Brydges, and was at that time represented by the first Duke of Chandos. Henry Rodney served for a few years as cornet of horse in the wars of William III. and Anne, and afterwards, settling at Walton-on-Thames, obtained an appointment under George I. as commander of one of the royal yachts. In this capacity he was noticed by the king, who offered to stand as godfather to his second son. The Duke of Chandos was the other godfather, and after the two boys were christened George Brydges. He received his early education at Harrow, which he quitted at the age of twelve to enter the navy as a 'king's letter boy.' After serving chiefly on the Newfoundland station he was made a lieutenant in 1739 in the Mediterranean; in 1742 he was promoted by Admiral Mathews to be post-captain, and was sent home in command of the *Plymouth*, a 61-gun ship. He afterwards successively commanded the *Sheerness*, *Ludlow Castle*, and *Centurion*, and in 1747 the *Eagle*, in which he had a brilliant share in Hawke's victory over L'Etendhere on 14th October. In 1748 Rodney went out in the *Rainbow* as governor of Newfoundland and commander-in-chief on that station, where he remained till 1752; in 1753 he commanded the *Fouquet*, and from 1754 to 1757 the *Prince George*. He was then appointed to the *Dublin*, one of the fleet under Sir Edward Hawke in the futile expedition against Rochefort, and in 1758 under Boscawen at the capture of Louisburg. In May 1759 Rodney was promoted to be rear-admiral, and in July commanded the small squadron which bombarded Havre and destroyed the flotilla of flat-bottomed boats collected for the proposed invasion of England. In October 1761 he was appointed commander-in-chief on the Leeward Islands station, where in the early part of 1762, in co-operation with the land forces, he captured Martinique, St Lucia, and Grenada. In October he was promoted to be vice-admiral, and returning to England in August 1763 was created a baronet, 21st January 1764. In November 1765 he was appointed governor of Greenwich Hospital, but in 1771 was recalled to active service,

was promoted to be admiral, nominated rear-admiral of Great Britain, and sent out as commander-in-chief at Jamaica. He hoped that he might succeed to the office of governor, which became vacant in 1773; but in his command he had shown an independence which was distasteful to Lord Sandwich, and his application was unsuccessful. In 1774 he returned to England, and for the next five years was left on half-pay, in very embarrassed circumstances, which compelled him to retire to France. It was not till October 1779 that he was again appointed commander-in-chief at the Leeward Islands, and on 29th December he put to sea with, in addition to the West Indian ships, a powerful squadron and a large convoy of store-ships for the relief of Gibraltar, then besieged by the Spaniards. On 9th January 1780, when broad off Cape Finisterre, he fell in with a convoy of Spanish store-ships under the escort of a 64-gun ship, all of which he captured. Passing Cape St Vincent on the 16th he met the Spanish squadron under Don Juan de Langara, which he attacked with a dash and vigour that carried everything before him. Seven ships out of eleven were taken or destroyed; the others managed to escape into Cadiz. Gibraltar was thus relieved without further difficulty than was caused by the weather; and on 13th February Rodney sailed for the West Indies. He had scarcely reached St Lucia, which he made his headquarters, when he had intelligence that the French fleet under the Count de Guichen had put to sea from Martinique. He immediately followed, and overtaking it on the 17th April fought an action in which, in despite of the fighting instructions, he attempted to concentrate his force on the rear of the enemy's line. Unfortunately his signals were not sufficiently clear, the flag-officers and captains did not understand what was proposed, and the clever attempt resulted in combative failure. During the following May he again twice met De Guichen, but without being able to bring him to a decisive engagement. In November he was nominated a K.B.; and in January 1781, in obedience to special orders from home, he seized on St Eustatius and the other Dutch settlements; but his health having broken down he was compelled to return to England a few months later. In December 1781 he again sailed for the West Indies; and, as before, shortly after arriving at St Lucia he had intelligence of the French fleet, under Count de Grasse, having sailed, with some 5000 troops on board, for Cape François, where it was to join a strong Spanish fleet for an attack on Jamaica. Abreast of Dominica Rodney came in sight of it, and, after an indecisive skirmish on the 9th April, had the good fortune, on the 12th April 1782, to bring it to close action; and being enabled, by the varying nature of the wind, to pass through the enemy's line, he gained a brilliant victory, rendered still more crushing by the success of a small squadron detached to look out for stragglers in the Mona Passage. The French loss in killed and wounded was extremely severe, and seven of their ships were captured, one of them being the *Ville de Paris*, with the Count de Grasse himself on board. The victory placed the English on a very different footing in the negotiations which had been already commenced; and the terms finally agreed on were much more favourable than might otherwise have been expected. But before the news reached England Admiral Pigot had been sent out by the new administration to supersede Rodney, who was looked on as a partisan of Lord Sandwich; and though an express was sent to stop Pigot on the way it failed to overtake him. Rodney returned to England, where—though raised to the peerage as Baron Rodney, with a pension of £2000 (see PENSIONS)—he was

but coldly received by the government. He had no further employment, and was allowed to live in comparative obscurity, which his shattered health perhaps rendered necessary. He died in London on 24th May 1792.

See his *Life* by General G. B. Mundy (2 vols. 1830), and Hainey's *Rodney* ('Men of Action' series, 1891).

Rodó, JOSÉ ENRIQUE (1872-1917), Spanish prose writer, an Uruguayan born at Montevideo, taught awhile, became a journalist, came to Europe as a correspondent for a periodical, and died at Palermo. He was author of *Ariel*, the appeal of an idealist for the cult of beauty and things spiritual as against ugliness and things material, *Motivos de Proteo*, a philosophic scheme with 'Self-renewal is Life' as motto, and *El Mirador de Próspero*, a collection of essays on economic and literary subjects.

Rodosto (anc. *Rhoadestos*), a town of European Turkey, stands on the north shore of the Sea of Marmora, 60 miles W. of Constantinople. It sends large quantities of fruits and vegetables to Constantinople. Pop. 42,000.

Rodríguez, or RODRIGUES, a hilly volcanic island (1300 feet), 380 miles E. by N. of Mauritius, of which it is a dependency, being one of the Mascarene group. The soil is fertile, and agriculture is the chief occupation. The exports are mainly animals and salt fish. Hurricanes often cause great damage to the island, which is encircled by a coral reef. It was discovered by the Portuguese in 1645, and after being held by the Dutch and the French, has been a British colony since 1814. The chief port is Port Mathurin. Owing to its isolation this island is particularly interesting to the botanist and the zoologist. Until near the close of the 17th century it was the home of the Solitaire (q.v.), now an extinct bird. Population, 6700; area, 40 sq. m. See Legnat's voyage thither (Hakluyt Society, 1891) and A. J. Bertuch, *The Island of Rodriguez* (1923).

Roe (*Capreolus caprea*), a small species of deer inhabiting Europe and some parts of western Asia, chiefly in hilly or mountainous regions which are covered with forests or with scattered bushes and heath. It is seldom found in the higher and more naked mountain tracts, the haunt of the stag or red deer. It was once plentiful in Wales and in the hilly parts of England, as well as in the south of Scotland, but is now very rare south of Perthshire. The roe is about 2 feet 3 inches in height at the shoulder. Its weight is about 50 or 60 lb. Its colour is a shining tawny-brown in summer, more dull and grizzled in winter; on the under surface and around the tail the colour is whitish, but there is considerable variety. The hair is longer than in many deer. The tail is very short, concealed among the hair. The antlers, which are peculiar to the male or *Roebuck*, are 8 or 9 inches long, erect, round, very rough, longitudinally furrowed; having, in mature animals, two or three tines or branches, which, as well as the tip of the horn, are sharp-pointed, so that the antlers form very dangerous weapons. The habits of the roe are somewhat like those of the goat, or even of the chamois. It keeps its footing on rocks with great security, bounds very actively, and takes great leaps. Its usual pace, when not very hard pressed, is, however, a kind of canter. It is not gregarious, not more than a buck and doe with one or two fawns being usually seen together. Contrary to what is usual among deer, the male and female remain attached during life. The voice of the roe deer, resembling that of a sheep, but shorter and more barking, is often heard through the night. The males are very combative at the breeding season. The roe browses on the tender shoots

of trees and bushes as well as on herbage, and is thus very injurious to young woods. It is never very thoroughly tamed, and when partially so is apt to become mischievous, and the male

Roe buck (*Capreolus caprea*).

dangerous. The venison is superior to that of the stag, but not equal to that of the fallow-deer. The horns are used for handles of carving-knives and similar articles.

Roe, RICHARD. See DOE, JOHN.

Roe, Sir THOMAS, diplomatist, was born near Winstead in Essex about 1568, studied at Oxford, and, after holding court appointments under Elizabeth and James I., was sent as a political agent to the West Indies, Guiana, and Brazil. In 1614 he sat in parliament, but from 1615 to 1618 was ambassador to the Great Mogul Jahangir at Agra. His journal of this mission was partly printed in Purchas and other collections. He was ambassador to the Ottoman Porte in 1621-28, afterwards represented England in Poland, Denmark, and elsewhere, and died in 1644.

Roeback, JOHN ARTHUR, English politician, was born at Madras in December 1802, but passed his youth in Canada. Coming to England in 1824, he was in 1831 called to the bar at the Inner Temple, and in 1832 elected as a Radical reformer for Bath to the House of Commons. He represented Sheffield from 1849 to 1868, and again from 1874 till his death on 30th November 1879. The vigorous nature of his political warfare earned him the popular nickname of 'Teur'on.' His greatest political triumph was the moving of a motion for inquiring into the condition of the army before Sebastopol in January 1855, which he carried by a large majority, causing the fall of the administration of the Earl of Aberdeen. He was appointed chairman of the committee which conducted the inquiry moved for. During the civil war in America he displayed a strong leaning towards the Confederates. He supported the Earl of Beaconsfield's policy during the Eastern crisis in 1877-78, and in 1879 was made a member of the Privy-council. He was the author of a work on the *Colonies of England* (1849), and *The Way Ministry of 1830* (1852). See his *Life and Letters* by Leader (1897).

Roormond, an old town in the Dutch province of Limburg, at the junction of the Roer and the Meuse (Meuse), 29 miles by rail N. by E. of Maastricht. The cathedral (1218) is one of the finest Romanesque churches in the Netherlands. The church of St Christopher contains good paintings by Dutch masters. Principal industries are weaving woollen cloths and cottons and making paper. During the middle ages Roormond was on several occasions besieged and taken; its walls were demolished in 1819. Pop. 14,000

Roeskilde, a city on the Danish island of Zealand, is situated at the southern end of the Roeskilder Fjord, 20 miles by rail W. by S. of Copenhagen. In the middle ages this city, founded in 980, was the capital of the Danish kings and the seat of powerful bishops. The cathedral, built in the middle of the 13th century, contains the tombs of most of the kings of Denmark. Here peace was signed between Sweden and Denmark on 8th March 1658. Pop. 13,000 (formerly 100,000).

Roe-stone, a name locally given to those lime-stones which are formed of small globules like the roe of fishes. It has been translated into the scientific term *Oolite* (q.v.).

Rogation Days, the Monday, Tuesday, and Wednesday before Ascension-day, so called because on these days the Litany (q.v.) is appointed to be sung or recited by the clergy and people in public procession. The practice of public supplications on occasion of public danger or calamity is traceable very early in Christian use; but the fixing of the days before Ascension for the purpose is ascribed to Mamertus, Bishop of Vienne, in the middle of the 5th century. In England the usage dates from perhaps the 7th century; after the Reformation the recitation of the Litany upon these days was discontinued; but a memorial of the old processions long survived in the so-called Perambulation of Parishes (see BOUNDS, BEATING OF THE).

Roger I., count of Sicily, the youngest of the twelve sons of Tancred de Hauteville of Normandy, was born in that duchy in 1031. When twenty-seven years of age he joined his famous brother Robert Guiscard (q.v.) in South Italy; but at first he seems to have fought against Robert more than he helped him. At length they became reconciled, and Roger helped Robert to complete the conquest of Calabria. In 1060 Roger was invited to Sicily to fight against the Saracens; he took Messina, and settled a garrison there. Everywhere the Normans were welcomed by the Christians of Sicily as their deliverers from the Moslem yoke, and they won town after town, until in 1072 the Saracen capital, Palermo, was captured. Robert then invested Roger with the countship of Sicily. Count Roger spent the rest of his life, apart from his numerous expeditions undertaken for the support of his brother, in completing the conquest of Sicily, which was finally effected in 1091. Already as early as 1060 Duke Robert had given his brother the half of Calabria, with the title of count. After Robert's death (1085) Roger succeeded to his Italian possessions, and became the head of the Norman power in southern Europe. Pope Urban II. granted him special ecclesiastical privileges, such as the power to appoint the bishops, and made him papal legate of Sicily (1098). Roger died at Miloto, in Calabria, in June 1101. See SICILY.

Roger II., king of Sicily, the second son of Count Roger I., was born in 1097, and by the death of his elder brother Simon in 1105 became count of Sicily. On the death (1127) of Duke William of Apulia, grandson of Robert Guiscard, his duchy passed to Roger, who thereupon proceeded to weld together a strong Norman kingdom in Sicily and South Italy; the Antipope Anacletus crowned him king of Sicily, Apulia, and Calabria in 1130. He next added to his dominions the Norman principality of Capua (1136), the duchy of Naples, and the territories of the Abruzzi (1140). In the year prior to this last acquisition he managed to take prisoner Pope Innocent II., with whom he concluded an advantageous bargain: Innocent recognised him as king of Sicily, whilst Roger acknowledged Innocent as pope, gave him his liberty, and held his kingdom as a fief of the holy see. The Byzantine emperor Manuel having

insulted Roger's ambassador, Roger's admiral, George of Antioch, ravaged the coasts of Dalmatia and Epirus, took Corfu, and plundered Corinth and Athens (1146). He carried off silk-workers from the Peloponnesus to Sicily, and so introduced that industry into the kingdom. Roger then crossed the Mediterranean (1147) and won a large province from the Saracens in North Africa—Tripolis, Tunis, and Algeria. His court was one of the most magnificent in Europe; he was tolerant to all the creeds of the various peoples under his rule; his government was firm and enlightened; his name a terror to both Greeks and Moslems. Roger died in February 1154. See SICILY; and *Roger the Great*, by E. Curtis (1913).

Roger of Wendover (d. 1236), Benedictine prior of St Albans, completed the work of Matthew Paris (q.v.).

Rogers, JAMES EDWIN THOROLD, economist, was born at the village of West Moon, Hampshire, in 1823, and educated at King's College, London, and Magdalen Hall, Oxford, graduating with a first-class in 1846. At first an ardent Puseyite, he took orders, but soon returned to Oxford and became a successful 'conch', and renounced his orders formally, together with Dr Congreve and Leslie Stephen, after the Clerical Disabilities Act of 1870. In 1862 he was elected professor of Political Economy, but made so many enemies by his outspoken zeal for reforms that he was not re-elected in 1868, nor until the death of Bonamy Price in 1888. An advanced Liberal in politics, he represented Southwark, 1880-85, and Brompton, 1885-86. He died October 12, 1890. His greatest work is his painful and laborious *History of Agriculture and Prices in England* (8 vols. 1866-93), and its abridgment, *Six Centuries of Work and Wages* (1885). Besides these he wrote a study on Cobden (1873), edited the *Speeches* (1868) and *Public Addresses of Bright* (1879), the *Wealth of Nations* (2 vols. 1880), and the *Collection of Protests of the Lords* [1624-1874] (3 vols. 1875).

Other books are *Education in Oxford* (1861); *Historical Gleanings* (2 series, 1869-70); *The First Nine Years of the Bank of England* (1887); *The Economic Interpretation of History* (1888); and, ed. by his son, *The Industrial and Commercial History of England* (1892).

Rogers, JOHN, the first of the Marian martyrs, was born near Birmingham in 1505, graduated in 1525 from Pembroke Hall, Cambridge, was a London rector (1532-34), and then lived for some years abroad, at Antwerp and Wittenberg, where he embraced the Reformed doctrines. He prepared a revised translation of the Bible (q.v., p. 127), which was published as 'Matthew's Bible' in 1537, and, returning to England in 1548, preached at St Paul's Cross in 1553, just after Queen Mary's accession, against Romanism. After a long imprisonment he was tried as a heretic, and burned at Smithfield on 4th February 1555. See his *Life* by Colonel J. L. Chester (1861).

Rogers, SAMUEL, the poet, was born at the suburban village of Stoke Newington on 30th July 1763, the third son in a family of nine. His father, a City banker, was a Whig and dissenter, a member of the congregation of Dr Price (q.v.); his mother, Mary Radford, was the great-granddaughter of Philip Henry. After a private education, at sixteen or seventeen he entered the bank, in 1784 was taken into partnership, and on his father's death in 1793 became head of the firm. His taste for literature and for the company of literary men awoke at an early period, and one day with a friend he had gone to call upon Dr Johnson at his house in Bolt Court, but his courage failed him when his hand was on the knocker. In 1781 he contributed eight short essays to the *Gentleman's Magazine*;

next year wrote a comic opera, containing a score of songs; and in 1786 (the year of Burns's first volume) published *An Ode to Superstition, with some other Poems*. In 1792 appeared *The Pleasures of Memory*, on which his poetical fame was chiefly based, and which in 1816 reached a nineteenth edition (more than 23,000 copies). There followed, 'written with laborious slowness,' *An Epistle to a Friend* (Richard Sharp, 1798), the fragmentary *Voyage of Columbus* (1812), *Jacqueline* (1814, bound up with Byron's *Lara*), and the 'inimitable' *Italy* (1822-28). The last, in blank verse, proved a monetary failure; but the loss was recouped by the splendid edition of it and his earlier poems, brought out at a cost of £15,000 (2 vols. 1830-34), with 114 illustrations by Turner and Stothard.

Meanwhile he had left the old home on Newington Green, and in 1803 (in which year, with £5000 a year, he withdrew from the bank as a sleeping partner) had given up the chambers in the Temple, and settled down finally to bachelor life in his exquisite house, 22 St James's Place, looking into the Green Park. He had had his affluence of the heart, had proposed, indeed, to a daughter of Banks the sculptor. She refused him, and left him free to cultivate his muse and caustic wit, to raise breakfast-giving to a fine art, to make little tours at home and on the Continent, and to gather an art-collection which sold at his death for £50,000. With Rogers one cannot help harping upon money, for he was rich as no poet perhaps before or after him. At least he made a good use of his riches, for he was quietly generous to Moore and Campbell, and others, unknown ones, whom it was no such credit to have aided. But with the kindest heart he had the unkindest tongue. 'I have a very weak voice,' he explained once to Sir Henry Taylor; 'if I did not say ill-natured things no one would hear me.' With which, however, Campbell's saying should be coupled: 'Borrow five hundred pounds of Rogers, and he will never say a word against you till you want to repay him.' Anyhow it has come to pass that 'melodious Rogers,' whom Byron ranked above Wordsworth and Coleridge, as we too might rank him if only his works had perished, is better remembered to-day by a few of those ill-natured things (e.g. by his witty couplet upon Ward; see EPIGRAM) than by his poetry, which, chaste though it be, and elegant and cultured, with 'no such thing as a vulgar line in it,' is dead and mummified. It is no more a pleasure of memory, but unread, not even forgotten. One is reconciled somewhat to such oblivion by remembering how, when in his old age Fanny Kemble used to go and sit with Rogers, she never asked what she should read to him without his putting into her hands his own poems, which always lay by him on his table. For this was the Rogers who had announced his intention of being 'read to, when old and bedridden, by young people—Scott's novels perhaps.' There is not much more to tell of him—the bank-robbery (£47,000, 1844); the proffer by Prince Albert of the laureate-ship (1850); the street accident—knocking down by a carriage (1850)—which crippled him for the rest of his life; and the peaceful ending of that life (*ret.* ninety-two) on 18th December 1855. He is buried at Hornsey.

See Alexander Dyce's *Recollections of the Table-talk of Samuel Rogers* (1856); *Recollections by Rogers*, edited by his nephew William Sharp (1859); Hayward's article in the *Edinburgh Review* for July 1856 (reprinted in his *Essays*, 1879); F. W. Claydon's *Early Life of Rogers* (1887) and *Rogers and his Contemporaries* (2 vols. 1889), and R. E. Roberts's *Samuel Rogers and his Circle* (1910).

Roget, PETER MARK, was born in London in 1779, the only son of a Genevan who had settled as

minister of a French church in London and married the sister of Sir Samuel Romilly. He was educated at Edinburgh, became physician to the Manchester Infirmary in 1804, and in 1808 settled in London, where he became physician to the Northern Dispensary; F.R.S. (1815), and afterwards for over twenty years its secretary; Fullerian professor of Physiology at the Royal Institution; and an original member of senate of the University of London, surviving till 17th September 1869. He wrote one of the 'Bridgewater Treatises,' *On Animal and Vegetable Physiology considered with Reference to Natural Theology* (1834), and the more famous *Thesaurus of English Words and Phrases* (1852), passed through 28 editions in his lifetime.

Rogue-money, an assessment formerly levied on every county in Scotland 'for defraying the charges of apprehending criminals, or subsisting them when apprehended, and of carrying on prosecutions against them.' This tax was first imposed by statute, 11 Geo. I. chap. 26, on the narrative that criminals were in the habit of escaping punishment for lack of the funds necessary to bring them to justice. The freeholders in each shire were directed to fix the assessment at any of the head courts yearly, and to appoint collectors. By 31 and 32 Vict. chap. 82 rogue-money in the shires was abolished, and in lieu thereof power was conferred on the Commissioners of Supply to levy by rate a 'County General Assessment.' By the Local Government (Scotland) Act, 52 and 53 Vict. chap. 50, sect. 11, this power of the Commissioners of Supply is now vested in the locally elected county councils. It is to be observed, however, that the repealed portions of 31 and 32 Vict. chap. 82 do not include sect. 10, which reserves the existing right of any burgh to levy rogue money.

Rohan, an ancient Breton family of princely rank, descended in the male line from the dukes of Brittany, the name taken from the village of Rohan in the department of Morbihan. Its motto was characteristic of its pride: 'Roy ne puyx, Duc ne daygne, Rohan says.' The family still flourishes in the line of Rohan-Guéméné-Rochefort, naturalised with princely rank in Austria. The line of Rohan-Soubise became extinct in 1787, that of Rohan-Gié in 1638. The founder of the family was Alain I., fourth son of the Vicomte Fudon de Pothoët, who became Vicomte de Rohan in 1128. Under Charles IX. in 1570 the domain of Guéméné was formed into a principality for Louis Rohan VI., whose son Louis de Rohan-Guéméné was made in 1588 by Henry III. Duc de Montbazan. Both the latter and his son Hercule (died 1634) bore arms against the League. The famous beauty, wit, and political intriguer, the Duchesse de Chevreuse (died 1679), was a daughter of Hercule. Louis, Prince de Rohan-Guéméné (born 1635), lost the favour of Louis XIV. by his dissolute life, and died on the scaffold in 1674 for treasonable dealings with the Dutch.

LOUIS RENÉ EDOUARD, PRINCE DE ROHAN-GUÉMÉNÉE, born 25th September 1734, embraced the clerical life in spite of dissolute morals and an extravagant love of luxury, and at an early age became coadjutor to his uncle the Bishop of Strasbourg. In 1772 he was sent as a special minister to Vienna. His habits were displeasing to Maria Theresa, and he ruined himself at the French court by slanderous gossip about Marie Antoinette. He was recalled in 1774, and, although with grudging, made grand-almoner in 1777. Next year came a cardinal's hat, through the influence of Stanislaus Poniatowski, king of Poland; and a year later the succession to the bishopric of Strasbourg, held by three members of his family before him. His eagerness to recover his footing at court made him an

easy victim to the schemes of Cagliostro and the adventuress Lamoignon, and their clumsy forgeries and personations were enough to make him purchase the famous Diamond Necklace for the queen. As soon as the plot was discovered the cardinal was sent to the Bastille, but was acquitted by the Parlement of Paris, 31st May 1786. He found himself for the moment a hero of the mob, was elected to the States-general in 1789, but refused to take the new oath to the constitution in January 1791, and retired to Ettenheim in the German part of his diocese, where he died, 17th February 1803.

See DIAMOND NECKLACE, and books enumerated thereat; also the far from trustworthy *Mémoires inédits du Comte de Lamoignon-Faloux* (edited by Louis Lacour, 1858), and G. C. D'est Ange, *Marie Antoinette et le Procès du Collier* (1889); the *Mémoires* of Rohan's secretary, the Abbé Georgel, as well as the books by Benigne and Madame Campan.

With Victor Louis Mériadec, Prince de Rohan-Guéméné, Duc de Montbazan and Bouillon, who died in 1846, ended the direct main line. He was succeeded by his two nephews, sons of a younger branch of the line Guéméné, that of Rohan-Rochefort, who had been adopted in 1833 by his brother Jules Armand Louis (died 1836).

The line Rohan Gié, which sprang from that of Guéméné, was founded by Pierre de Rohan de Gié (1453 1513), marshal and tutor of Francis I. His son fell at Pavia in 1525; his grandson, René I., at Metz in 1552. The latter was married to Isabella d'Albret, great-aunt of King Henry IV., whence the Calvinism of the family. René II. (1550 86) married in 1575 the celebrated poetess, Catherine de Parthenay, heiress of the house of Soubise.—Their son Henri, Duc de Rohan-Gié, Prince of Leon, was born 21st August 1579 at the castle of Blain in Brittany, and at sixteen came to the court of Henry IV., with whom he was ever an especial favourite. He was made in 1603 Duc de Rohan and a peer of France, and in 1605 he married the daughter of Sully. After the king's murder—a fatal blow to his hopes—he became one of the chief leaders of the Huguenot party in France, and, when all endeavours to bring about a peaceable settlement had come to nothing, took up the sword, fortified the places in Guienne, held Montauban against the king, and at last forced him in the peace of 1622 into a confirmation of the Edict of Nantes. Thereafter he took his share in all the tortuous intrigues of the time, fighting now for his king, now against him, ever holding up the religious cause, alike in times of open warfare and hollow peace. After the surrender of La Rochelle (1628) a price was set on his head, and he made his way to Venice, but soon after was called on by Richelieu to serve his king in the Valtelline, out of which he speedily cleared both the Imperialists and the Spaniards. He next carried his sword to Bernhard of Saxe-Weimar, but received a wound at Rheinfelden on the 28th February 1638, of which he died at Konigsfeld on the 13th April. But his name survives best in his admirable *Mémoires*, three books of which (1644) embrace the civil wars, the fourth (not published till 1758) the Valtelline campaign. They may be found in Michaud and Poujoulat's collection.

See the works by Fauvelot du Too (Paris, 1667); Schybergson (*ib.* 1880), H. De La Garde (*ib.* 1884); Bähring, *Venedig, Gustav Adolf, und Rohan* (Halle, 1885); Langel, *Henri de Rohan, son rôle politique et militaire sous Louis XIII.* (Paris, 1889); the *Edinburgh Review* for April 1890; Veraguth, *Hercor Rohan* (1894).

His daughter, Marguerite de Rohan, brought the great possessions of the house in 1645 to her husband, Henri de Chabot, Marquis de Saint-Anlaye, who thereupon assumed the name of Rohan.

See SOUBISE; also De La Chenaye-Desbois, *Genealogie des Houses Rohan* (Pargne, 1872).

Rohilkhand, a division of the United Provinces of Agra and Oudh, has an area of 10,800 sq. m. and a pop. of 5,200,000.

Rohillas were Afghan Pathans who rose to power in Rohilkhand, India, about the middle of the 18th century. The Mahrattas on one side and Shuja ud-Daula of Oudh on the other pressed them hard; at last Shuja, with the help of British soldiers lent to him by Warren Hastings, succeeded (1773-74) in subduing them. See Sir John Strachey's *Hastings and the Rohilla War* (Oxford, 1892).

Rohlfs, GERHARD, German traveller in Africa, was born at Vegesack near Bremen on 14th April 1832, studied medicine at Heidelberg, Würzburg, and Göttingen, and joined (1855) the Foreign Legion serving in Algeria. Having learned Arabic and made himself thoroughly familiar with Mohammedan customs, he set off (1861) for Morocco, travelled through that country under the protection of the Grand Sherif, and was exploring the Wady Draa in the Sahara (1862) when he was attacked by his own guides, plundered, and left for dead in the desert. Two marabouts found him and carried him back to Algeria. In 1864 he again visited the Sahara, getting to Tuat and Ghadames; in 1865 he was in Fezzan and Tibesti; in 1866 in Bornu, whence he made for the Benue, and so reached the Niger. He accompanied the British expedition to Abyssinia in 1868; and was then sent to carry presents from the king of Prussia to the sultan of Bornu. In 1873-74 he was commissioned by the Khedive of Egypt to lead an expedition to the oasis of Siwa (Jupiter Ammon) in the Libyan Desert. The German government in 1878 sent him to carry presents from the emperor to the sultan of Wadai; but the expedition was attacked and driven back by Arabs in the oasis of Kufra. The last mission of Rohlfs was from the German emperor to Abyssinia in 1885. He died 2d June 1896. He wrote several books on his journeys.

Rohtak, a town of British India, in the Punjab, 42 miles NW. of Delhi. Tarbans are manufactured. Pop. 25,000.

Rokitansky, KARL, BARON VON, founder of the school of pathological anatomy at Vienna, was born at Königgratz in Bohemia on 19th February 1804, studied medicine at Prague and Vienna, in 1828 was appointed assistant to the professor of Pathological Anatomy in the university of the latter city, and in 1834 succeeded him. He likewise held the offices of prosector at the city infirmary, legal anatomist to the city, and medical adviser to the ministry of education and public worship. In 1869 he was made president of the Austrian Academy of Sciences. He retired from work in 1875, and died on 23d July 1878. Although Rokitansky agreed with the old humoral pathologists in so far that he regarded the changes of the blood as the chief immediate causes of disease, he laid the principal stress of medical study upon morbid anatomy, post-mortem dissection, and observation. He stands pre-eminent amongst German medical teachers as the one who established pathological anatomy as the basis of all original scientific inquiry in the domain of medicine. His teachings were published in the great work *Handbuch der pathologischen Anatomie* (5 vols. 1842-46; 3d ed. 1855-61; Eng. trans. of Sydenham Society, 4 vols. 1849-52), and in *Memorials of the Vienna Academy of Sciences*. See an anonymous Biography (Vienna, 1874).

Roland (Ital. *Orlando*, Span. *Roldán*), the most prominent hero in the Charlemagne legend, is a figure in history as well as in poetry and fable, though all that we know of him is contained in one line of Eginhard's *Vita Karoli*,

chap. ix., and that simply records his name, Hrodlandus, his rank of prefect or warden of the march of Brittany, and his death at the hands of the Gascons in a valley of the Pyrenees. Such is the acorn from which a whole forest of romance has sprung up. According to the *Annals* (commonly attributed to Eginhard, but by some to Angilbert, who died fifteen years before they end), Charlemagne was invited in 777 to take possession of Saragossa and other cities in Spain by Ibn al Aribi, leader of the revolt against the Khalif Abd-er-Rahman, and in 778 crossed the Pyrenees into the territory of the Gascons, attacked and took Pamplona, the stronghold of the Navarrese, and advanced to Saragossa, and having received the submission of Ibn al Aribi and his friends, and taken hostages of them, returned the way he came. According to other accounts the Saracens played him false, and a rising of the Saxons compelled him to hasten home. Al Makkaui merely says that after warring for some time with Abd-er-Rahman he sent him an embassy proposing an alliance and friendship, and that peace was concluded between them. At any rate it is certain that Charles made but a short stay in Spain, that on his way back he levelled the walls of Pamplona to the ground, and that about 25 miles north-east of it the rearguard of his army was annihilated by the Gascons at Roncevaux. The battlefield is a small oval plain, evidently an old lake-bed, shut in all round, except on the south where the waters escaped, by steep mountain ridges clothed from base to summit with thick beech woods. To the north there is a slight depression where, by the Col of Ibañeta, a path crosses the crest of the Pyrenees and descends the Val Carlos to St Jean-Pied-de-Port. The features of the spot are faithfully given in a few words by Eginhard. As the army, by reason of the narrowness of the place, was marching in extended order, the Gascons, from an ambush in the heights, rushed upon those guarding the rear, hurled them into the valley beneath, and there slew them to a man. Roncevaux is in fact a natural trap, and it says little for Charles as a general that he should have ventured into it without first securing the heights and scouring the woods; for when Roland, in the *Chanson*, thinks of it, it is too late. He was in a hostile country, made so by his own acts. Eginhard may talk of the perfidy of the Gascons, and poets sentimentalise over the *dolorosa rotta*, but history and justice will call it a merited retribution for overhearing militarism, and the proper punishment of insolent contempt for a weak adversary.

Naturally, the tragic character of the disaster, and the reverse to the mighty king of the Franks at the close of what was looked upon as a holy war, made a deep and wide-spread impression. Upon himself the effect, the *Annals* say, was that it clouded the success of his expedition, and there can be no doubt that already in his lifetime it was a theme with the popular minstrels far and wide. In the middle of the 9th century the biographer of Louis held it needless to mention the names of those who fell, *quia vulgata sunt*. In course of time the story underwent modifications in the hands of the poets. Everything in it was magnified. The expedition became a campaign lasting twice as many years as it had occupied months; the disaster was made a defeat of vast proportions, accounted for by treachery, the traitor Ganelon being invented for that purpose; the Basques were turned into Saracens; and for further dramatic effect Charlemagne, who was but thirty-six, was represented as a venerable old man with a snow-white beard, and Roland as his nephew. M. Bédier regards the *Chanson de Roland* and the other Charlemagne epics as separate literary creations, not products of evolution through oral tradition.

The oldest form in which we have the *Chanson de Roland* is that of the MS. in the Bodleian Library, Oxford, written presumably towards the end of the 12th century; but this is evidently by no means its oldest form as a consecutive poem. It is in the language of northern France, the language of the trouvères, but there is no good reason for assigning it to any one province. The best, and most likely the oldest, part of the poem is that which deals with the combat at Roncesvalles, Roland's refusal, until too late, to sound his horn, the deeds and deaths of the poets one by one, and of Roland last of all. The opening portion, the despatch of Ganelon at Roland's suggestion as envoy to the Saracens, his anger and betrayal of Roland in revenge, and the concluding part, the vengeance of Charlemagne, and the trial and death of Ganelon, probably came later. There can be little doubt that the episode of the Emir Baligant was a comparatively late addition.

Besides the Oxford MS. there are half-a-dozen others ranging from the 13th to the 16th century. In the Oxford MS. the assonant rhyme is maintained throughout, the same assonance being kept up to the end of each break or *laisse*. In the later MSS. the assonance is turned into full consonant rhyme, and the poem expanded to twice or thrice its former length. A very close German version, the *Ruolandes Liet*, shows that early in the 12th century the chanson had passed out of its native country and language; and it is almost as closely followed in the Icelandic *Karlsmagnus Saga* of the 13th. The *Chanson de Roland* is the foundation of the Charlemagne legend. Charles's wars and quarrels with his vassals would no doubt of themselves have furnished themes for the jongleurs, but the legend, culminating in the Morgante of Pulci and the Orlando of Boiardo and Ariosto, is the outcome of the story of Roland and Roncesvalles.

The following are the printed editions of the *Chanson de Roland*: From the Oxford MS., by Francisque Michel (Paris, 1837); text, with translation, by F. Genin (Paris, 1850); the Oxford text, ed. Müller (Gott. 1851; reprinted with additions, 1863, 1878); 2d ed. of F. Michel's, with text of 13th-century MS. in the Bib. Nat. added (Paris, 1867); *Roncesval*, Oxford text E. Boehmer (Halle, 1872); MS. of Ldk of St Mark, Venice, fac-simile by L. Kolbing (Heilbronn, 1877); Oxford MS., ed. by E. Stengel, with a photograph fac-simile (Leipzig, 1909); Text, with translation in assonant rhyme, Petit de Julleville (Paris, 1878); Text, with translation, commentary, notes, &c., by Léon Gautier (often reprinted). There are other translations by Jonain, Lehugeur, St Albin, Jubert, Baron d'Avril (1865, 1877), and Fabre (1902). The *Ruolandes Liet* was printed in 1727, and again by W. Grimm in 1838, and by Karl Bartsch (1874); and there is a translation by W. Hertz (1861). Mrs Marsh in 1851 translated Vite's epitome of the poem; O'Hagan produced a scholarly metrical version (2d ed. 1883), as did Fabillon (New York, 1885) and Way (1913); Butler's (1904) is in prose; Scott Moncrieff's (1919) in *laissez*. See two works by G. Paris (1900-5), Bédier, *La Chanson de Roland* (1922).

Roland de la Platière, JEAN MARIE, and his greater wife, MADAME ROLAND (née Marie-Jeanne or Manon-Philippon), are among the most memorable martyrs of the French Revolution. Roland was born of a decayed legal family at Thizy, near Villefranche-sur-Saône, in 1734. He made his way unaided, and had risen to be inspector of manufactures at Amiens, when in January 1776 he made the acquaintance of his gifted wife. She was twenty years his junior, having been born at Paris, 17th March 1754, daughter of an engraver, who ruined himself by unlucky speculations. From the first an eager and imaginative child, she read everything, even heraldry, and Plutarch made the young idealist a republican for life. At eleven she

went for a year into a convent to prepare for her first communion, next passed a year with her grandmother, and then returned to her father's house, where she read Buffon, Bossuet, and Helvétius, and at length found her gospel in the writings of Rousseau. Her mother died in 1775, and the girl, solitary and poor, and soured to her father by his misconduct, at length in February 1780 married the estimable Roland. He was over forty, thin, yellowish, careless in dress, abrupt and austere in manners, solid and well-informed indeed, but dry, unsympathetic, and addicted to talking about himself. They lived at Amiens, where her only child, a daughter, Endora, was born (Oct. 1781); and next at Lyons, and travelled in England and Switzerland. The Agricultural Society of Lyons charged Roland to draw up its *cahier* for the States-general, and in February 1791 he went to Paris to watch the interests of its municipality, returned to Lyons in September, but came back to Paris before the close of the year. It was now that Madame Roland became queen of a coterie of young and eloquent enthusiasts that included all the famous and ill-fated leaders of the Gironde, Bissot, Buzot, Pétion, and at first even Robespierre and Danton. In March 1792 Roland became minister of the Interior, and his stiff manners, round hat, and unbuckled shoes struck dismay into the court. Three months later he was dismissed for his remonstrance to the king, who had refused to sanction the decree for the banishment of non-juring priests. It was Madame Roland's vigorous pen that wrote this letter, as indeed she wrote most of the papers that her husband signed. He was recalled after the king's removal to the Temple, made himself hateful to the Jacobins by his protests against the September massacres, and took his part in the last ineffectual struggle of the Girondists to form a moderate party. On 22d January 1793, just after the king's execution, he resigned. It was in the last days of the Gironde that the reciprocal affection between Madame Roland and Buzot crossed the indefinite bounds that separate friendship from love. But her Spartan soul sacrificed its passion to duty, and she made a confidant of her husband. On 31st May the tocsin announced the proscription of the Twenty-two. Roland had been arrested, but escaped and fled to Rouen; Buzot and some of the others fled to Chen to organise insurrection, but in vain; next day she herself was seized and carried to the Abbaye. Set at liberty two days later, she was arrested anew and taken to Sainte-Pélagie. In her five more months of prison she wrote her unfinished *Mémoires*, furtively, with a swiftly flowing pen, on sheets of coarse gray paper given her by a kindly turnkey. The approach of death unsealed her lips, and (22d June to 7th July) in four letters to Buzot, strangely discovered in 1863, she spoke out a love that could never now come into conflict with duty. On the 8th November 1793 she was carried to the guillotine along with a trembling printer of assignments, whom she asked Sanson to take first to save him the horror of seeing her head fall.—'You cannot,' said she, 'refuse the last request of a woman.' On the scaffold, as she looked up at the statue of Liberty, she exclaimed, 'O Liberté, comme on t'a jouée!' or as it is still more commonly given, 'O Liberté, que de crimes on commet en ton nom!' She had often said her husband would not long survive her; on hearing of her fate he ran himself through with his sword-stick near Rouen.

Madame Roland's *Mémoires*, a serene and delightful revelation of her youth in a series of charming glimpses, were first published in 1820. In 1864 they were printed in their entirety, and edited by Dauban and by Faugère. The best edition is that of Perroud (1905). But in writing

she is best and most natural in her letters, as in those to her future husband, the series to Bosc, those to Bancel des Issarts, the four to Buzot, and the exquisitely simple letters to her two school friends, Henriette and Sophie Canuet. Her *Letters* were collected by Dauban (2 vols. 1867), and by Perroud (2 vols. 1900-2), who also edited the *Lettres d'Amour* of the Rolands (1909). See the studies by Dauban (1864), Mathilde Blind (1886), J. A. Taylor (1911); Lamy, *Deux Femmes Célèbres* (1884); Austin Dobson, *Four Frenchwomen* (1890); Sauter-Bouve, in *Nouveaux Lendis*, and in *Portraits de Femmes*: Una Birch, *Mme. Roland* (1917).

Rolf. See NORTHMEN, NORMANDY.

Rolland, ROMAIN, was born at Clamecy in central France on 29th January 1866. Educated at Paris and Rome, he devoted himself to the fine arts, taking special interest in the history of music and the theatre, and lecturing as professor of the History of Art at the Sorbonne. His works include historical plays (*St Louis, Le 14 Juillet, Danton*, &c.); monographs on Handel, Beethoven, Hugo Wolf, Millet, Michelangelo, Tolstoy; critical essays on the drama and opera; socialist and pacifist writings; but his most notable production is a novel-cycle, *Jean Christophe*, in three parts and ten volumes (1904 *et seq.*; Eng. trans. 4 vols.), the comprehensive plotless story of the development of a musician of genius, a hero 'with a pure heart and unclouded vision,' revolted by the shams and compromises of conventional morality. This colossal work won immediate recognition by the subtlety and delicacy of its psychological analysis, its fine courage, and its vivid style. See *Rolland, l'Homme et l'Œuvre*, by P. Seippel (1913); and Stefan Zweig's Study (1921).

Rolle, RICHARD. See HAMPOLE.

Roller (*Coraciidae*), a family of Picarian birds characteristic of the Ethiopian and Oriental regions, although the common Roller is extensively distributed in the Palaearctic region and a few species enter the Australian region. None are found in the New World. Madagascar possesses three species peculiar to itself, and so different from one another that they are regarded as types of different genera, and so different from other rollers that they are grouped into a separate sub-family, Brachypteraciinae: they are named ground-rollers, and are nocturnal in habit. An Indian species, *Eurystomus orientalis*, is also nocturnal. The Common Roller (*Coracias garrula*) is an autumn or more rarely a spring visitor to the British Isles; and about one hundred have been recorded since the first one was noticed by Sir Thomas Browne in 1644. Some have visited the Orkneys

countries bordering on the Mediterranean it is very abundant. It ranges through Asia to Omsk in Siberia and to North-west India. In winter it extends its migrations to Natal and the Cape. In size it is about a foot long. The general colour is light bluish green; the mantle is chestnut-brown; the wings and rump are adorned with beautiful azure blue. The female resembles the male in plumage. Nesting takes place in the woody haunts in May. The nest, which is made in a hollow tree or wall, is built of a few chips, or of roots, grass, feathers, and hair, according to circumstances. The eggs are five or six in number and are of a glossy white colour. The food consists of beetles and other insects captured on the ground. The name 'Roller' is given to the bird on account of its varied and unsteady flight and the habit the male has, during the breeding season, of indulging in extraordinary tumbling antics, and turning somersaults in the air.

Rolleston, GEORGE, was born at Maltby in Yorkshire, July 30, 1829. He had his schooling at Gainsborough and Sheffield, next entered Pembroke College, Oxford, took a classical first-class in 1850, and was elected Fellow of his college the next year. He studied at St Bartholomew's Hospital, and was appointed in 1855 a physician to the British Civil Hospital at Smyrna. Returning to England in 1857, he was made physician to the Radcliffe Infirmary at Oxford, and somewhat later Lee's reader in Anatomy. In 1860 he was appointed Linacre professor of Anatomy and Physiology, became F.R.S. in 1862, Fellow of Merton College in 1872, and died June 9, 1881. His *Forms of Animal Life* (1870) gave him a high reputation, confirmed by his valuable dissertation on craniology in Greenwell's *British Papers* (1877). See Life prefixed to his *Scientific Papers and Addresses* (ed. Turner and Tylor, 2 vols. 1884).

Rolliad, the name, derived from Lord Rolle (1750-1842), a staunch supporter of Pitt, for a series of Whig satires by George Ellis and others, directed mainly against Pitt and Dundas.

Rollin, CHARLES, born at Paris, January 30, 1661, studied at the Collège du Plessis, and became professor there, next at Paris, and was chosen rector of the university of Paris in 1694. In 1699 he was appointed condoctor to the principal of the Collège de Beauvais, but was ejected from this situation twelve years later owing to his Jansenistic sympathies. He was re-elected rector of the university in 1720, and died September 14, 1741. His *Traité des Etudes* (4 vols. 1726-31) has been pronounced by Voltaire 'a monument of good sense and taste'; his *Histoire Ancienne* (13 vols. 1730-38), long popular and much translated, is feeble in its philosophy, jejune in its criticism, and often inaccurate in its facts. Yet it has opened the study of ancient history to many men since the young prince Frederick the Great. His *Histoire Romaine* (16 vols. 1738-48) was a much inferior work, long deservedly forgotten. See a book by Férty (1902).

Rollin, LEDRU. See LEDRU-ROLLIN.

Rollo. See NORTHMEN, NORMANDY.

Rolls, MASTER OF THE, was formerly the chief of the twelve Masters in Chancery, entrusted with the care of grants passed under the great seal, and of all the records of the Chancery; he also sat on the equity side of the court as an independent though subordinate judge; doubts having been raised as to his jurisdiction, his powers were confirmed by act of parliament in 1730. The official residence of the Master of the Rolls in Chancery Lane, with the chapel, &c. thereto attached, form the Liberty of the Rolls. The Master of the Rolls was formerly permitted to sit in the House of Commons, and this usage was defended in a well-

The Common Roller (*Coracias garrula*).

and Shetlands, one has been found as far west as St Kilda, and about half a dozen have been recorded from Ireland. It is a struggler to northern Europe; in central Europe it is common; in

known speech by Macanlay. By the Judicature Act of 1873 the Masters of the Rolls was excluded from the House of Commons; he has since been transferred, by an act passed in 1881, to the Court of Appeal, but he continues to perform administrative duties as head of the Record Office. For the Rolls Series, see RECORDS.

Romagna, formerly the name of a region of Italy, forming the northern portion of the states of the Church (q.v.), in eastern Emilia. From the middle of the 8th century, when the Frankish king Pepin gave the Exarchate of Ravenna to the Roman Church, the Romagna witnessed struggles immeasurable between the papal and the temporal authorities of the region. In 1861 the *legations* of Bologna, Ravenna, Ferrara, and Forlì, of which the Romagna then consisted, became provinces of the kingdom of Italy.

Romaic, a term for the popular Greek dialect developed before the fall of the Byzantine empire, essentially similar to the modern Greek tongue as now spoken. The first who wrote in this popular tongue is believed to have been a monk Prodomius in the 12th century. Those who cling to the old Attic, which still maintained an artificial existence, called themselves *Hellenes*; the party of the popular speech were called *Rhomaioi*, from *Nea Rhomē* ('new Rome'), the new name for the capital of the eastern empire. See GREECE.

Romaine, WILLIAM, evangelical divine, was born at Hartlepool, 25th September 1714, and was educated at Hertford College and Christ Church, Oxford. He held various curacies and lectureships in London. In 1764 he was chosen rector of St Andrew Wardrobe and St Ann's, Blackfriars, and though the election was disputed it was confirmed by the Court of Chancery in 1766, and he held the living till his death, 26th July 1795. Romaine was a bulwark of Evangelicalism in his day, though himself infected with the taint of Hutchinsonianism. He assailed, not without credit, Warburton's *Divine Legation of Moses*; published commentaries, many sermons, and three books of edification that enjoyed for three generations a remarkable popularity: *The Life of Faith* (1763), *The Walk of Faith* (1771), and *The Triumph of Faith* (1794). There is a complete edition of his works, with a Life by the Hon. and Rev. W. B. Cadogan (8 vols. 1796).

Roman, a town in Moldavia, Rumania, near the junction of the Moldava and Sereth, 36 miles SW of Jassy. It is the seat of a Greek bishop, with a cathedral (1541), and has beet-sugar factories. Pop. 18,000 (including many Jews).

Roman Architecture. The foundation of Rome falls in the same century as the earliest Greek settlements of Southern Italy and Sicily; but her art and architecture were influenced not by them, but by the Etruscans, the origins and affinities of whom, as well as the date of their arrival in Italy, are as yet unknown. It was to the Tarquins that the Cloaca Maxima and the temple of Jupiter Capitolinus were due; and while some of the branches of the former are preserved, providing examples of the oldest Roman arches we have¹ (see ROME, p. 762), we can form an idea of the aspect of the latter from discoveries in Etruria, and especially from the discovery at Veii of terra-cotta statues of the same date, and probably by the same school of artists.² This, then, and the other early temples of Rome, were in the Etruscan, or rather Italic, style, raised on a podium, with columns in

front only, and often with three cellæ; the superstructure was partly of stone, partly of wood, and the decoration in painted terra-cotta.³ After this, however, there is a long gap; and the next buildings we get in Rome and its neighbourhood are aqueducts, bridges, and comparatively small temples (though at Tivoli and Palestrina they are associated with huge substruction walls and terraces going up the hillside), not at all influenced by what went before, but derived from Hellenistic models of the beginning of the 2d century B.C., in which examples of the Doric, Ionic, and Corinthian orders are to be found. One of the finest, the so-called temple of Fortuna Virilis (probably Mater Matuta) in the Forum Boarium in Rome, really belongs to the time of Julius Caesar, and buildings of similar style are to be found in the early Augustan age—some of them, like it, constructed of volcanic tufa (or else peperino) and travertine (a hard limestone), which materials were at that period covered (and this must never be forgotten) with a heavy coating of stucco, in which the finer mouldings were expressed; while others were built in marble (such as the temples of Saturn and Julius Caesar, and the Regia).

The use of the arcade in elevation (i.e. the engaged column combined with the arch) is first found in the Tabularium (78 B.C.), where there is an arcade, with Doric half columns attached, carrying an entablature (a characteristic combination in Roman architecture), above which was a Corinthian colonnade. Such a building postulates the knowledge of the potentialities of concrete, and especially of concrete vaulting. A great advance in their use was made when, in the time of Augustus, kiln-baked bricks (fragments of roof tiles were at first used, bricks coming in only under Claudius) began to be used instead of, or in combination with, small pieces of stone as facing, and this rendered possible the construction of enormous concrete walls. A further advance was the introduction of ribs of tiles under Domitian; they were first used under Hadrian in intersecting vaults, which are the prototype of all later cross-vaulting. (They are not used in the Pantheon, where there is a series of arches in the lower part of the dome, and pumice-stone is largely used in the skin to decrease the weight.) This diminished the amount of scaffolding required, as well as the weight of the vault itself, and the great domed constructions of the 3d and following centuries, one of the most important of which, in the history of construction, is

Fig. 1.—Plan of the so-called Temple of Minerva Medica at Rome.

the so-called Temple of Minerva Medica (really a nymphaeum—fig. 1), owe their origin to this invention, and from them spring the Christian circular

¹ In Etruria proper we can point to no line arch before the 8d century B.C., nor indeed anywhere else in Italy.

² Pliny tells us that the statue of Jupiter was executed by one Vulca of Veii, and was in painted terra-cotta (*Nat. Hist.* xxv. 157).

³ A very good idea of such temples can be had from the reconstruction by Bradshaw in *Papers of the British School at Rome*, vii. pl. 1.

and polygonal churches and baptisteries. The planning of such a building as the Baths of Caracalla is not less remarkable than the architecture of the superstructure. But, from the point of view of construction and staties, it is the Baths of Diocletian (with which may be taken the Basilica of Maxentius) which sum up the principles attained by the architects of imperial Rome, and point the way forward to succeeding ages.

When we come to decoration, we find that the Romans had developed the three Greek orders on their own lines. The column of the Doric order, which is Hellenistic in origin, is slenderer than its Greek prototype, and generally has a base, while the capital is more developed in later examples. The Tuscan, a simplified form of the Doric, with inflated shaft, often rests upon a pedestal, as in the lower arcade of the Colosseum (fig. 2). The Ionic

Fig. 2.—Doric Arcade.

and Corinthian were less refined than in Greek architecture, and the former, in some examples, had the volutes turned out angularwise, so as to present a similar face in each direction; while the latter was far more freely used, and was thus more fully developed. In fact, most of the finest buildings in Rome (the temples of Castor and Mars Ultor, and the Pantheon, for example; see *ROME*, p. 764), and many in the provinces (e.g. the *Maison Carrée* at Nîmes), are in this style. The most characteristic type is perhaps the pseudo-peripteral, with half-columns instead of side colonnades; though, where the space was sufficient, peripteral temples occur (the best example is perhaps the temple of Castor). The derivation of the circular temple probably goes back as far as the circular hut of primitive days. The Composite, a combination of these two orders, was invented by the Romans, and largely used on triumphal arcades. The mouldings became gradually more elaborate, and we get a kind of imperial baroque architecture, well exemplified at Baalbek. The walls were enriched by facing in slabs of marble or in plaster decorated with painting, while for the vaults stucco, white or coloured, was used—in large buildings often with coffering. The pavements were of marble or of mosaic; the latter came more slowly into use on walls, while in domes it is not found before the 2d century A.D., and even then is rare. The use of the arch springing direct from the column, a feature of such great importance for Christian architecture, is a natural development from the use of the arch springing from a massive stone pillar, and is found on a small scale in houses in Pompeii. One of its best-known exemplifications is in the palace of Diocletian at Spalato (fig. 3), where the architrave is bent round the arch; but the cornice is still continued horizontally above it, and this

remains characteristic of the architecture of the Christian basilicas.

The prototype of these buildings had already been fully evolved in Rome in pagan times, as is

Fig. 3. - Central Courtyard of the Palace of Diocletian, Spalato.

shown by the discovery, close to the Porta Maggiore, of the famous underground basilica of the 1st century A.D.¹ Halls with or without apses, the larger of which were divided by columns into nave and aisles, were in fact common in the Pagan period, and were used for such various purposes that the Christian basilica can hardly be said to be derived from any one type. There are, further, cases in which the nave was certainly raised above the aisles and roofed separately from it (e.g. the Basilica Emilia in the Forum in Rome); and it must be remembered that the apse is so little an essential part of the basilica that many pagan (and a few Christian) basilicas are without it. Nor is either the atrium nor the transept an integral or necessary part of it. What distinguished the Christian basilicas from their predecessors were rather the differences due to their new purpose, which led to their decoration with mosaics and paintings of a new character, though having their roots in classical art. Wilpert's splendidly illustrated work, *Die Römischen Mosaiken und Malereien* (Freiburg im Breisgau, 1917), may be referred to for Rome itself; cf. also the article RAVENNA. Such a characteristic feature as the open wooden roof, so common in mediæval churches, was probably concealed at first by a flat ceiling in painted plaster, as at Aquileia. But it was with the rise of Romanesque Architecture (q.v.) that the transition from the classical to the mediæval period began.

For the various monuments of Roman architecture, see the articles AMPHITHEATRE, AQUEDUCT, BASILICA, BATHS, OSTIA, POMPEII (these last two for domestic architecture), ROME, SPALATO.

Roman Catholic Church. practically the 'church militant' as defined by Cardinal Bellarmine: 'An assembly of men united by the profession of the same Christian faith, and by the

¹ Strong and Jolliffe in *Journal of Hellenic Studies*, xlv, (1924) 65 sqq.

communion of the same sacraments, under the rule of legitimate pastors, and especially of the one vicar of Christ on earth, the Roman pontiff.' It is evident that this is really a definition of the Roman Catholic Church. The truth is that the Roman Catholic Church claims exclusive right to the title of Church of Christ on earth, and declares that 'outside of her fold there is no salvation.' This claim of the Church of Rome to be the exclusive means of salvation has been much misunderstood, and calls for some words of explanation. As we intend to remove a misconception, we explain first what the claim does not mean. It does not mean that none but Roman Catholics are in the way of salvation. This is sufficiently clear from the Encyclical letters ('Quanto conficiamur') of Pope Pius IX., dated August 10, 1863. 'It is well known,' writes His Holiness, 'that those who labour under an invincible ignorance concerning our most holy religion, and who at the same time sedulously observing the natural law and the precepts thereof, which are inscribed by God on the hearts of all, are ready to obey God, can, the virtue of divine light and grace working within them, attain to eternal life.' It is not then the teaching of the Roman Church that none but Roman Catholics are saved. The sense of the axiom 'outside the Church of Rome there is no salvation,' as understood by Roman Catholic theologians, is that, whereas Christ came on earth to establish a church which was to be the divinely appointed means for the salvation of all men, the Roman Catholic Church is that church. Further light may be cast on the sense of this axiom by considering the distinction made by Roman Catholic theologians between the body of the church and the soul of the church. By the body of the church they understand the church considered as a visible and external society. By the soul of the church they understand the supernatural life of the members of the church—that is to say, sanctifying grace. Whoever, then, is in the state of grace belongs to the soul of the church. Whoever is not in the state of grace, even though he belong to the visible and external organisation or body of the church, does not belong to the soul of the church. Now the axiom 'outside the church there is no salvation' has reference primarily to the soul of the church. Thus, then, according to Roman Catholic doctrine, the non-Catholic who dies in the state of grace is saved. The Catholic who dies out of the state of grace is lost.

In the symbol commonly known as the Nicene Creed, faith is expressed in 'one, holy, Catholic, and Apostolic Church.' Christian antiquity then regarded unity, sanctity, catholicity, and apostolicity as properties of the true church. The Church of Rome claims to possess these properties, and to possess them manifestly, and in consequence claims to be clearly recognisable as the true church of Christ.—The Church of Rome claims to be *one*, with the completest and most perfect unity, with unity of doctrine, unity of liturgy, and unity of government. (1) With unity of doctrine. Roman Catholics all the world over have precisely the same faith: the learned, indeed, may have a larger acquaintance with the doctrines of faith than the illiterate; but there is nothing believed by the most learned theologian which is not believed, at least implicitly, by the most simple member of the faithful. Every Roman Catholic says, 'I believe whatever the holy Catholic Church proposes for my belief.' (2) With unity of liturgy. In every part of the world the Roman Catholic Church offers the same unbloody sacrifice of the mass, everywhere administers the same sacraments, everywhere observes the same great festival days, &c. (3) With unity of government. Roman

Catholics, whether living under monarchical or republican governments, whether united to each other or divided from each other by their various national interests, are everywhere in subjection to their pastors and bishops, and above all to the Holy See. Indeed, it has perhaps never been denied that with respect to unity the Roman Catholic Church excels all other churches.—The Roman Catholic Church claims to possess visibly the second property of the true church—viz. *sanctity*. She claims to be holy (1) by reason of the holy doctrines which she teaches. Thus, she insists upon the great truth of moral responsibility. She declares that, though man's freedom of will was impaired by the Fall, it was not destroyed; that freedom of will remains, and that no adult can be saved without the due exercise of it. She proclaims that 'faith without works is dead.' She calls upon her children to confront their evil passions with the weapons of fasting and mortification in their hands; holds in high honour the 'life of counsels,' the life of voluntary poverty, chastity, and obedience; and declares that such was the life of the Lord and of the precursor of the Lord. (2) By reason of the means of holiness which she provides. Prominent amongst these a Roman Catholic would place the sacrament of penance. (3) By reason of the fruit of holiness which she produces. Professing that she has existed from the first, the Roman Catholic Church claims as her own all the saints of past times. She declares that her power of producing saints is strong to this day, and points to a St Francis Xavier, a St Charles Borromeo, a St Philip Neri, a St Francis de Sales, a St Vincent de Paul, and many other saints of more recent times. And whoever is acquainted with the rigorous inquiry which precedes the process of canonisation, whatever he may think of the faith of those canonised by Rome, will admit that the saints of the Roman Church were men of even heroic virtue.—The Roman Catholic Church claims to possess visibly the third property of the true church—viz. *catholicity*. She claims to be Catholic *de jure*, inasmuch as she was commissioned to 'teach all nations'; and also *de facto*, and this in three ways. (1) With respect to persons. This means that Roman Catholics constitute by far the most numerous body of Christians. (2) With respect to place. This means that the Roman Catholic religion is more or less diffused wherever Christianity prevails. (3) With respect to time. This means that she has existed visibly since the days of the apostles, and that she will exist visibly till the end. The claim of continued existence from the first really merges into the claim of apostolicity, which we shall next explain. Her belief in her continuance of existence till the end she bases on Christ's promise of constant assistance, which she declares was made to herself.—Finally, the Church of Rome claims to possess visibly the fourth property of the true church—*apostolicity*. She claims to be apostolic (1) as founded by Christ through the apostles, and because her pastors descend from the apostles by a succession which has never been broken. Under this head we may remark that, while many Protestant writers have denied that St Peter the apostle ever resided in Rome, on the other hand many well-known Protestant authorities, such as Barrow, Cave, Chamier, Vossius, Baratier, Bishop Pearson, and Whiston, have freely conceded this to the Catholics. Whiston states that the fact of St Peter's residence at Rome 'is so clear in Christian antiquity that it is a shame for any Protestant to confess that any Protestant ever denied it.' Bishop Pearson declares that 'it is wonderful that those can be found who deny that Peter ever was at

Rome.' Baratier is still more emphatic: 'All the ancients,' he writes, 'and the great majority of the moderns have undertaken to derive the succession of the bishops of Rome from the apostle Peter. So great in this matter has been the agreement of all that in truth it ought to be deemed a miracle that certain persons born in our day have presumed to deny a fact so manifest.' Besides claiming connection with the apostles, by a line of pastors descending from them in uninterrupted succession, the Church of Rome claims to be apostolical (2) by reason of her doctrines. She denies that she has ever surrendered any doctrine taught by the apostles, and she denies that she has ever professed any doctrine which is not contained in divine apostolical tradition. Here it must be remembered that, while the Church of Rome accepts the Word of God alone and exclusively as the Rule of Faith, besides the Sacred Scriptures or written Word of God it admits an unwritten Word of God, which possesses an authority equal to that of the written Word. By the unwritten Word of God Roman Catholics understand a body of truths delivered by Christ to the apostles, and by the apostles to their successors, which were not in the first instance committed to writing. It is certainly worthy of note that Christ did not write, but preach; that he did not command his apostles to write, but to preach; that only five out of the twelve apostles—reckoning St Matthias in the place of Judas—are recorded to have written anything at all; that three out of these five—St Peter, St James, and St Jude—have left us nothing more than brief epistles, written under particular circumstances, and for special reasons; that more than half of the New Testament was written by inspired men who were not among the apostles to whom the commission was addressed by our Saviour. The church is the depository, guardian, and living and infallible interpreter of both the written and the unwritten Word of God. It may be remarked, in passing, that there would seem to be some analogy between the Roman Catholic rule of faith and the civil constitution of England. According to Judge Blackstone's Commentary, the municipal laws of England are divided into *lex non scripta*, the unwritten or common law, and the *lex scripta*, or statute law; and the common law is the 'first ground and chief corner stone of the laws of England.' If the question arises as to how these customs or maxims are to be known, and by whom their validity is to be determined, Blackstone decides that the question must be settled by the judges in the several courts of justice, for these judges are 'the depositaries of the law, the living oracles, who must decide in all cases of doubt.'

The Church of Rome teaches that no addition has ever been made to the deposit of faith left by the apostles to the church, and that no objective increase of revelation is to be expected. She does not deny that divine revelations have been made to individuals since the days of the apostles, but she holds that such revelations do not increase the deposit of Christian revelation, and do not constitute an article of Catholic faith to be professed by all the faithful. The faithful are not bound to accept revelations made to private persons, even though the church should express approval of these revelations; for it is understood that the church does not intend by her approval to guarantee their genuineness. The approval of the church amounts to no more than a declaration that there is nothing in the supposed revelations at variance with sound faith and morality. But though the entire deposit of faith was received by the church from the apostles, it does not follow that all the truths contained in this deposit were revealed *explicitly*, and have been at all times

explicitly taught by the church. There has, indeed, never been any difference with respect to the *formal* object, as it is called, or motive of faith. Whatever truth has been believed has always been accepted on the authority of God who revealed it. But with respect to the *material* object of faith—i.e. the truths of revelation—there has been this difference, that, while some have been from the first explicitly believed, others were at one time believed implicitly only. The distinct proposition and promulgation of these latter doctrines belongs to the *magisterium*, or teaching office, which the church exercises under the guidance of the Holy Spirit.

The church fulfils this teaching office in many ways: (1) By indicating in detail the various truths contained in some complex article of explicit faith. Thus, it was always expressly believed by the church that our Saviour was a true and perfect man. But if our Saviour was truly man it follows that He possessed a human body, a rational soul, a human will, and a human energy. And these various consequences the church distinctly proposed for explicit belief, on the emergence of the Gnostic, Apollinarian, Monothelite, and other heresies at variance with these consequences. Or, to take an instance from Roman Catholic theology, the plenitude of the primacy of the Bishop of Rome has always been a principle of faith explicitly believed. But, as occasions and circumstances required, the church has proposed for explicit faith one or other of the prerogatives involved in this primacy. (2) By enunciating in particular truths already comprehended in some universal proposition of explicit faith. Thus, while the church had already taught that grace was necessary for all salutary actions and states, on occasion of the Sempiternal heresy it distinctly decreed that grace was necessary for entrance into the way of salvation and for perseverance in the same. (3) By proposing distinctly and articulately what was already believed, though with less distinctness. Thus, according to Roman Catholics, it has always been the belief of the church that it was due to the honour of the Son of God that His mother should be free from the least stain of sin. The proclamation, then, in recent years of the doctrine of the Immaculate Conception was no more than the distinct and articulate declaration of a truth which had been an object of implicit belief from the first. (4) By expressly declaring some truths which had been already indicated by the practice of the church. Thus, the church, by not rebaptising those converted to her fold from heresy, had practically manifested her belief in the validity of baptism conferred by heretics; but when the validity of heretical baptism was impugned she expressly declared that where the proper matter, form, and intention were employed such baptism was valid. Thus, then, according to the Roman Catholic teaching, there may be truths objectively contained in the deposit of revelation, or the remote rule of faith, which have not been always clearly proposed and promulgated by the proximate rule of faith—i.e. the *magisterium* of the church. Until they are thus proposed and promulgated they may be called in question without loss of faith; for the unity of faith is maintained so long as there is due subjection to the *magisterium* of the church. In the history of many doctrines we may distinguish three distinct phases: (1) In the first instance, they are implicitly contained in revelation indeed, but not yet proposed by the church; and by the faithful they are not explicitly believed, neither are they called in question. (2) Then arises a controversy concerning these doctrines; some are for accepting, others for rejecting them. (3) Finally, the church,

either by solemn judgment or by her common teaching, declares that these doctrines belong to the deposit of revelation; and thenceforward they are an object of explicit faith.

For the teaching of the Roman Catholic Church concerning the Holy See we must refer our readers to the articles POPE, INFALLIBILITY, &c. We may, however, mention here that the very name Roman Catholic is intended as an expression of the belief that there can be no true Catholicity without union with Rome. Roman Catholics assert that there can be no catholicity without unity; and they contend that the See of Rome has always been regarded as the source of unity, and that communion with Rome was regarded by the early church as the ultimate proof of orthodoxy. In support of this contention they quote many striking declarations of the Fathers and of the early councils. The name 'Roman Catholic' is not new. Cardinal Newman, writing of the 5th and 6th centuries, says: 'It is more than remarkable that Catholics of this period were denoted by the additional title of "Romans." Nor was this association of Catholicism with the See of Rome an introduction of that age' (*Essay on Development*, chap. c.).

The hierarchy of the Roman Catholic Church consists of the sovereign pontiff, who is assisted by the Sacred College of Cardinals, and by several sacred congregations, or permanent ecclesiastical committees; of the patriarchs, archbishops, and bishops; of the apostolic delegates, vicars, and prefects; and of certain abbots and prelates. The cardinals, who are the advisers and assistants of the sovereign pontiff, constitute the supreme council or senate of the church; and on the death of the pontiff they elect his successor. The College of Cardinals when complete consists of 70 members: 6 cardinal bishops, whose dioceses are the 6 'Suburban Sees' of Ostia, Velletri, Porto and Santa Rufina, Albano, Frascati, Palestrina, and Sabina, 50 cardinal priests, and 14 cardinal deacons. The sacred congregations carry on the central administration of the Roman Catholic Church.

(1) The Congregation of the Holy Office deals with heresy, indulgences, mixed marriages, and (since the decision in 1917 of the Congregation of the Index) condemnation of writings prejudicial to faith or morality (see INDEX, INQUISITION); (2) The Consistorial Congregation prepares matter for Consistories, and deals with matters relating to dioceses and bishops, &c.; (3) The Congregation of Sacramental Discipline deals with matrimonial dispensations, and other matters relating to marriage, and the sacraments generally; (4) The Congregation of the Council, originally for the interpretation and execution of the decrees of the Council of Trent, deals with observance of precepts of the Church, with secular clergy, ecclesiastical property, and much else; (5) The Congregation for the Affairs of Religions, with questions between members of religious orders or between them and bishops; (6) The Congregation of Propaganda, for the propagation of the faith and the government of the church in non-Catholic countries; (7) The Congregation for the Eastern Church with jurisdiction over persons and things pertaining to the Oriental Rites; (8) The Congregation of Sacred Rites, for the decision of all questions relative to the liturgy, rites, and ceremonies, and for the conduct of the processes of the beatification and canonisation of saints; (9) The Congregation of the Ceremonial for papal ceremonies, ceremonial of cardinals, &c.; (10) The Congregation of Extraordinary Ecclesiastical Affairs for consideration of matters specially submitted to it by the pope; (11) The Congregation of Seminaries and Universities of Studies, for supervision of courses, con-

ferring of degrees. The jurisdiction of the congregations does not cease on the death of the sovereign pontiff; nevertheless all important business is suspended during the vacancy of the Holy See.

There are 10 patriarchates, with 14 patriarchal sees—8 of the Latin rite, and 6 of Oriental rite. The greater or more ancient patriarchates are those of Alexandria, *Latin* and *Coptic*, Antioch, with 4 patriarchal sees, *Latin*, *Maronite*, *Melchite*, and *Syriac*; Constantinople, *Latin*; and Jerusalem, *Latin*. The less are those of Babylon, *Chaldeic*; Cilicia, *Armenian*; East Indies, *Latin*; Lisbon, *Latin*; Venice, *Latin*; and West Indies, *Latin*. There are in the communion of Rome, besides the 14 patriarchal sees, about 1000 archiepiscopal and episcopal *residential* sees. Besides the metropolitans and bishops of these residential sees, there are some 600 archbishops and bishops of *titular* sees. Titular sees, or, as they were styled till 1882, sees *in partibus infidelium* i.e. sees which in ancient times existed in those eastern regions which have now lost the faith and fallen into barbarism—are, for the most part, assigned to archbishops and bishops who are appointed to apostolic delegations, to vicariates-apostolic, to prefectures-apostolic, or to the office of conditor, auxiliary, or administrator of a diocese. Delegates-apostolic and vicars-apostolic enjoy episcopal jurisdiction, and exercise episcopal powers, in countries where a hierarchy proper has never been established, or having once existed has been suppressed. When the ancient hierarchy of England came to an end in 1555 with the death of Thomas Goldwell, Bishop of St Asaph, the English Catholics were at first placed under the jurisdiction of archpriests or prefects-apostolic. But in the year 1623 Pope Gregory XV. appointed a vicar-apostolic with jurisdiction over all the Catholics of England. About sixty years later, in 1688, Pope Innocent XI. created four districts or vicariates, the London, Midland, Northern, and Western, appointing to each district its own vicar-apostolic. In 1840 Pope Gregory XVI. created eight districts or vicariates, the London, Western, Eastern, Central, Welsh, Lancashire, Yorkshire, and Northern, each district having, of course, its own vicar-apostolic. In 1850 Pope Pius IX. re-established the Roman Catholic hierarchy in England. The vicars apostolic were all bishops of titular sees. Thus, Cardinal Wiseman, who before the restoration of the hierarchy was vicar-apostolic for the London district, was entitled while vicar-apostolic Bishop of Melipotamus. Prefects-apostolic are as a rule not bishops, but simple priests, who receive from the Holy See authority to exercise quasi-episcopal jurisdiction in missionary countries.

As is well known, the Latin rite prevails with few exceptions in the West, and also in some regions of the East; nevertheless various other rites are also followed within the communion of Rome. These are (1) the Greek rite, of which there are the following forms. (a) The Greco-Romanian. There are 3 bishops and 1 archbishop of this rite, whose sees are situated in Rumania. The language of the liturgy is Rumanian, excepting in the parish of Scasiu, in the diocese of Lugos, where the language employed is ancient Slav. (b) The Greco-Ruthenian. There are 8 bishops and 1 archbishop of this rite, with sees in Galicia and Poland proper and elsewhere. The liturgical language is ancient Slav. (c) The Greco-Bulgarian. Of this rite there are 2 bishops, vicars apostolic, for Macedonia and Thrace. The liturgical language is ancient Slav. (d) The Greco-Melchite. Of this rite is the Melchite patriarch of Antioch, with a number of archbishops and bishops, whose sees are situated in Syria. The liturgical language is Arabic. (e) The pure Greek rite, also in communion with Rome, is under Latin delegates-apostolic at Athens and

Constantinople, with a bishop in Hungary and one in Italy. (2) The Syriac rite, of which there are the following forms. (a) The pure Syriac. Of this rite is the Syriac patriarch of Antioch, with 4 archbishops and 4 bishops, whose sees are situated in Syria, Iraq, and Turkey. The liturgical language is ancient Syriac. (b) The Syro-Chaldaic. Of this rite is the patriarchate of Babylon, with 2 archiepiscopal and 10 episcopal sees situated in Kurdistan, Turkish Armenia, Mesopotamia, and Persia. The liturgical language is ancient Chaldaic. (c) The Syro-Maronite. Of this rite is the Maronite patriarch of Antioch, with 7 archbishops and 2 bishops, whose sees are situated in Syria, Turkey, and Cyprus. The liturgical language is ancient Syriac. (d) The Syro-Malabaric. There is an archbishop at Ernakulam, with 3 bishops in Southern India. The liturgical language is Syro-Malabaric. (3) The Armenian rite. To this rite belong the Armenian patriarchate of Cilicia, the archiepiscopal see of Lemberg, and many other archiepiscopal and episcopal sees situated in Turkey, Syria, Egypt, and Persia. The language of the liturgy is ancient Armenian. (4) The Coptic rite. Of this rite there are two forms: (a) the form followed under the Coptic patriarchate of Alexandria, where Coptic or ancient Egyptian is the language of the liturgy; (b) the form observed in the vicariate apostolic in Abyssinia, where the liturgical language is ancient Ethiopic or Ge'ez.

The Catholic population of the world is estimated at 317½ millions of the Latin rite and 7 millions of other rites. Of these 15½ millions are in the British Empire, and nearly 28 millions in the United States and its possessions (including 8 millions in the Philippine Islands).

Roman Catholic Emancipation. See CATHOLIC EMANCIPATION.

Romance Languages, a general name for these modern languages that are the immediate descendants of the language of ancient Rome. In those parts of the empire in which the Roman dominion and civil institutions had been most

completely established the native languages were speedily and completely supplanted by that of the conquerors—Latin. This was the case in Italy itself, in the Spanish peninsula, in Gaul or France, including parts of Switzerland, and in Dacia. When the Roman empire was broken up by the irruptions of the northern nations (in the 5th and 6th centuries) the intruding tribes stood to the Romanised inhabitants in the relation of a ruling caste to a subject population. The dominant Germans continued, where established, for several centuries to use their native tongue among themselves; but from the first they seem to have acknowledged the supremacy of Latin for civil and ecclesiastical purposes, and at last the language of the rulers was merged in that of their subjects; not, however, without leaving decided traces of the struggle—traces chiefly visible in the intrusion of numerous German words, and in the mutilation of the grammatical forms or inflections of ancient Latin, and the substitution thereof of prepositions and auxiliary verbs. It is also to be borne in mind that the language which underwent this change was not the classical Latin of literature, but a popular Roman language (*lingua Romana rustica*) which had been used by the side of the classical, and differed from it—not to the extent of being radically and grammatically another tongue—but chiefly by slovenly pronunciation, the neglect or misuse of grammatical forms, and the use of 'low' and unusual words and idioms. As distinguished from the old *lingua Latina*, the language of the church, the school, and the law, this newly formed language of ordinary intercourse, in its various dialects, was known from about the 8th century as the *lingua Romana*; and from this name, through the adverb *romance*, came the term Romance, applied both to the language and to the popular poetry written in it, more especially to the dialect and poems of the troubadours. The Romance languages recognised by Diez are six—Italian, Spanish, Portuguese, Provençal, French, and Rumanian. Ascoli and newer investigators treat the Rumanian of the Girsons as a seventh sister-tongue; and each of these has more or less numerous dialects.

It is beyond doubt that the several daughters of the mother Latin had their characteristic differences from the very first, as, indeed, was inevitable. The original Latin spoken in the several provinces of the Roman empire must have had very different degrees of purity, and the corruptions in one region must have differed from those in another according to the nature of the superadded tongues. To these differences in the fundamental Latin must be added those of the superadded German element, consisting chiefly in the variety of dialects spoken by the invading nations and the different proportions of the conquering population to the conquered. French, as was to be expected, is richer in German words than any other member of the family. Italian is next to French in this respect, but on the whole is nearest to the mother Latin. Spanish and Portuguese have considerable Arabic elements; and Rumanian was much modified by Slavonic. The Romance tongues further differ from the common parent in simplifying or dropping the inflections of nouns, substituting for these the use of prepositions, and simplifying the verbal forms by a free use of auxiliary verbs. The Romance tongues and their literatures are treated in the articles on Italy, Spain, Portugal, Provençal, France, Rumania, Rumanisch.

See Cornwell Lewis, *On the Origin and Formation of the Romance Languages* (2d ed. 1862); Diez, *Grammatik der romanischen Sprachen* (1836-44, and later editions), and his dictionary, the great *Wörterbuch* (1853, and later editions; Eng. trans. 1864); Paul Meyer, *Rapport sur*

le Progrès de la Philologie Romane (1874); works on Romance philology by Korting; Gröber, *Grundriss der romanischen Philologie* (1888-1902; new ed. 1906); Meyer-Lübke, *Grammatik der romanischen Sprachen* (1890-1902), *Einführung in die rom. Sprachwissenschaft* (1809), and in Hinneberg's *Kultur d. Gegenwart* (vol. i. 1909); and the periodicals *Romanische Studien* (1871 et seq.), *Romania* (1873 et seq.), *Romanische Forschungen* (1883 et seq.).

Romances. Romance has long since lost its original signification in every country except Spain, where it is still occasionally used in speaking of the vernacular, as it was in the middle ages when Latin was the language of the lettered classes and of documents and writings of all kinds. But even there its commoner application is, as elsewhere, not to a language, but to a form of composition. In English it has been almost invariably applied to a certain sort of prose fiction, and, in a secondary sense, to the style and tone prevailing therein. By 'the romances,' using the term specifically, we generally mean the prose fictions which, as reading became a more common accomplishment, took the place of the lays and *Chansons de geste* (q.v.) of the minstrels and trouvères, and were in their turn replaced by the novel. Of these the most important in every way are the so-called romances of chivalry, which may be considered the legitimate descendants of the *chansons de geste*. The chivalry romances divide naturally into three families or groups: the British (which, perhaps, would be more scientifically described as the Armorican or the Anglo-Norman), the French, and the Spanish; the first having for its centre the legend of Arthur and the Round Table; the second formed round the legend of Charlemagne and the Twelve Peers; and the third consisting mainly of *Amadis* of Gaul followed by a long series of sequels and imitations of one kind or another. In strict chronological order the Charlemagne cycle should stand first, for the Charlemagne legend was apparently of an earlier formation than the Arthurian; but on the other hand the materials out of which the Arthur legend shaped itself must of course have been the older, and the prose romances which either grew out of it or were grafted upon it are for the most part of an earlier date than those belonging to the Charlemagne story.

The first appearance of Arthur is in the history of Nennius, where he is presented in a quasi-historical shape, simply as the chosen leader of the Britons in twelve successful battles fought with the Saxons; but it is in the *Historia Regum Britannie* of Geoffrey of Monmouth (1140) that he first appears as the hero of a connected story. Geoffrey, in fact, may be fairly claimed as the founder of the Arthurian legend. Whatever his materials may have been or whatever the source from which he obtained them, he contrived to give them 'un caractère chevaleresque et courtois,' to use the words of M. Gaston Paris, which was altogether foreign to them when they came to his hands, and thus succeeded in presenting a picture of Arthur and his court which at once proved acceptable to the age in which he lived. It is this character, impressed upon the Arthur legend by Geoffrey, that led Cervantes to regard it as the fountain-head of chivalry and chivalry romance, as he does in *Don Quixote* (part I, chap. xiii.). The story, however, as Geoffrey left it, is little more than the foundation of the structure raised by his successors a century later. Whether we accept in its entirety or in part only his account of the 'very ancient book' from Brittany which he professed to have translated, or hold that his authorities were simply Nennius, Welsh traditions, and Breton lays and tales, it is clear that his sources of information conveyed no hint of the Round Table or of the

Grail, to say nothing of Lancelot and other personages who have come down to us as part and parcel of the Arthurian story. The first reference to the Round Table is in the *Brut* of Wace (1155), which is in fact an amplified metrical version of Geoffrey's history, and from the words used—'Fist Artas la rounde table, dont Breton dient mainte fable'—we are left to suppose that it was through Breton tradition that it found its way into the story. By some it has been conjectured that in the Round Table we have only an imitation of the Peers of the Charlemagne legend, but in truth the two institutions represented two totally distinct ideas. The peers were simply a fraternity, 'xii. compaignons,' as the Chanson de Roland calls them, bound together by mutual affection alone, with no ulterior aim or object, and entirely uninfluenced by the sovereign. The Round Table, on the other hand, was a knightly fellowship in which the bond of union was the pursuit of chivalrous adventures and 'deeds of worship,' of which the king was the head, and by which he was 'upborne' and the quiet and rest of his realm insured. The distinction deserves notice, for it is characteristic of the difference between the two legends and the romances that represent them. The Arthurian stories were knightly and courtly, their authors were courtiers, sometimes knights; if we may trust the statements of early editors, they were written to order at the instance of magnates, among whom Henry II. and Henry III. of England are named, and at any rate were obviously addressed to what would now be called the aristocratic section of society. With the Carolingian it was very different; the *chansons de geste* from which they were derived were made for and sung to no one class in particular, and it is manifest that the selection for translation into prose was always governed by considerations of popular interest. Hence the phenomenon noticed by more than one observer, that the Arthurian stories have never become in the strict sense of the word popular in any age or country, while the Carolingian have enjoyed a wide-spread popularity, and in some instances continued to hold their own as popular stories down to the present day. Mr J. A. Symonds observes that in Italy the Arthurian stories, though relished by the cultured classes, never took the fancy of the people at large in the same way as the Carolingian; and in Spain the romances and ballads that treat of Arthur are few and meagre, while the Charlemagne literature is extensive and rich, and the *History of Charlemagne and the Twelve Peers* is still a current chap-book in high request. A more obscure question is how the Holy Grail came to be linked to the Arthurian story. There can be no doubt that Celtic tradition and mythology present sufficient analogies to justify a theory that the idea of the Grail is a purely Celtic one which may be traced back to pagan times. But none of these analogies, not Pionn's healing cup or the mystic basin which figures in *Peregrin*, can be in any true sense called a Grail. The essence of the Arthurian Grail lies in its character of a Christian relic, and the very name suggests that the conception as it is there presented to us was an Anglo-Norman one. It is very possible, no doubt, that Celtic tradition may have had a share in shaping the conception, but that is all that can be safely said. Some little light, perhaps, is thrown on the question by the curious coincidence between the book presented in a vision in the year 717, which Robert de Borron (*circa* 1190) sets up as the prime authority for his *Saint Greal*, and the vision in the same year in which the Grail itself was seen by a British hermit, as recorded by Helinand in 1204. The return of the first Crusaders stimulated that enthusiasm for

relics of the Passion of which we have a proof in the Sacro Catino at Genoa and its rivals. A very natural consequence would be an eagerness to discover the hiding-place of the true catino, and this, when the Round Table idea had been once imported into the Arthurian story, would furnish the 'deed of worship' *par excellence* necessary to its constitution, while an equally natural consequence would be that the poets in working out the idea would avail themselves of any floating traditions of mystic vessels endowed with miraculous properties which could be pressed into their service. Arthur himself has, no doubt, been treated in the same fashion. Hero-worship is almost always accompanied by annexation. The Charlemagne legend is largely made up of fragments that properly belong to Charles Martel, Pepin, and Charles the Bald. Even in the comparatively modern case of the Cid, one of the most famous exploits, the unsuiting of the French ambassador, is in reality the property of the 15th-century Comte de Cifuentes. It would be strange if so remote a figure as Arthur's did not show signs of some such process; but even if we find there, as Professor Rhys holds, traces of the culture hero, or of the solar myth, the question of his personality cannot be said to be thereby affected. It would be almost as unreasonable to treat him as a purely mythical being on such grounds, as to deny Sheridan's existence because jokes attributed to him are to be found in early editions of Joe Miller. There is very little certainty connected with the construction of the Arthurian story. It seems plain that the History of the Grail, which properly should precede the Quest, was in reality a later composition; and the respective shares of Chretien de Troyes and Robert de Borron in the Grail, Perceval, and Lancelot are pretty clearly defined. But in most other respects the Arthurian cycle deserves the title M. Gaston Paris applies to it of 'déclat inextinguible.' In no case, as Mr Alfred Nutt says, do we possess a primary form; all the versions that have come down to us presuppose something earlier; all is uncertainty, the order in which the component parts were produced, the sources from which they were derived, the authors to whom they are attributable, the relationships of the various versions and forms one to another; and research seems ever to reveal new nebulae and discover fresh clusters of difficulties. Even on the question as to whether the primary form was in verse, as analogy would lead us to expect, we are for the most part left to conjecture. That Breton popular poetry may have contained the germs of Tristram, Perceval, and Lancelot is no doubt a probability; but of one thing at least we may be certain, that veritable creations like the Lancelot of the Arthur story could have had no place in the simple naive *lais* of which we have examples in the translated specimens of Marie de France. The stories may have come from a Celtic quarry, but the building was Anglo-Norman.

It was inevitable that the Arthur stories proper should be followed by romances claiming a supplementary or an introductory character, such as *Meliadus*, *Guiran le Courtois*, *Artus de Bretagne*, and *Perceforest*, but it would be an injustice to treat these, as Dunlop has done, as though they were legitimate members of the Arthurian cycle, nor have they been admitted into it by the compilers or arrangers who have now and then attempted to present it in a consecutive shape. *Facile princeps* of these is our own Sir Thomas Malory, whose work is, as Dr Sommer says in his masterly edition, 'by far the best guide to the Arthur romances in their entirety.' Malory's judgment may not be, perhaps, invariably impeccable. He has not always chosen the best or most poetical form, and he has

left uncalled many beauties of the old MSS. But this may not have been so much his fault as that of the materials with which he had to content himself. Of his general good taste and literary skill there can be as little question as of his English which has made his book one of the classics of his language. Malory, furthermore, as the exhaustive researches of Dr Sommer show, is the sole authority for portions of the series, in particular the story of Gareth in the seventh book. See ARTHUR, GRAIL.

In the romances of the Charlemagne cycle we stand on much firmer ground. It is true that we know even less of the authors than in the case of the Arthur stories, but on the other hand the whole process of production lies plain to view. The starting-point of the legend is undoubtedly the disaster of Roncesvalles, and the *Song of Roland*—not, of course, the *Chanson de Roland* that has come down to us, but some older form, the existence and nature of which are matters of inference—may be taken as the foundation of the whole Charlemagne cycle of romance (see ROLAND). Of this, apparently, we have a prose version at the end of the Latin history of Charlemagne, which pretends to be the work of his contemporary the Archbishop Turpin. Nothing was further from the intention of the writers than to produce a romance; but among the romances, or at the head of them, their work must be placed. About its intention there can be no mistake. By Charlemagne's example it points out the advantages here and hereafter of serving the church liberally and zealously, endowing holy shrines, encouraging pilgrimages, converting the heathen or exterminating them when unconvertible. It records a military pilgrimage to Compostela made by Charles at the call of St James, and is plainly the work of different hands. M. Gaston Paris believed the five first chapters to have been written by a monk of Compostela about 1050; but it is not very obvious why a Spaniard who had his own national legend of Compostela should have gone out of his way to make a patron of a foreigner and an invader. The remainder, he thinks, was written by a monk of Vienna between 1109 and 1119. The book was soon translated into French, and became the chief source of the story of Roland and Roncesvalles, for which it was believed to be the prime authority until the discovery of the *chanson* proved the existence of a common ancestor. The influence of the latter was mainly through the *chansons de geste* of which it was in most cases the model. Of these the number is large. M. Léon Gautier's list enumerates above a hundred belonging to the Charlemagne cycle, and this of course only represents survivors. Only a few, however, gave birth to prose romances. The Roland had been forestalled by the Turpin history, and of the others the majority were in interest too local, not sufficiently popular, or for other reasons unsuitable for prose. The story of Ogier le Danois (who possibly had nothing to do with Denmark, but was merely warden of the Ardenne-mark) was too famous to be left in the verse of Adenes le Roy; the traditions of the struggles between the sovereign and his vassals in Aquitaine, not so much in Charlemagne's time as in Pepin's, lent an interest to Renard de Montanban, the Rinaldo of Italian poetry, but best known as the hero of the *Four Sons of Aymon* (q.v.), a romance that has probably never been out of print since the introduction of printing; and similar reasons, more or less strong, influenced the selection of *Doon de Mayence*, *Maugist d'Agremont*, *Guerin de Montglave*, *Mille et Amys*, *Jourdan de Blarcs*, *Galien Rhetoré*, and divers others. One of the most notable, independently of its connection with Don Quixote, is *Fierabras*. In the 15th century it was translated into prose by one Jean Baignon of Lausanne, who

prefixed to it the early account of Charlemagne by Vincent de Beauvais, and added the concluding chapters of Turpin with the Roncesvalles story, the whole forming a kind of consecutive Charlemagne romance resembling the Arthur compilations. In this shape, and under the title of *La Conquête du grant roy Charlemagne des Espaignes*, it achieved extraordinary popularity, became a regular chap-book, was translated into Spanish by Nicolas de Piamonte, whose version supplied the balsam of which Don Quixote made trial, and from Spanish into Portuguese about the middle of the 18th century; when it was supplemented by an entirely new Charlemagne romance by the translator, a curious proof of the vitality of the legend.

From the lays of the minstrels of the same period there came also many independent prose romances not necessarily connected with any particular cycle: *Valentine and Orson*, which, however, is sometimes linked with the Charlemagne cycle; *Cleomades*, or *Clamades*, where Cervantes found the magic wooden horse, which by a lapse of memory he assigns to *Pierre of Provence* and *Magalona*, another romance of the same kind; *Partenopus of Blois*; *Melusina*; *The Knight of the Swan*, in some respects the most interesting of all, and curious as an illustration of the growth of a romance. Originally a folklore legend of Brabant, the source of *Lohengrin*, the story was turned into a poem and incorporated in the series on Godfrey de Bonillon, who was made a descendant of the Knight of the Swan; then it was annexed by Vincent de Beauvais for his *Speculum Historiale*, from which it passed into the shape of a romance, and was translated into English at the instigation of Edward, Duke of Buckingham, who claimed to be one of the knight's descendants.

Cervantes correctly claims *Amadis de Gaula* as the founder of Spanish chivalry romance, though he may have been in error as to its being the first work of the kind printed in Spain; the Valencian *Tirant lo Blanch* must have preceded it. It was long held to be of Portuguese origin on the bare statement of Góme de Azurara that it was entirely the work of Vasco de Lobeira; but there is ample proof that an *Amadis* was extant in Spain at least as early as the middle of the 14th century, very probably as early as 1300, but at any rate before Lobeira was born. Southey, in whose time the evidence was not forthcoming, may be excused for asserting the Portuguese origin of the romance; but it is strange to find M. Gaston Paris describing it as 'portugais puis espagnol aux XV^e et XVI^e siècles.' Whether this *Amadis* was in verse or in prose is uncertain; we only know from one witness that it was in three books, and Garci de Montalvo, who is responsible for the existing *Amadis*, merely claims to have corrected three books, which previous editors and scribes had left in a corrupt state, and to have added a fourth. Nor is it a certainty that it was of purely Spanish origin. The influence of the Arthurian romances is manifest, but what is far more suspicious is the absence of Spanish colour and indications of Spanish parentage; the names are almost all akin to those of the Arthur stories, the fay Urganda is a distinctly Celtic creation, and the scene throughout is laid on Arthurian ground, Wales, England, Brittany, or Normandy, a choice not easily explained in a romance whose business was to interest Spanish hearers or readers. But whether or not the original may have been some northern French story, it certainly was not, as has been sometimes suggested, *Amadus et Ydoine* in which there is no more resemblance to *Amadis* than there is in *Aucassin and Nicolette*.

The earliest known edition of the *Amadis* (q.v.) is of 1508, but this cannot be the first; it is too near the date of other romances obviously inspired

by it and born of its success, and it is evident that it was finished shortly after the fall of Granada in 1492. The date is significant in its bearing on the curious phenomenon of the sudden outburst of a chivalry romance literature in Spain, just as the middle ages were drawing to an end and other nations were beginning to put away chivalry among the *bric-à-brac* of bygone days. But in Spain it marked the close of a campaign of seven centuries and the end of a national life of sustained excitement. Under the new order of things, the triple despotism of crown, church, and Inquisition, the nobles and minor nobility were left with a superabundance of leisure on their hands, a condition, as every seaside librarian knows, always favourable to the circulation of fiction, so that Montalvo could not have chosen a better time for his venture. But it would be unjust in the extreme to deny to the merits of the *Amadis* their share in the creation of Spanish chivalry romance. In almost every respect, story, incidents, characters, and human interest, it will bear comparison with the best of its predecessors, and as a romance of chivalry, pure and simple, it has no equal. In this lay the secret of its success. For Spain chivalry romance had a reality unknown elsewhere. *Amadis* came to a generation which had seen round Ferdinand and Isabella knights who could match any of Arthur's or Charlemagne's in exploits. Coming at such a time it is no wonder that *Amadis* was followed by a cry for more, and that more was promptly supplied. But *Esplandian*, *Florindo*, *Lasarte*, *Amadis of Greece* were of a very different vintage. It was by Feliciano de Silva, the object of Cervantes' special detestation, that the work of continuation was chiefly carried on. He was a clever man, with a facile pen, and if not imagination, at least invention in abundance, but his greatest gift was his intuitive perception of the tastes of his readers. He perceived that it was not so much recreation as excitement they wanted, and that so far from objecting to rant, bombast, and extravagance, the more they got the better they were pleased. He seems to have been the first author who reduced writing nonsense to a system, and also the first who made a handsome fortune by his writings. The professed continuations formed, however, only a small portion of the romances, more or less in imitation of the *Amadis*, and infected by the style of Feliciano de Silva, the *Felismartes*, *Behanises*, *Oliveros*, which continued to flow from the press until the long line ended with *Policense de Boecia*, two years before *Don Quixote* was sent to the press.

With *Don Quixote*, fittingly, the history of romances as a branch of fiction comes to a close. There are, indeed, two other groups that claim the title, the Pastorals, and those sometimes called the Heroic, an epithet better deserved by the readers who were bold enough to face entertainment in such a formidable shape. But to these quite as much space as their merits entitle them to has been already given (see NOVELS).

Roman de la Rose. See MEUNG, CHAUCER.

Roman Empire. See ROME.

Roman Empire, HOLY (more fully in German, *Heiliges Römisches Reich Deutscher Nation*), the official denomination of the German empire from 962 down to 1806, when Francis II. of Hapsburg resigned the imperial title. The Western Roman empire came to an end in 476 A.D.; Charlemagne sought to reconstitute it when he was crowned emperor at Rome by Pope Leo III. in 800. But the reconstituted empire fell again into fragments and chaos, till Otto the Great succeeded in making a great monarchy again, and was crowned emperor by Pope John XII. at Rome in 962. Thenceforward for more than eight centuries there was an unbroken succession of German princes claiming and in a measure exercising the powers and privileges of Roman emperors. The name of 'Roman emperor' was carefully retained; 'Holy' was added to signify that the empire was now Christian; and 'of the German nation' was sometimes appended to indicate the new nationality that dominated over the old imperial realms. The emperor was the official head of the Christian world, the temporal colleague and rival of the pope. The new German empire of 1871 called itself simply German, and dropped all claim to be either 'Roman' or 'Holy.' See GERMANY; CHURCH HISTORY; Herbert Fisher, *The Medieval Empire* (1899); Bryce's great monograph, *The Holy Roman Empire*.

Romanes, GEORGE JOHN, naturalist, was born at Kingston, Canada, on 20th May 1848, and after a private education in London and on the Continent entered Gains College, Cambridge, and graduated in 1870 with natural science honours. While still at the university he formed a friendship with Darwin, and he has powerfully reinforced his master's arguments in his Croonian, Fullerian, and other lectures, and in his various works—*Animal Intelligence* (1881); *Scientific Evidence of Organic Evolution* (1881); *Mental Evolution in Animals* (1883); *Jelly-fish, Star-fish, and Sea-urchins* (1885); *Mental Evolution in Man* (1888); *Darwin and after Darwin* (1892); *Examination of Weismannism* (1893; see WEISMANN). This most fertile English writer on the theories and philosophy of modern biology died 23d May 1894. His posthumous *Thoughts on Religion*, edited by Canon Gore, showed that, once a defiant agnostic, he had become almost, if not altogether, a Christian; and in this spirit he had before his death revised his *Candid Examination of Theism* (1878). He was F.R.S. and LL.D. See his *Life and Letters* by his wife (1896), and his *Poems* (1896).

Romanesque Architecture, a term invented by Narceise de Cammout a century ago to describe the architecture of the period between the death of Charlemagne (814 A.D.) and the rise of Gothic Architecture (q.v.). It has sometimes (e.g. by D. MacGibbon in previous editions of this work) been extended to cover the whole period from the time of Constantine to the 11th (or

better the 12th) century. But Rivoira places the dividing line between Christian architecture, which is the continuation of Roman imperial architecture, and what follows, at the Italian churches of the 8th and 9th century (e.g. S. Pietro at Toscanella), which he attributes to the pre-Lombardic style. Here, while the main lines are retained, the classical feeling and proportions are gone, and the decoration is rough. This being so, we can hardly agree with C. Ricci, who, writing on the subject of Romanesque architecture in Italy (*Romanesque Architecture*, London, 1925), does not consider it the rise of a new style, but rather attributes to it a number of individual features of church architecture—detached campaniles (which even in Ravenna do not appear earlier), large crypts raised on pillars, with stairs leading to the choir above, the introduction of tombs into the interior, porches and small arcades springing from columns (as seen both in cloisters and as decoration to the exterior), the use of heavy bronze doors, &c. &c. There was, undoubtedly, a persistence of architectural vigour in Lombardy (see LOMBARD ARCHITECTURE) which led to an improvement in construction (coupled with a tendency to extend vaulting over the whole church) and in decoration generally; and this revival influenced not only the rest of Italy but the whole of north-western Europe, including England; while the rise of the Italian communes in the 11th century led to the construction of very fine buildings all over the country, not only churches but municipal palaces and private dwellings. Different varieties developed in various places, but they were only rarely (especially in Venice and in Sicily) influenced by Byzantine art. The great monastic establishments of the various orders are also important both in Italy and elsewhere.

In the 12th and 13th centuries the decoration with *opus sectile* (mosaic of coloured marbles) of floors, pulpits, altars, and even cloisters and façades, was carried out with great success by the masters known as the Cosmati in Rome and Southern Italy.

In Rome itself there is no definite solution of continuity—the classical tradition was too strong, and the influence of Byzantine art slight; while even in Ravenna, where the latter was more strongly felt, a great deal more can be traced back to Roman classical models than has been till recently allowed: and this is especially the case with such features as intersecting vaults, domical construction, the use of arches springing directly from columns, &c. &c. S. Miniato a Monte at Florence shows a similar persistence of the classical style, but with a marked Lombard influence.

See Kingsley Porter, *Medieval Architecture* (1909); Rivoira, *Lombard Architecture* (1910); Bannister Fletcher, *History of Architecture* (1924).

Romania, (1) the name given by the Venetians to the eastern part of the Morea, whence the capital was called Napoli di Romania (see NAUPLIA).—(2) Rumania (q.v.) was sometimes called Romania.—(3) Rumania (q.v.) or Roumania.

Romanesque Interior.

Romano, GIULIO. See GIULIO.

Romanov, HOUSE OF. See RUSSIA.

Romans, a town of France (dept. Drôme), stands on the right bank of the Isère, 12 miles by rail N.E. of Valence. A bridge of the 9th century connects it with Pègue on the left bank. **Romans** owes its origin to an abbey, founded in 837 by St Bernard, Bishop of Vienne. Silk fabrics, shoes, and hats are manufactured. Pop. 17,000.

Romans, EPISTLE TO THE. This epistle, according to the common theory, was written by St Paul to Rome, during his stay at Corinth about the year 58. It belongs to the second group of epistles, and is mainly concerned with the Judaistic controversy. The epistle with which it is most closely related is Galatians—but there is a difference in tone between the two. Galatians is polemical; in it Paul is fighting the battle of his life, and he is merciless in his criticism of the arguments of his opponents. Romans, on the other hand, is more constructive than polemical; there is less passion in its arguments; Paul is in a calmer mood and contents himself with the positive exposition of his fundamental theological principles. The relation between the two epistles is very similar to that which exists between Ephesians and Colossians. Lightfoot compares Galatians to the 'rough model' and Romans to the 'finished statue.' Romans has often been regarded as a compendium of the Pauline theology. Luther, for instance, described it as an *absolutissima epitome evangelii*. This description, however, is difficult to justify, because Romans contains no doctrine of the Church or the eucharist, and there is very little reference in it to eschatology. Probably Moffatt's statement of the object of the epistle is the correct one. 'The purpose of the apostle is to restate, in the light of his experience during the long mission now closing, and in view of the fresh propaganda which he contemplated in the West, the principles of his Gospel for the Gentiles in its relation to Judaism.' (*Introduction to the Literature of the New Testament*, p. 147.)

The common view as to the original destination of the epistle has been challenged in some forms of modern criticism on the evidence of the internal textual data of the epistle. (a) There is good evidence to show that Marcion used a text of the epistle which did not contain the two final chapters. (b) There is considerable diversity of opinion in the Greek MSS. and versions as to the position at which the doxology (xvi. 25-27) ought to be placed. While the most important Greek uncials place it at the end of ch. xvi., other MSS. put it at the end of ch. xiv., a few place it in both positions, and a few omit it altogether. (c) There is a similar discrepancy with regard to the position of the benediction. While the most ancient MSS. place it at xvi. 20, some important authorities insert it after verse 24, and others again after verse 27. (d) Some authorities omit the phrase 'in Rome' in i. 7-15. (e) The long list of salutations in chap. xvi. has always been a difficulty. Is it likely that Paul would have had so many personal friends in a church which he had never visited?

These facts need explanation. Sanday and Headlam think that they can be accounted for by supposing that Marcion omitted the last two chapters because he objected to some of Paul's teaching in them. Hort thinks that the explanation is to be found in the theory that the last two chapters were omitted in the lectionaries as unsuitable for public worship. There is a growing belief, however, among scholars that the textual phenomena can only be explained on the hypothesis that the epistle was issued in several recensions, and was intended to be a 'circular-letter' addressed

to a number of churches. There is no general agreement, however, as to the relations of the different recensions. Kirsopp Lake holds that the epistle was originally a circular-letter written by St Paul at the same time as Galatians, and primarily intended for the mixed churches which had sprung up in the provinces of Syria and Asia, and that its concluding paragraphs were varied to suit the needs of the different communities to which it was addressed. Lightfoot's theory is that the epistle was originally written for the Roman church, and contained even the salutations in chap. xvi.; but it was subsequently transformed into a circular-letter by the omission of the last two chapters, and the placing of the doxology at the end of chap. xiv. Renan's theory is more elaborate. He thinks that our present epistle contains four different recensions of what was originally a circular-letter—(1) a letter to the Romans, chap. i.-xi. and xv.; (2) a letter to the Ephesians, chap. i.-xiv. and xvi. 20; (3) a letter to the Thessalonians, chap. i.-xiv. and xvi. 21-23; (4) a letter to an unknown church, chap. i.-xiv. and xvi. 25-27.

The 'circular-letter' theory adds to rather than diminishes the importance of the epistle. It accounts for the catholic and comprehensive exposition of the gospel which it contains. The apostle is never—at any rate in the general outline of his argument—diverted from his main purpose by local considerations and controversies. He is able to state his position not in the terms of some local community but for the church as a whole. And consequently there is broader sweep in his argument and a more massive movement in his exposition of his theology than in any other of his epistles, except perhaps Ephesians, which is also a circular epistle and written under similar conditions.

The best modern commentaries are those of Sanday and Headlam (1895), Gifford ('Speaker's Commentary'), Jowett, Beck, Donney ('Expositors' Greek Testament'), Garvie ('Westminster New Testament'), Lipsius (1892), Lietzmann (1906). The best discussion of the critical question will be found in K. Lake, *The Earlier Epistles of St Paul* (1911); Hort, *Prolegomena to Romans and Ephesians* (1895); Lightfoot, *Biblical Essays*; Moffatt, *Introduction to the Literature of the New Testament*. See also, New Testament Introductions of Juelicher, B. Weiss, Reuss and Peake; Shaw, *The Epistles of St Paul*.

Romansch (Ger. *Churwalsch*, from the town of Chur), a name applied to the Romance dialect, or rather agglomeration of cognate dialects, spoken from the Grisons to Friuli on the Adriatic. Ascoli includes all varieties under the common name of Ladin, although strictly that term applies to the dialect of the Engadine, as Romansch does to that of the upper Rhine valley. There are dictionaries by Conradi (Zür. 1820) and Carisch (Chur, 1821). See also Ulich's *Chrestomathies* (1880-90), and the books named at ROMANCE LANGUAGES.

Romanticism (through the adjective *romantic*, from *romant* or *romant*, 'romance'; see ROMANCES), a movement in feeling and thought that has transformed the literature and art of most nations, was defined by Theodore Watts-Dunton as 'the renaissance of the spirit of wonder in poetry and art.' It was a revolt against pseudo-classicism; a return from the monotonous commonplace of everyday life to the quaint and unfamiliar world of old romance; a craving for the novel, original, and adventurous; an emphasising of the interesting, the picturesque, the 'romantic,' at the expense, if need be, of correctness and elegance, and the 'current canons of 'good taste.' Deep humour, strong pathos, profound pity are amongst its notes. Romanticism is not necessarily limited to any one period; there are romantic elements in Homer,

Æschylus, Sophocles; the poetry of Dante is eminently romantic when contrasted with ancient classical poetry as a whole; but though what is romantic for one generation tends to become classic—and so tame, though not really insipid—for a later one, and though the romantic is almost inevitably one side of a truly artistic temperament, there are certain epochs that are specially romantic, and certain writers in those epochs more romantic than their fellows. The 18th century was notoriously classic in ideal, or pseudo-classic—conventional, pedantic, academic; and the revolt against spiritual ennui which followed is the romantic movement *par excellence*. The movement arose under various conditions in the several countries, had a somewhat varying character and course, and sometimes tended towards the merely crude and grotesque. In England, the fountainhead of the movement which culminated in the beginning of the 19th century, it may be traced from the Percy Ballads and Chatterton, from Cowper and Blake and Burns, to Scott and Byron, Wordsworth and Coleridge, Keats and Rossetti. In Germany there were tendencies in that direction in Lessing, in Schiller, in Goethe, as well as in the philosophy of Schelling, and the 'Sturm und Drang' period was largely romantic in its temper; but it was Novalis who was the prophet of 'romanticism,' and among the other representatives of the school were the Schlegels, Tieck, Kleist, Fouqué, and Hoffmann. In France beginnings are found in Rousseau, in Chateaubriand, and others; but the great chief of French romanticism is Victor Hugo. Other French romantics are Lamartine, Dumas, Gautier, George Sand, Flaubert, Mürgler. The romantic movement in the three countries is discussed in the articles on the literature of each. The other countries were more or less moved by the same spirit. The influence of Percy's *Reliques* is traced in the article BALLADS. In Germany romanticism included with the love of the mediæval an affection for the oriental; in religion it led some of its notable representatives to Catholic ideals and into the Catholic Church; and in politics it was associated with reactionary conservatism. The aims of the romantics in painting are defined at PAINTING; see also PRE-RAPHAELITISM. In music Weber has been called the 'creator of romantic opera;' but see OPERA. Berlioz is regarded as the type of French romanticism in music.

Romany. See GYPSIES.

Rome, the capital of the modern kingdom of Italy, stands on the Tiber, about 15 miles from its mouth. Roman legend ascribes the foundation of the original settlement on the Palatine to Romulus, at a date corresponding to 753 B.C. The city occupied seven hills, whose summits rise from 80 to 120 feet above the river and the intervening valleys. These hills are believed to have been formed by subærial erosion of beds of soft tufa previously erupted by submarine volcanoes. Of these seven hills, five—the Palatine, the Capitoline, the Aventine, the Cælian, and the Esquiline,—being more or less isolated, were termed *Montes*; and two, the Quirinal and Viminal, being mere spurs jutting out from the tableland to the east, were called *Colles*. The Esquiline is, however, more properly a *Collis* than a *Mons*, being connected by a narrow neck to the tableland, and its two spurs, the Cispinus and the Oppius, were both called *Montes*. The Palatine and the Capitoline, being the most defensible sites, were doubtless the first to be occupied, and this accords with the Roman legend which makes the Palatine the site of the primitive city founded by Romulus, the Capitoline being occupied by a rival Sabine settlement, which, under Tatius the Sabine king, soon

extended to the Quirinal, a contiguous spur of the tableland, separated only by a narrow valley from the Capitoline. We are also told that the Aventine, which after the Palatine and the Capitoline was plainly the most desirable site, was occupied by a colony of Latins in the time of Ancus Marcius, the fourth king. Under Servius Tullius, the sixth king, the Esquiline, together with the Viminal, which is a mere spur of the Esquiline, is said to have been added to the city. These legends conform to the probabilities of the case; and the tombs mentioned below furnish evidence of human habitation at least as early as the 8th century B.C.

The Palatine had considerable natural advantages, being almost completely isolated by two marshy valleys, and only connected by the narrow ridge of the Velia with the Mons Oppius, the south-western extremity of the Esquiline; while the cliffs which surrounded it were a formidable obstacle. It was probably, therefore, not fortified with a wall—the remains which have been found belong to the wall of Servius, which surrounded the whole city. Its neighbourhood to the Tiber enabled it to command the crossing, which must have existed in some form long before the foundation of Rome. The Via Salaria—the salt way—which led from the Sabine mountains to Rome and so to the salt marshes at the river-mouth, is obviously of very early origin; and until the construction of the Via Flaminia in 220 B.C. the Pons Subicius was the only bridge over the Tiber.

Tradition ascribes the building of the Cloaca Maxima, which drained the valley of the Forum and the Velabrum, to the fifth king, Tarquinius Priscus, the first of a powerful race of foreign kings, the Tarquins, from the city of Tarquinii in Southern Etruria.¹ The Tarquins are said to have ruled over Rome in the 6th century B.C., and this chronological statement is supported in a remarkable way by the discovery of tombs, the latest of which are dated down into the 6th century B.C., proving that the valley of the Forum was used as a burial-place until that time. It is not certain whether this cemetery belonged to the Palatine or the Septimontium;² but, in any case, burials must have ceased to take place here after the valley of the Forum was drained and had become the common market-place of the Latin-Sabine settlements on the Palatine and the Quirinal.³

The valley of the Circus Maximus must have been drained at the same time, for tradition ascribes the beginnings of the circus and the assignment of definite places to the Senate and the Knights (where they could erect wooden platforms twelve feet high from which to view the games) to the Tarquins. It is indeed only reasonable to suppose that, after the separate communities had been knit into one, the two valleys no longer served as the defences of one hill only, but became sites of supreme importance for the development of the life of the whole; and the first wall which enclosed the enlarged city, Rome of the Seven Hills, is ascribed by tradition to Servius Tullius, the immediate successor of Tarquinius Priscus, and predecessor of the seventh and last king, Tarquinius Superbus, and may, from its remains, be assigned with fair certainty to the 6th century B.C. We may suppose, if we will, that the Aventine was at first left out of the enceinte, and the wall carried along the south side of the

¹ A noticeable feature in Etruscan cities was the attention paid to drainage. Not only are rock-cut sewers a feature of Etruscan sites, but the system of tunnels for draining the territory to the north of Veii is one of the most remarkable in existence.

² This was a development towards the east of the original settlement on the Palatine, including two spurs of the Esquiline (the Cispinus and Oppius) and the Cælian.

³ The earliest burials are by some assigned to the 11th, by some to the 8th, century B.C.

Palatine. This gives a far better defensive line, avoids the inclusion (which does not seem reasonable) of the place reserved for games and festivals within the area which had to be protected by a wall, and explains the non-inclusion of the Aventine within the pomerium until the time of Claudius.

Of the Cloaca Maxima, little or nothing remains that belongs to the earlier structure; and indeed in the time of Plautus it was called *canalis*, and may still have been open at any rate for part of its course. Some branch-drains, however, on the slope of the Capitol, may still belong to the regal period, and provide examples of the oldest Roman arches in existence.

The remains of the 'Servian' wall that have come down to us belong in the main, however, to its reconstruction after the capture of Rome by the Gauls. Their line can be traced along the entire circuit, and the best preserved portion, with the Porta Viminialis close by, may still be seen in the railway station. Here the wall served as revetment to the *Agger*, a huge mound of earth, and outside it was a ditch, in some places 30 feet deep and 100 feet wide. This method of defence was adopted where the line of the wall had to cross the tableland of the Esquiline, and at other points of weakness; but where possible the wall was carried along the slopes of a hill as a retaining or escarpment wall; and this is most clearly seen on the Palatine, which must have continued to be separately fortified. For 800 years, until the reign of the Emperor Aurelian, the Servian wall formed the only defence of the city. The wall which bears the name of Aurelian followed the outer boundary of imperial times. On the left bank of the river its line still remains unchanged, though it underwent considerable repairs, both in Roman and in Papal days; but on the right bank it has, in the main, disappeared. It enclosed the suburbs which had grown up beyond the Celian, the Esquiline, and the Quirinal, and included two additional hills, the Pincian and part of the Janiculum, as well as the low-lying ground near the Tiber called the Campus Martius, which now forms the busiest and most densely populated part of the modern city. The Aurelian Wall, as it is called, was begun by Aurelian in 271 A.D., and completed by the Emperor Probus in 280. It was constructed in such haste that existing buildings were made use of as far as possible—it has been calculated for as much as one-sixth of its total length—including three sides of the wall of the Praetorian Camp constructed under Tiberius as barracks for his guards. It was restored and partly rebuilt by Honorius, and repaired by Belisarius. It is 12 miles in circuit. The Leonine Wall enclosing the Vatican Hill was built by Leo IV. in 848.

Paul III. began to defend the city by a series of bastions, planned by Antonio da Sangallo the younger; but only a few of them were completed. Pius IV. extended the fortifications of Leo IV., enclosing a larger area between the Vatican and the Tiber; while Urban VIII. fortified the whole of the Janiculum, thus superseding the Aurelian Wall on the right bank. Populous suburbs have arisen to the east, west, and north beyond the walls, while to the south, extensive spaces within the walls are uninhabited. In 1888 no less than 1466 acres, chiefly on the Celian and the Aventine, were occupied by vineyards, fields, and gardens; but this figure is now much lower; while public gardens and squares occupied 106 acres.

Of the monuments of the primitive Forum, one is certainly preserved—the cippus, with its archaic Latin inscription, which still stands near the traditional tomb of Romulus. The whole text is easily read, but one of Mommsen's last pronouncements was that only one word could be interpreted with

certainly—but that was 'recei,' the archaic form of 'regi,' the dative of 'rex': and the inscription itself dates in all probability from the time of the kings.

The tomb of Romulus was closely connected with the Rostra, the raised platform from which the orators spoke, decorated with beaks (rostra) of the ships captured from the Volscian city of Antium. It was situated in front of the Senate House, the Curia Hostilia, which took its name from Tullus Hostilius, the third of the kings of Rome; on the boundary between the Comitium (a rectangular space, constructed according to the rules of augury, with its sides facing the four cardinal points), where the people assembled, and the Forum outside. And it was regarded as making considerable progress in the direction of democratic government when, for the first time, in 145 B.C., the tribune Gaius Licinius Crassus turned his back on the Comitium and began to address the people in the Forum.

On the west side of the Comitium lay the Carcer, the lower chamber of which, the *Tullianum*, a subterranean dungeon, belongs also to a very early period. It has been recently discussed whether it was originally a well-house or a bee-hive tomb. It was the scene of the executions of Jugurtha, Vergetorix, and other enemies of Rome, including the associates of Catiline, executed here in 63 B.C. at Cicero's orders, on a charge of high treason. It was used as a place of execution down to the 4th century A.D., and has become famous in Christian legend as the prison of Saint Peter. The small size of the prison—though it had annexes and an overflow known as the 'stone quarries' (*laurantia*)—is explained by the fact that it was a place of detention before trial or execution, imprisonment as a punishment being entirely unknown to Roman law. The name 'Mamertine' prison is of mediæval origin.

Not far south of the Carcer lay the Volcanal, a very ancient altar of Vulcan, ascribed even to the time of Romulus. It was originally hewn out of the solid rock of the lower slopes of the Capitol, and part of it may still be seen, showing traces of damage (perhaps caused by the Gauls when they captured Rome) and of subsequent repair with blocks of stone coated with cement painted red.

We can also trace, in some of the earliest of the temples of the Forum, scanty remains of the original structure: and we may be fairly certain that they were preserved in the later reconstructions by reason of the sanctity which attached to them. This is an interesting anticipation of the Christian practice which is so familiar to us. Thus, both in the temple of Castor and Pollux, founded close to Juturna's well, where the Great Twin Brethren watered their horses, after bringing to Rome the news of the victory at Lake Regillus in 496 B.C., and in the temple of Saturn dedicated two years earlier, we may see embedded in the massive concrete bases of the stately edifices of the early Empire the blocks of stone which belonged to the far humbler buildings of the infant Republic.

The Temple of Vesta was of even earlier origin, and its neighbourhood to the well of Juturna presents an interesting juxtaposition of the two main elements of primitive life—fire and water. The form of the temple imitated the primitive round hut, and the virgin priestesses represented the unmarried girls, who, while their men-folk were away hunting or fighting, and the elder women tilled the fields, remained at home to guard the sacred fire on which the life of the tribe depended.

Close by was the Regia, originally the house of Numa Pompilius, according to tradition, and by

him given to the Pontifex Maximus, the chief priest, as his residence.

Besides these primitive sanctuaries, the early forum was enclosed by two rows of shops or booths, the *tabernae veteres* and *tabernae novae*, the former on the south, the latter on the north side. Through this open space ran the *Sacra Via*, along which triumphant generals marched with their armies, ascending finally to the temple of Jupiter on the Capitol, considerable remains of the platform of which still exist, belonging to the original temple which was erected by Tarquinius Priscus, according to tradition.

After the end of the 2d Punic War in 201 B.C., a new kind of building, the Basilica, found its way into Rome from Greece. The name means Royal Hall. These were large covered halls which provided shelter from sun and rain, in which courts of law sat, and business was transacted. The first of these halls was built by the famous M. Porcius Cato Censorius in 185 B.C.; in 179 the censors built a second basilica behind the *Tabernae Novae*, which took its name, *Æmilia*, from one of them; while nine years later, T. Sempronius Gracchus, the father of the well-known popular leaders, conqueror of Sardinia, who brought back so many slaves that the market was glutted with them, built a third behind the *Tabernae Veteres*. The erection of these buildings must have considerably modified the aspect of the Forum; but the greatest change of all was made when Julius Cæsar transplanted the *Rostra* from their position between Comitium and Forum to the upper end of the open area of the latter, in front of the Volcanal. On the left the Basilica *Æmilia* was restored at his expense; on the right the Basilica *Julia* was begun on the site of the older Basilica *Sempronia*. The Curia was rebuilt, and the size of the Comitium decreased; the older *Rostra*, with the traditional tomb of Romulus, were buried under a pavement of block marble, still preserved. 'The black stone in the Comitium,' as the antiquarian Pomponius Festus (one of the few archaeologists of antiquity) tells us, 'marks a spot connected with death. According to some, it was intended to serve as the grave of Romulus, but this intention was not carried out, and in the place of Romulus his foster-father Faustulus was buried. According to others it was the grave of Hostus Hostilius, the father of the third king Tullius Hostilius.'

The assembly of the tribes was, at the same time, transferred to the Campus Martius, where, on the west of the *Via Lata* (the first part of the great highway to the north, the *Via Flaminia*, the modern Corso, the most famous street in Rome, and perhaps in the world), a huge covered voting-hall, the *Septia*, was constructed. Further, in order to facilitate communication between the Forum and the Campus Martius, a new Forum was erected to the north-east of the Curia, the Forum *Julium*, an open space surrounded by colonnades, with the temple of Venus Genetrix in the centre.

Such were the splendid projects of Cæsar, who dedicated the Forum *Julium* and the Basilica *Julia* in 46 B.C., and fell less than eighteen months after in the Curia of Pompey under the daggers of his assassins. But in this, as in other respects, his successor Augustus faithfully carried out his trust, and brought his predecessor's schemes to completion; and the Forum proper, as we see it at present, is essentially the work of these two rulers. Almost the only later additions are the Arch of Septimius Severus, with its reliefs commemorating his victories in Mesopotamia, and the group of columns standing on brick bases, which once supported statues, of which the Column of Phocas is one.

The Curia, as it stands, is a reconstruction of the time of Diocletian, but it occupies the site of that of Cæsar.

The *Rostra*, from which Cicero delivered most of his orations, must have been the older platform on the boundary between Comitium and Forum; but we can recognise traces (behind the large platform of the *Rostra* of Augustus) of the structure erected by Cæsar, from which his own funeral oration was delivered by Mark Antony, and to which were nailed the head and hands of Cicero.

Indeed, the very spot on which the body of the great dictator was burnt, at the opposite end of the Forum proper, was hallowed by the inclusion in the façade of the temple raised to his memory by Augustus, of a semicircular niche enclosing the actual slabs on which the impromptu pyre was raised.

In the time of Augustus the two basilicas were both restored, the *Miliarium Aureum* or Golden Milestone set up, with the names and distances of the chief towns of the empire upon it (its pendant, the *Umbilicus Romæ*, the central point of the city, is probably of later date), the temples of Concord, of Saturn, and of Castor and Pollux rebuilt, and the open area of the Forum repaved. Augustus also constructed a splendid Forum adjacent to that of Julius Cæsar; the massive and lofty enclosing walls, the three columns and the podium of the temple of Mars Ultor, are among the most imposing remains in Rome.

The *Sacra Via* proper, from the Regia to the Arch of Titus, owes its present line to the construction by Nero of huge porticoes leading up to the vestibule of his Golden House on the *Velia*; to this line the House of the Vestals was made to conform, and later buildings in this quarter, such as the temple of Antoninus and Faustina and the huge Basilica *Nova*, built by Maxentius, but altered by Constantine, whose name it bears, followed the same orientation.

The Golden House, erected by Nero after the fire of 64 A.D., occupied an enormous area, with its buildings disposed in a great park, of which an ornamental lake formed the centre; but the appropriation of so much of the centre of Rome was an extremely unpopular act, and Vespasian began the erection of the Colosseum on the site of the lake in the very year of his accession. He also built another Forum, the Forum of Peace, of which little remains; while his son Domitian built the Forum *Transitorium* (often called the Forum of Nerva), enclosing the *Argiletum*, one of the most crowded streets of Rome, to connect the Forum of Peace with the other two. Finally, Trajan solved the problem of the connection between the Forum *Romanum* and the Campus Martius by placing his Forum in the centre of the space between the Capitol and the Quirinal. It was the largest of all, and was reckoned one of the wonders of the world. Within the walls stood the Basilica *Ulpia*, which has been partly excavated so as to expose the bases of many of the columns.

Beyond it stands the great column of Trajan, 124 feet in height, with spiral bas-reliefs representing scenes from Trajan's campaigns against the Dacians, forming the most instructive historical monument in Rome. We are shown the march of a Roman army, the construction of bridges, assaults on forts, and all the varied incidents of a campaign, constituting a pictorial record containing some 2500 figures of men and horses. In the same style, but of inferior art, is the Column of Marcus Aurelius in the Piazza Colonna, on the Corso, usually called the Antonine Column. It bears reliefs representing scenes in the Germanic and Sarmatic wars, both waged on the Danube.

The Palatine Hill, which rises to the south-west

of the Forum Romanum, became, as early as the 3d century B.C., a favourite residence; and in the last century of the Republic many of the great men of Rome had houses there—among them Milo, Cicero and his brother, and his opponent Hortensius. And it is the house of the last-named, which Augustus bought and enlarged for his own dwelling, which is generally known as the House of Livius, and is still in part preserved.

His successor, Tiberius, erected the first of the great imperial palaces on the south-west summit of the hill, that known as the Cermalus. Caligula extended it towards the Forum, and we are told that he considered the Temple of Castor as the vestibule of the palace. (That this is no mere rhetorical exaggeration is shown by the discovery, under the floor of S. Maria Antiqua, of an open water-tank, once lined with marble, which must have once stood in the middle of a great peristyle or courtyard, and is orientated with the palace of Tiberius.) Of his bridge between the Palatine and the Capitol, which was destroyed by his successor, no remains, naturally, exist.

Nero had already planned, and in part built, a huge palace which should join the Palatine with the Esquiline (*domus transitoria*), when the fire of 64 A.D., which destroyed it, enabled him to realise his projects in still larger measure. The palace of Tiberius seems to have survived this fire, but to have been seriously damaged in another conflagration in 80 A.D.

It was thus to Domitian, after the imperial residences on the Palatine had been entirely laid waste, that the task of reconstruction fell. It seems likely that he first devoted his attention to the palace of Caligula and Tiberius on the Cermalus; and what is known as the 'Bridge of Caligula,' above the Clivus Victoriæ, is simply a balcony in two stories, which served to finish off, so to speak, the huge arched substructures of this palace—a balcony which may also be traced at the east angle of this vast pile. He also constructed, or at any rate began, a new approach to the Palatine from the Forum on the same site as the vestibule of Caligula; and the great hall known as the Temple of Augustus, and the two halls behind it, which, in the 6th century after Christ, became the church of S. Maria Antiqua, are ante-chambers to a series of inclined planes which lead up from the Forum to the Clivus Victoriæ. But the huge arches which span the road, and which extended the area of the palace considerably towards the Forum, are due to Hadrian. On the remainder of the hill Domitian erected a far larger palace, which was added to, and partly rebuilt, by Septimius Severus, who built the Septizonium to mask its huge substructures, but has otherwise in the main remained unaltered. While this palace was being erected, the main building of the Golden House was, no doubt, still in use; but a fire in 104 A.D. destroyed it, and Trajan erected his huge baths over its ruins (which have recently been excavated), making use of the large reservoir known as the Sette Sale, which had belonged to Nero's palace. Hadrian constructed the temple of Venus and Rome, with its two apses back to back, on the site of the vestibule, and removed the colossal statue of Nero (changed by Vespasian into an Apollo) to the lower ground in front of the Colosseum.

Other temples, besides those already mentioned, include the circular temple by the Tiber, formerly thought to be that of Vesta, now attributed rather to the harbour god Portunus; while the neighbouring Ionic temple, generally known as that of Fortuna Virilis, is probably that of Mater Matuta. Both these are in the Forum Boarium, or cattle-market; and in the adjacent Forum Holitorium, or vegetable market, a group of three more temples

lies beneath the church of S. Nicola in Carcere. Beyond the line of the Servian wall we reach the Campus Martius, a flat plain between the Tiber and the Pincian, Quirinal, and Capitol, originally, as its name implies, used for military exercises, which towards the close of the Republican period began to be utilised for the erection of public buildings. Here is the theatre of Marcellus, begun by Julius Caesar, and finished by Augustus in 11 B.C. in honour of his nephew, who was to have been his heir. In the 12th century it was held as a fortress by the Faffi or Fabii, and later by the Orsini. Two of the three external tiers of arches still stand. Close by is the portico of Octavia, the mother of Marcellus, enclosing the temples of Jupiter and Juno, of which some remains exist; and the theatre of Balbus was not far off. Further to the north lay an earlier group—the theatre of Pompey, with the senate-house in which Caesar was murdered, and the huge portico attached to it—of which nothing remains above ground; and much the same may be said of the Circus Flaminius, one of the earliest monuments in the Campus Martius, which gave its name to the 9th region of Augustus. It was erected in 221 B.C. by C. Flaminius, the conqueror of Cisalpine Gaul, the constructor of the great north road which bears his name, while within the city it was known as the Via Lata, and formed the eastern boundary of the region. To the north we find a group of buildings which in their present form (as far as they are preserved) belong to the Imperial period. To the west of the Septia lay the Iseum and Senapenn of Domitian, then the Therma or Baths of Agrippa (in their present form a work of the time of Alexander Severus, to whom was also due the restoration of the Baths of Nero, not far away), who was also the original builder of the Pantheon—though this was apparently a rectangular building facing southward. Certainly the splendid rotunda, the best preserved of ancient Roman interiors, lighted only by a hole in the roof, is entirely the work of Hadrian, together with the Corinthian portico of granite columns in front of it, facing north, and the halls immediately behind. It was consecrated by Pope Boniface in 609 as the church of S. Maria ad Martyres, and in the Middle Ages acquired the name of S. Maria Rotonda. To the west is the Stadium of Domitian (the modern Piazza Navona preserves its form), and to the north the temple of Hadrian (often called that of Neptune), erected by Antoninus Pius, in which the Bourse is now situated. To the north of this an important cross-street ran east and west, and we find beyond it nothing but sepulchral monuments. Near and under the Chamber of Deputies was a group associated with Antoninus Pius and his successor Marcus Aurelius—the columns erected in their honour (only the latter now stands), and the areas in which their remains were cremated; while some way further north again is the huge circular Mausoleum of Augustus, in the Middle Ages the castle of the Colonna family, and recently converted into a concert-hall. On the east side of the Via Lata we find few public buildings, and the remainder of the more important of them are scattered about in different quarters of the city. Even in the Campus Martius the absence of any scheme of town-planning is very noticeable—the monuments fall into comparatively small groups—while in the rest of the city it is still more marked. This is due to the fact that its topography was from the first dictated by the seven hills and the valleys between them, and by the position of the gates in the Servian wall and the roads that led to and issued from them, the lines of which seem to have remained stereotyped.

The importance of the aqueducts in rendering

possible residence in the hilly parts of the city can hardly be overestimated; and it was their cutting by the barbarian invaders of Rome which caused the hills to be almost entirely deserted in the Middle Ages, and indeed until Sixtus V. constructed the *Aqua Felice* in 1585-7. The first, the *Aqua Appia*, was brought to Rome by Appius Claudius Cæcus, the constructor of the Appian Way, in 312 B.C.; but the second, the *Anio Vetus* (272 B.C.), which took its water from the river Anio, above Tivoli, was far more important. The *Aqua Marcia* (144 B.C.) tapped a series of very fine springs in the floor of the Anio valley, which (though the water is calcareous) still form the main supply of the city of Rome; and after a minor aqueduct, the *Tepula*, (125 B.C.) had been added to the supply, and Agrippa had constructed the *Aqua Iulia* (33 B.C.), and the *Aqua Virgo* (19 B.C.), which is still in use, and provides the best drinking water in Rome, Caligula and Claudius returned to the Anio valley, and by the construction of the *Aqua Claudia* (which made use of the same group of springs as the *Marcia*) and the *Anio Novus*, which drew its water from the river once more, enormously increased the supply (38-52 A.D.). Succeeding emperors either repaired or added to the existing aqueducts, and much was done by Frontinus, *curator aquarum* under Trajan, who nearly doubled the amount of water available by removing the abuses which had crept in. Trajan also added a new aqueduct, which bore his name, from springs on the right bank of the Tiber; and so did Alexander Severus, having recourse to the springs below the Alban Hills, of which Pope Sixtus V. was later to make use for the *Aqua Felice*, while Septimius Severus, his son Caracalla, and Diocletian added to the volume of those already in existence. The work of all the last four emperors mentioned was directly in connection with the large baths which they erected.

The huge Baths of Trajan (until lately wrongly known as the Baths of Titus, which are in reality a much smaller building) covered the main palace of the Golden House, and set the model for the two great establishments of the kind, those of Caracalla (*Therma Antonina*) and Diocletian.

On the low ground, south of the *Colan*, are the ruins of the former: they were begun in 212 A.D., and were completed by Alexander Severus. They were built to accommodate 1600 bathers, and, after serving for centuries as a quarry, are still the vastest, and in their desolation perhaps the most impressive, of all the ruins in Rome. The lofty walls are still standing, and, as all the halls have been cleared of rubbish, the arrangements of Roman *therme* can here best be studied. We see the *Calidarium*, the *Tepidarium* (a comparatively small room—the so-called *Tepidarium* is really a great central hall), and a *Frigidarium*, with an *Exedra* and a *Stadium* or *racecourse*. The outer wall encloses a space of nearly 27 acres, of which the baths themselves occupy more than 6 acres. Even more magnificent were the *Therma* of Diocletian on the summit of the Quirinal, destined to accommodate 3600 bathers. The semicircular curve which forms such a conspicuous feature in the *Piazza delle Terme*, was the *exedra* of these baths. One of the smaller circular halls forms the church of S. Bernardo, while the great vaulted central hall, with its columns of Egyptian granite, was converted by Michelangelo into the magnificent church of S. Maria degli Angeli, while the cloisters of a Carthusian convent built out of the ruins are now converted into a museum, which has been extended into the greater part of the central building of the *Therma*.

Alexander Severus was responsible for the reconstruction of the Baths of Nero near the Pantheon.

The only other large baths that we have not mentioned, the *Therma* of Constantine on the Quirinal, have been entirely destroyed since the 16th century.

We may now turn to the 'spectacular' buildings, in which shows and games were held for the delectation of the public. In the same characteristic Roman style as the theatre of Marcellus is the great Flavian Amphitheatre, which goes by the name of the Colosseum, built for gladiatorial exhibitions, and for the combats of wild beasts. Commenced by Vespasian, it was dedicated by Titus in 80 A.D., and finished by Domitian. It is built in the form of an ellipse, the longer diameter measuring 617 feet, and the shorter 512 feet. It rises to a height of 160 feet, covering five acres of ground. The Venerable Bede saw it still intact, and its ruin probably began with the earthquake in the time of Leo IV. In the Middle Ages it was used as a quarry, but, though so large a portion has been demolished, it constitutes perhaps the most imposing monument of Roman magnificence which is left. The earlier amphitheatres were mostly of wood, and have mostly perished. The site of the Amphitheatre of Statilius Taurus, erected in 31 B.C., is unknown. At the side of the church of S. Croce in Gensalemme are considerable remains of the Amphitheatrum Castrense (or Court Theatre), which was utilised in the construction of the Aurelian Wall, from which it projects, forming a sort of semicircular bastion.

The oldest circus was the *Circus Maximus*, in the valley between the Palatine and the Aventine. It dated from the regal period, but was enlarged by Julius Cæsar, and more than once restored subsequently. It was about three furlongs in length and one in breadth, and is thought on a conservative estimate to have been capable of seating 140,000 spectators. The arrangements of a Roman circus can best be studied in the well-preserved circus on the Appian Way, near the tomb of Cecilia Metella, and built in 311 A.D. by the Emperor Maxentius in memory of his son Romulus. It is 350 yards long and 86 broad. The *meta*, the *spina*, the *carceres*, and the seats for the emperor and spectators can still be traced. An Egyptian obelisk of the time of Domitian, removed from this circus in 1641, now adorns the *Piazza Navona*.

Of the *Circus Flaminius*, built in 220 B.C. on the *Campus Martius* immediately below the northern slope of the Capitoline Hill, few vestiges remain; while nothing is now to be seen of the *Circus* of Nero on the Vatican, the centre of which occupied the hollow between St Peter's and the Sacristy, through which the visitor now drives to the Vatican Museum. While the circuses was designed for chariot races, the stadium was used for foot races, but the plan of both was identical with that of the modern stadium. The *Stadium* of Domitian on the *Campus Martius* is represented by the present *Piazza Navona*, recently renamed the *Piazza Agonale*; while the *Stadium* or *Hippodrome* in the Palatine was so named from its shape, and was in reality simply a walled garden.

The roads leading out of Rome beyond the Servian Walls were bordered by tombs, many of which, on the erection of the Aurelian Wall, were included within the city. On the Appian Way are the tombs of the Scipios, the inscriptions on which, forming some of the earliest contemporary records of Roman history, are among the treasures of the Vatican. Close by four ancient *columbaria* (amongst many others which have been excavated) are to be seen. Outside the Aurelian Wall is the tomb of Cecilia Metella, wife not of the triumvir Crassus but of his son or grandson (the tomb is certainly a monument of the early Augustan period), which in the 13th century was converted into a

fortress by the Caetani family. It is a cylindrical drum of masonry 90 feet in external diameter, with a circular chamber in the centre. Another remarkable tomb is the Pyramid of Caius Cestius on the Via Ostiensis, close to the Porta Ostiensis (Porta S. Paolo) and the Protestant Cemetery. The most magnificent of Roman tombs was the Mausoleum of Hadrian, now the Castle of S. Angelo. It was a cylindrical mass of masonry, 210 feet in diameter and 70 high, standing within a base 275 feet square. The height of the whole tomb is uncertain; it was surmounted by a colossal statue of the emperor. When the Goths besieged Rome, the tomb was converted into a fortress by Belisarius. It afterwards became the castle of the popes and citadel of Rome, and in 1527 was defended against the French by Benvenuto Cellini. Hardly inferior in magnitude was the Mausoleum of Augustus. Two obelisks of Egyptian granite faced the entrance,

Tomb of Cecilia Metella.

one of which now stands in the piazza of S. Maria Maggiore, and the other fronts the Palace of the Quirinal. In all there are thirteen Egyptian or pseudo-Egyptian obelisks which ornament the piazzas or gardens of Rome. Two stand near the Pantheon, close to the sites of the Temples of Isis and Serapis, before which they were originally erected, while two others from these temples stand, one near the railway station, the other in the Villa Mattei. Another, now in the Piazza del Popolo, was brought from Heliopolis (where it had been erected by Ramesses II.) by Augustus, and placed in the Circus Maximus. That in the Piazza di Monte Citorio was also brought to Rome by Augustus. That in the Piazza of St John Lateran, 106 feet in height, is the largest in existence. It was erected at Thebes by Thotmes III., and removed by Constantine to the Circus Maximus. The obelisk in the Piazza di S. Pietro was brought from Heliopolis by Caligula, and placed in the Circus of Nero, near its present site. On the Pincian is an obelisk of Hadrian; and there is another in front of the Trinità di Monti, which is also of Roman date—as is that in the Piazza Navona, which has already been mentioned.

Of the many triumphal arches erected by various emperors in the Forum and elsewhere, the arch of Septimius Severus remains in a fair state of preservation in the Forum, just below the Capitol. At the further end of the Sacred Way is the Arch of Titus, with the well-known reliefs representing the spoils from the Temple at Jerusalem. A little

further south, where the Sacred Way joins the Via Appia, stands the Arch of Constantine, mainly decorated with reliefs from earlier buildings. The so-called Arch of Drusus carried a branch aqueduct to the Baths of Caracalla over the Appian Way, just before the latter passed through the Aurelian Wall. The Arch of Dolabella, built in 10 A.D., is almost hidden in the brickwork of the Aqueduct of Nero, called the Aqua Claudia; and the Arch of Gallienus on the Esquiline, erected in 262 A.D., originally had two side arches as well.

Of the fourteen bridges over the Tiber, three are survivals of the eight or nine ancient bridges. The oldest is the Pons Fabricius, built in 62 B.C. by L. Fabricius, leading from the city to the island in the Tiber. The Pons Cestius, rebuilt by the Emperor Gratian, leads from the island to the right bank of the river. The Pons Ælius, now called the Ponte S. Angelo, was built by Hadrian in 135 A.D. in front of his mausoleum, and now serves as an approach to St Peter's and the Vatican. The Ponte Rotto, or 'broken bridge,' was part of the Pons Æmilius, built in 179 B.C. The Ponte Sisto was built by Pope Sixtus IV. to replace the Pons Aurelius.

Modern Rome.—It is impossible within moderate limits to give an adequate account of Rome, which contains more objects of interest than any other city in the world. A bare enumeration of facts must therefore suffice. The observatory in the Collegio Romano is situated in 41° 53' 52" N. lat. and 12° 28' 40" E. long. The population was 226,022 in 1870, 300,467 in 1881, 462,783 in 1901, 688,561 in 1921, and 709,657 in 1923, and it is still increasing fast. The walls, which enclose over 3800 acres, are 14 miles in circuit, and have fifteen gates. In the last thirty years of the 19th century many thousands of houses were built, miles of streets constructed, and millions of money laid out; and since the war the growth of the city has been even more rapid. Under the strict building regulations adopted in 1887, the streets are much more spacious, and even the tenement houses of a better character; meanwhile the government has carefully guarded against the destruction of buildings of historic or antiquarian interest. During recent improvements and excavations many interesting sites have been laid bare (especially near the Forum), and numbers of statues, busts, inscriptions, and smaller objects recovered. Old Rome stands on the left bank of the Tiber; on the right bank, occupying the Vatican and Janiculum Hills and the low ground between these hills and the river, are St Peter's, the Vatican Palace, the Borgo, and Trastevere. The business part of the city occupies the plain on the left bank between the hills and the river, traversed by the Corso (officially Corso Umberto I.), the principal thoroughfare of Rome, about a mile in length, leading from the Porta del Popolo to the foot of the Capitoline Hill. From the Piazza del Popolo two streets diverge on either side of the Corso, the Via di Ripetta to the right, skirting the Tiber, and the Via del Babuino to the left, leading to the Piazza di Spagna, whence the Spanish Steps, once the resort of artists' models, ascend to the Pincian Gardens, on the site of the gardens of Lucullus, which command a splendid view of the city, and formed, till the advent of motor-cars, the fashionable drive and promenade of the Romans. The Villa Borghese (officially Villa Umberto I.), has now been united with these gardens by a viaduct.

Before Rome became the capital of Italy in 1870, the greater part of the Pincian, Quirinal, and

Esquiline Hills was occupied by villas of the Roman nobles, with extensive gardens planted with ilex and other trees. With two exceptions these have been destroyed, and their sites have been covered with modern houses, and too often by blocks of ugly barrack-like buildings, many stories in height, let out in flats. The once dirty but picturesque mediæval and Renaissance city is assuming the aspect of a modern capital, broad straight thoroughfares having been driven through quarters formerly occupied by narrow streets and mean crowded houses. Of the new streets, the most important are the Via Venti Settembre, from the Porta Pia to the Quirinal, and the Via Cavour and the Via Nazionale, which lead from the railway-station—the first to the Forum, and the second to the lower end of the Corso. This is continued to the west by the Corso Vittorio Emanuele as far as the Borgo, crossing the Tiber by a new bridge. The older foreign quarter lay at the foot of the Pincian, around the Piazza di Spagna, but the higher ground towards the railway-station and the so-called Ludovisi quarter are now quite as much frequented.

Of the palaces, the largest are the Vatican, the residence of the pope, and the Quirinal, now the residence of the king, but formerly a papal palace, in which the conclaves were held for the election of the pope. Many of the palaces of the Roman nobles contain collections of pictures and statuary. Chief among them are the Palazzi Borghese (though the greater part of the collections have now been transferred to the Villa, now government property, as are the Palazzi Chigi, Corsini, and di Venezia), Colonna, Doria, Barberini, Rospigliosi, Farnese. Among the notable villas are the Villa Borghese, standing in a great park below the Pincian; the Villa Ludovisi on the Pincian (now a mere fragment of its former self); the Villa Albani, outside the Porta Salara; and the Villa Medici on the Pincian, now the Académie Française. The gardens of the Villa Mattei, on the Celian, command one of the best views in Rome. The picturesque arches of the Neronian branch of the Aqua Claudia traverse the gardens of the Villa Wolkonsky, now much reduced in size.

Besides the private collections, Rome abounds in libraries and museums. The Collegio Romano, formerly a great Jesuit college, is now occupied by a public library, the Biblioteca Vittorio Emanuele, and by a well-arranged prehistoric and ethnological museum. Etruscan and other pre-classical antiquities from the district round Rome are housed in the Villa Giulia, built by Pope Julius III., outside the Porta del Popolo; while those of the classical period are placed in the Museo Nazionale Romano in the Baths of Diocletian, to which the Ludovisi collection of sculpture has been added. Rome as yet lacks a mediæval museum, though some works of art of this period and of the Renaissance are collected in the Palazzo di Venezia, while the pictures belonging to the government are to be found in the Galleria Nazionale di Arte Antica in the Palazzo Corsini (fine collection of drawings and engravings also). The municipal collections of classical sculpture and antiquities are to be found in the Museo Capitolino and the Museo dei Conservatori (to which an important addition has recently been made) on the Capitol; the two palaces, with the Palazzo del Senatore (built upon the ancient Tabularium) between them, form a fine and dignified group round the Piazza del Campidoglio, in the centre of which is the famous bronze equestrian statue of Marcus Aurelius.

The chief papal collections are contained in the galleries attached to the Vatican, the largest palace in the world. In addition to the private gardens and apartments of the pope, the Vatican palace

comprises immense reception-halls and collections of the highest importance, which can only be mentioned briefly. The walls of the Sistine Chapel, built in 1473 by Sixtus IV., are covered with magnificent frescoes by the great Florentine masters, while Michelangelo painted the ceiling and the 'Last Judgment' on the end wall. The Capella Nicolina, built by Nicholas V., and the Pauline Chapel, built by Paul III. in 1540, are also painted in fresco; the first by Fra Angelico, and the second by Michelangelo. Raphael's stanze are halls covered with celebrated frescoes executed by Perugino, Raphael, Giulio Romano, &c., while the decoration of the loggia, largely designed by Raphael, was entirely carried out by his pupils. The world-famous Vatican Library, with its priceless MSS., its collections of early-printed books, of Christian antiquities, and jewellery, is contained in several large halls. The vast sculpture galleries, with their extensive collections, comprise the Museo Chiaramonti, the Braccio Nuovo, and the Museo Pio-Clementino, which includes the Cortile di Belvedere, containing the Laocoon, the Apollo Belvedere, and the so-called Antinous. The inscriptions are contained in the Galleria Lapidaria, the Etruscan antiquities in the Museo Gregoriano, below which is the Egyptian Museum. The new picture-gallery is on the ground floor opposite to the Vatican Gardens. The Lateran Palace, which is also papal, contains important collections of Pagan and Christian sculpture and inscriptions.

The churches, upwards of 300 in number, are among the most conspicuous features of modern Rome. Many of them are opened only once a year, on the festival of the saint to whom they are dedicated. There are also the churches of the great religious orders, twenty-eight parish churches, and the titular churches of the cardinals. The most noteworthy are the five patriarchal churches, the seven pilgrimage churches, and the eight basilican churches. Others are interesting, either from their early date, their historical associations, from the archaeological or artistic treasures they contain, or from the fragments of earlier structures which they enclose. First in rank are the five patriarchal churches. S. Giovanni, in Laterano, between the Celian and the Esquiline hills, ranks as the first church in Christendom. It dates from the time of Constantine. It was, till the rebuilding of St Peter's, the metropolitan cathedral of Rome and of the western patriarchate. It retains its 5th-century baptistery and the 13th-century cloisters, the most beautiful in Rome. The Santa Scala, brought by the Empress Helena to Rome from Jerusalem, has for centuries been the chief object of veneration for pilgrims. The church itself was burned down and rebuilt in the 14th century, and has been repeatedly altered and modernised. The Basilica of St Peter (S. Pietro in Vaticano), the largest church in the world, was rebuilt in the 16th century from the designs of Bramante and Michelangelo, while Bernini added the colonnade in the 17th century. It was begun in 1506 and consecrated in 1626. It is in the form of a cross, with a vast central dome. The interior length is 611 feet, the height of the nave 145 feet, and the height from the floor to the cross which surmounts the dome 435 feet. S. Paolo fuori le Mura, a vast 4th-century church, was before the fire of 1823 the most interesting church in Rome. It has been rebuilt in a style of great magnificence; it still retains its mediæval cloisters, very similar to those of the Lateran. S. Lorenzo fuori le Mura, occupying the site of a church founded by Constantine, was rebuilt in 578, and enlarged in the 13th century, but still retains the ancient marble and granite columns. The Basilica Liberiana, on the Esquiline, is commonly called S. Maria Maggiore,

being the largest of the eighty churches in Rome dedicated to the Virgin Mary. It is one of the oldest churches in Rome, the nave dating from the 4th or 5th century.

These five patriarchal churches, together with S. Croce and S. Sebastiano, constitute the seven ancient pilgrimage churches. The five patriarchal churches, together with S. Agnese, S. Croce, and S. Clemente, are the eight basilican churches. S. Agnese fuori le Mura was founded by Constantine, and restored in the 6th and 7th centuries. It contains many early Christian inscriptions. S. Croce is a 5th-century basilica, and is said to have been erected by the Empress Helena. S. Clemente is among the most interesting churches in Rome. The upper church dates from the 12th century; the lower, which was discovered in 1857, from the 4th; and below it there are far older buildings dating from the imperial and republican periods, the former including the remains of the house of the saint, and a very well-preserved mithraeum. In addition to the eight basilican churches, others already mentioned conserve the remains of earlier buildings. S. Maria in Cosmedin, one of the most interesting churches in Rome, preserves ten columns of the Statio Annonae, out of which it was constructed, and twenty ancient columns taken from other buildings. It has also a beautiful pavement of the 13th century, of ancient marbles, like many other churches. S. Maria degli Angeli and S. Bernardo are ensconced in buildings belonging to the Thermæ of Diocletian, and S. Pietro in Carcere over the 'Mamertine' prison. S. Giorgio in Velabro, a 7th-century church, was restored in the 13th century, but preserves sixteen of the ancient columns. S. Costanza, outside the Porta Pia, was erected by Constantine, and contains interesting 4th-century mosaics. The granite columns in S. Maria in Araceli, on the Capitol, have been taken from earlier buildings. On the Colian we have SS. Giovanni e Paolo, founded in the 4th century in the house of the saints to whom it is dedicated, and rebuilt in the 12th; S. Stefano Rotondo, a 5th-century church containing the episcopal throne of Gregory the Great; and the interesting church of S. Gregorio, built in 575 on the site of his father's house. On the Aventine are S. Balbina, and S. Sabina, both of the 5th century. On the Esquiline are S. Pudentiana, a very ancient church with 4th-century mosaics, constructed above a Roman private house; S. Prassede, a 9th-century church with ancient granite columns and 9th-century mosaics; and S. Pietro in Vincoli, a basilica which existed before the beginning of the 5th century and was then restored, with twenty ancient Doric columns; it contains Michelangelo's statue of Moses and the supposed chains of St Peter, which were undoubtedly presented to Pope Leo I. by the Empress Eudoxia in 442. On the right bank of the Tiber are S. Crisogono, a 12th-century church with ancient porphyry columns and a fine mosaic pavement, and (as so often) remains of the Roman house in which the original church was founded lying below: S. Maria in Trastevere, a 5th-century church rebuilt in the 12th century with twenty-two ancient columns, some fine mosaics, a splendid marble pavement, with numerous interesting early inscriptions in the portico; S. Cecilia has 9th-century mosaics; while the Piazza of S. Pietro in Montorio commands the finest view of Rome. S. Maria sopra Minerva, near the Pantheon, the chief Dominican church, is the only Gothic church in Rome. Among the largest of the 16th- and 17th-century churches are the Gesù, the gorgeous church of the Jesuits, containing the tomb of S. Ignatius Loyola; S. Carlo al Corso; S. Andrea della Valle; S. Maria della Vallicella, commonly called the Chiesa Nuova; and the

Cappuccini, with its ossuary and Guido's picture of St Michael.

One of the greatest improvements which have been effected in modern Rome is the embankment of the Tiber, and the straightening and deepening of its channel. This has put a stop to the disastrous floods by which the lower parts of the city were formerly inundated. The opening of new streets and the widening of old ones have also had a favourable result on the public health; and we should remember that the Renaissance popes dealt just as ruthlessly with mediæval Rome. An extensive system of electric trams is in operation, and both these and the electric light and power are worked from high-pressure cables connected with hydraulic power stations in the upper Anio valley and at Terni.

In addition to the objects of interest which have been briefly enumerated are the vast Catacombs extending underground for many miles, which are situated on all the ancient roads radiating from Rome, and the Protestant Cemetery with the tombs of Keats and Shelley. The best panoramic views of Rome are from the Pincio, the Villa Mattei, S. Pietro in Montorio, the Janiculum, the garden of the Priorata di Malta, and from the huge monument to Victor Emmanuel II. on the Capitol. The new Passeggiata Archeologica, or Archaeological Park, which includes the Baths of Caracalla and their surroundings, will preserve from modern constructions an interesting part of ancient Rome.

For the clearness of the atmosphere, it is fortunate that there are practically no manufactures in Rome. Hats, gloves, neckties, false pearls and trinkets are made, and there are cabinetmaking and foundries on a small scale, but, compared with other great cities, the absence of factory chimneys is very notable. There are printing-offices, but the Italian book trade is centred at Milan. The chief industry is the manufacture of small mosaics, of small bronzes, of statuary, casts, and pictures, either originals or copies of the works of the great masters. The prosperity of the city depends on the courts of the Quirinal and the Vatican, on the army of functionaries in the public offices, on the numerous banks and businesses which have either main or branch offices in the capital, on the garrison, and on the foreign visitors who crowd the hotels during the winter months. The railways from all parts of Italy converge outside the city, which they enter near the Porta Maggiore on the Esquiline, and have a common terminus on the summit of the Quirinal.

ROMAN HISTORY.—Rome, the 'Mistress of the World,' the 'Eternal City,' gives name to a political empire which lasted eleven centuries, till its transfer to Byzantium, where it lasted eleven centuries more; also to a religious empire which since 42 A.D. has acquired spiritual sway over a yet larger dominion than its pagan predecessor, and which, in accord with Imperial Germany, formed the twin factor of the Holy Roman Empire, dissolved in 1806.

Colonised in the Iron Age by Alban shepherds who migrated from their hills in fear of volcanic disturbance, Rome, according to her officially adopted legend, dates from 21st April 753 B.C., when Romulus, first of her seven kings, settled on the Palatine mount. From his quadrilateral stronghold—*Roma quadrata*—he made conquest of the Capitoline and Quirinal. After his successor

Numa, the Clelian was annexed by Tullus Hostilius and the Aventine by Ancus Marcius. To the hills, now five under Tarquinius Priscus the fifth king, were added the Esquiline and Viminal by Servius Tullius, who walled in the seven with a stone fortification. So that under her seventh and last king, Tarquinius Superbus, the City of the Seven Hills was already 'built for empire,' on marshy soil made habitable by drainage, and connecting with the sea-board by the Tiber. The derivation of 'Rome' and 'Romulus' from the *Ramon* or 'river' has recently been disputed, and that from *Ruma*, 'breast,' has been proposed.

Latin in population, with a Sabine infusion, Rome was divided into three tribes—the Ramnes, the Tities, and the Luceres, and again into thirty *curiae*. The tribal division disappeared early; that into *curiae* lasted well into republican times. Out of the *curiae*, originating in common religious observances, grew the *populus Romanus*, including all freeborn Romans. Its king (*rex*) was not always hereditary either in his regal or his religious capacity, nor merely elective. When a king died, his successor was chosen by the heads (*patres*) of families (*gentes*). These *patres*—the guardians of religious observance, of popular right, of state interests had power to choose a provisional king (*inter-rex*), who, with the *patres* for assessors, decided on the new king, who was then proposed to the *curiae* in assembly (*comitia curiata*) and, if approved, confirmed by the *patres*. The king had now absolute authority, civil, religious, and military. The *patres* were his counsellors the senate—having the above indicated powers, always subject to the king, who consulted them at pleasure, and filled up vacancies. In solemn assembly the Romans met in the Forum under the king or *inter-rex*, who put questions to the vote, when each *curia* voted in turn, its vote being determined by the majority within itself, and the preponderance of these votes deciding the result.¹

Romulus, Numa Pompilius, Tullus Hostilius, and Ancus Marcius—the first and third Latin, the second and fourth Sabine—are little more than legendary names; the warrior chief Romulus typified by his *Rome quadrata* and *Comitium* or place of assembly in the Forum; the priestly Numa by his Temple of Vesta and his Regia close to it; the statesman Tullus Hostilius by his Senate House (*Curia Hostilia*); and the administrator Ancus Marcius by his state-prison, his bridge across the Tiber, his fortification of the Janiculum, and his founding of the seaport Ostia (where no traces of habitation at such an early date have been found). The last three kings, probably powerful Etruscan rulers who extended their sway over Latium, are of a very different character, and far more wealthy and powerful than the simpler native rulers. In Tarquinius Priscus (616-578 B.C.) we have an Etruscan and less shadowy Romulus, admitting into the senate a hundred new *patres* from conquered Latin states, and laying out the Circus Maximus for the entertainment of the people. Servius Tullius, on Tarquin's initiative, distributed all freeholders (for military purposes primarily) into tribes, classes, and centuries. Drawn up in order of battle, the centuries (bodies of one

hundred) in front were composed of the wealthier citizens as better able to equip themselves for attack; behind them came the centuries of the second and third classes, poorer and less fully appointed—the three forming the heavy-armed infantry; while centuries of the fourth and fifth classes, poorer still and correspondingly equipped, held the rear. The full strength of the freeholders was divided into two equal parts—the *seniores* and the *juniores*, the latter engaged in active duty, the former as reserves. Each corps consisted of 85 centuries or 8500 men—i.e. of two legions, each about 4200 strong, auxiliary to which were the sappers and trumpeters. Finally, the six centuries of cavalry were supplemented, from the wealthiest citizens, by twelve more. For the army thus organised Servius drew levies from his four regions, corresponding to his four tribes, the Suburan, the Palatine, the Esquiline, and the Colline. These tribes included freeholders outside the gates, also entitled to meet and vote with the centuries at their *comitia (comitia centuriata)*. Under her seventh and last king Rome became formidable throughout Central Italy, and owed to him the Temple of Jupiter Capitolinus, and the *Cloaca Maxima*—the drainage system tapping the hills around the Forum and carrying the waste into the Tiber. But Tarquin's rule was so masterful as to drive the people to revolt, the last provocation being his son's outrage on the noble Lucretia. When engaged at a siege near the coast he was dethroned; he and his race were exiled in perpetuity, and regal government replaced by the Republic. Three great efforts to reinstate him were defeated, and he died at Cumæ.

The Republic.—After their successful revolution, the patricians made their power so felt by the plebeians as to start a conflict between them lasting two hundred years. The king was now represented by two *consuls*, elected annually, and from the patrician order. The plebeians, freeborn citizens as they were, retained their votes by classes at the *comitia curiata* and by centuries at the *centuriata*, but many of them were attached as clients to patricians who commanded their votes, and all of them were excluded from the higher offices of state. Unable to elect one of themselves consul, the plebeians had not even the power to carry the patrician candidate they favoured, being in a minority in the *comitia centuriata*, and, again, in a greater minority in the ultimate and decisive assembly, the *comitia curiata*. The absolute authority wielded by the consuls they felt to be still more oppressive when, in state crises, it was merged in a dictator; so their first attempt to safeguard their liberties and lives was directed at the consular power. The first advantage they gained was the 'right of appeal,' by which no magistrate (the dictator excepted) could subject a Roman citizen to capital punishment unless with approval of the *comitia centuriata*. Power to extort such rights the plebeians possessed in their military capacity, refusing, as soldiers, to serve unless their demands were conceded. The secession of their legions to the Mons Sacer, on the Anio three miles off, secured them annually elected magistrates of their own, *tribuni plebis*, with power to protect them against the consuls. From two the tribunes were increased to five, and by 449 B.C. to ten. In no sense a magistrate, the tribune was a check on authority, and his power developed gradually till the tribunate, formidable at the close of the Republic, became still more so under the empire. By the Pablian law (471 B.C.) the assemblies convened by the tribune (*concilia plebis*) were made legal; not yet their decisions (*plebiscita*). At these the voting was by tribes, not by *curiae* or centuries, whence the object of

¹ Such was the tradition, but it is of patrician origin. Hultsen has recently pointed out that, of the names of the seven *montes* of the Septimontium—three (the Celius, Cispius, and Oppius) are identical with those of plebeian *gentes*; and that the names of the kings, with the exception of Romulus and the Etruscan Tarquins, are also plebeian. On the other hand, the first sixteen *tribus plebeiae*, founded, according to tradition, in 465 B.C., fifteen years after the expulsion of the kings, are all patrician; and the conclusion is obvious—that the patricians were those who had effected the revolution, while the plebeians were the partisans of the old order, and the real founders of Rome.

the tribunes was to add as many to the tribes as possible. To become member of a tribe it was necessary to be a freeholder, and so the tribunes, to multiply freeholders, agitated to secure for the plebeians their share of the *agri publici* or state-lands. Having partially succeeded in this, they won another advantage from the ever-resisting patricians—the appointment for one year of a commission of ten patricians (*decemviri*) to make public a code of law binding on patrician equally with plebeian. This code—the famous Twelve Tables—substituted written and published law for that unwritten code which, confined to the patrician few, was always interpreted in their interests. An attempt to reappoint, possibly to perpetuate, the decemvirate caused another secession; the consuls were again created; and from the growing vantage-ground of their *concordia*, increased by accessions to the plebeian order from without, the tribunes extorted the recognition of the *plebscitis* as legally binding on patricians. The *concilia*, now become *comitia tributa*, could henceforth carry reforms which, if sanctioned by the patres, had the validity of state-law. Another concession gained was intermarriage between plebeian and patrician, and thereafter the consulate—still the patrician stronghold—was attacked. The two consuls were replaced by six military tribunes drawn from either order. Of these consular tribunes the plebeians generally had the majority until, obstacles and delays notwithstanding, the Licinian and Sextian laws were passed (367) replacing the consular tribunes by consuls, two in number, of whom one at least should be a plebeian; enlarging the priestly college from two to ten functionaries, of whom plebeians were to constitute half; relieving the poorer plebeians from debt; and promoting their interests by advantageous reforms in the ownership and cultivation of land. Patrician monopolies shrunk rapidly. In 356 the dictatorship, in 350 the censorship, in 337 the praetorship, and in 300 the colleges of pontiffs and augurs were thrown open to plebeians. The *patrum auctoritas*, or control by patricians of the decrees (*plebscitis*) of the people in assembly, became a dead letter; and the two hundred years' conflict issued in the recognised validity of all measures carried in the *comitia tributa*—a conflict memorable not only for the ability displayed by either order, but for the respect for law observed equally by both.

For her first fifty years of republican life Rome expanded little; in fact, the fall of the Etruscan dynasty probably led to a diminution in the extent of her sway. Nearest her were the Latins, the Volscians to the south-east, the *Aequians* to the east, and the Hernicans between the two last. Allying herself with the Latins and Hernicans, she kept the Volscians and *Aequi* in check till her policy became triumphantly aggressive in the sixty years between 449 and 390. Having razed the south Etruscan stronghold, Veii, she pushed northward to the Ciminian forest, whence she drew down on her the Celtic conquerors of north Etruria, who, defeating her on the Allia, took and sacked the city, all but the Capitol. Recovering rapidly from this disaster, she riveted her hold on south Etruria, gradually subjugated her old enemies and allies, the Volscians, *Aequians*, Latins, and Hernicans, and dominated Central Italy from the Ciminian forest to the Latin shore. The Sabellian tribes of the Apennines now gave her trouble. The most powerful of these, the Samnites, had overrun Campania; but from this she dislodged them, and, in spite of a formidable revolt extending from the Sabine Hills to the Latin shore and Campania itself, she made good her command of plain and seaboard, lying compact and firm between north Etruria with its detached cities,

the Apennines with their miscellaneous tribes, and Southern Italy with its enervated Greek population. The Samnites, in a second war lasting twenty-two years, failed to get the better of her; in a third, with the northern Etruscans and the Celts as allies, they made a last attempt to crush the growing giantess. This too she defeated after desperate conflicts in which she purchased victory dearly: the Celts were shattered; the Etruscans bought peace by heavy indemnities; and the Samnites on honourable terms became her allies. In characteristic fashion she proceeded to consolidate what she had won, planting 'colonies'—i.e. agricultural garrisons—of Roman citizens wherever their presence was required at strategic points, connected by military highways with the capital, and in this way controlling Central Italy from Adriatic to Mediterranean. The network of roads, which from small beginnings (which can be traced in her earliest days) thus gradually sprang up, spread Roman influence and civilisation all over Italy, and eventually over the whole known world. At the invitation of Greek Tarentum, beset with marauding hordes, she successfully intervened in the south, till in turn Tarentum, incurring her hostility (281–280), brought King Pyrrhus of Epirus to repel her. At first the Epiriotes prevailed, but their two victories were as costly as defeats, and in a third great battle at Beneventum (275) they were so punished that Pyrrhus returned to Greece. The fall of Tarentum shortly after left Rome dominant in the peninsula from the extreme south to the Liguian and Celtic frontier. *Divide et impera* was her policy.

Detaching the subject states or tribes from each other to draw them more closely to herself, leaving them 'home rule,' but reserving the safeguard of coast and frontier and power to make peace or war with the outside world. Among her outlying communities the colonies of *cives Romani* above mentioned ranked first; next came those Latin towns which enjoyed the full franchise, this being sparingly conceded to other communities, of which the lowest received civil but not political rights, their members excluded from the tribes, and, as soldiers, serving not in Roman legions, but in contingents apart. To the urban communities within her pale Rome gave self-government liberally, with assemblies, senates, and magistrates, always, however, subject to the central authorities—the Roman consuls, praetors, and censors. For the administration of justice these colonies and enfranchised towns were annually visited by the praetor's representatives, called praefects, who also assumed control of such communities as were without local government. The military system was modified till the old citizen army, with its order in battle determined by civic rank, became the professional institution in which superior fighting power and experience were primary considerations to be paid for accordingly. On distant campaigns the consul in command received extension of his *imperium*, out of which grew the 'proconsul,' empowered to hold the field till the war was at an end.

Eleven years after her victory over Pyrrhus Rome engaged with Carthage in her mighty struggle for the empire of the Mediterranean. To secure her expansion westwards she had first to expel the Carthaginians from Sicily. Having gained to her side the Syracusan king Hiero, she took Agrigentum, and in 260, with her first naval armament under the consul Duilius, she signally defeated Carthage on Carthage's own element. Following up this advantage, she transferred the war to Africa, and was at first so successful as to recall a considerable part of her forces. But her consul Regulus, whom she left behind, was worsted and made prisoner, a series of naval disasters en-

sued, and Carthage seemed about to regain more than she had lost of Sicily, when the consul Catulus (241), in command of a splendid fleet, gained a decisive victory over the Carthaginians, who thereupon undertook to evacuate Sicily and the adjacent Lipari Islands. This ended the first Punic war, twenty-two years in duration, the result to Rome being her acquisition, not only of Sicily, which she henceforth governed as a 'province,' but (a few years later) of Sardinia and Corsica, also governed like Sicily by magistrates sent every year from the capital. Finding Rome her match at sea, Carthage resumed hostilities by acquiring a foothold in Spain, which was to become her military basis for further operations against her rival. Under Hamilcar, the great general who conceived this plan, she occupied the peninsula as far as the Tagus; Hasdrubal continued the work of subjugation till his death (221); and finally Hamilcar's son Hannibal, who, with more than his father's genius, shared all his father's antipathy to Rome, pushed the conquests of Carthage up to the Ebro.

Meanwhile Rome herself was engaged in subduing the Celts in the valley of the Po, and having planted three colonies—Placentia, Cremona, and Mutina—to safeguard her new possessions, and completed the great road to the north—the Via Flaminia—as far as Ariminum, she turned her attention on Spain, and got Carthage to make the Ebro her northern boundary in the peninsula. But such engagements could not long be respected. Saguntum, a Greek colony in alliance with Rome, on the east coast of Spain, was besieged and taken by Hannibal, though a Roman embassy to Carthage had protested against the operation. The second Punic war was declared in 218, and Rome sent one army under P. Cornelius Scipio to Spain, and another under T. Sempronius Gracchus through Sicily to Africa. But Hannibal's plans, long matured in secret, were carried out with unexampled celerity. Scipio had got no farther than Massilia, when Hannibal, having crossed the Pyrenees, was already at the Rhone; and after fighting his way over the Alps against every obstacle—the hostility of the tribes included—descended on Cisalpine Gaul with but 26,000 surviving of his army of 59,000 men. Defeating the Romans on the Ticino and the Trebia, he realised his expectation of getting the Celts to join him, and in the spring of 217 he pushed on to the city through east Etruria. He annihilated the consul Flaminius at Lake Trasimene; and from Spolegium within a few days of Rome he turned eastward, plundering as he went, and paused for supplies in north Apulia. The Romans, now gravely alarmed, elected a dictator, Quintus Fabius Maximus; but his masterly inactivity did not satisfy them, and they sent two consuls with a numerous army to hurl back the invader. In the great battle of Cannæ Hannibal's victory was complete—the Romans losing 70,000 men to Hannibal's 6000, and Southern Italy—all but the Latin colonies and the Greek coast-towns—came to his side. Macedonia and part of Sicily declared for the conqueror, and the Greek communities one by one were surrendering to him. The Romans tried to recover Campania and laid siege to Capua, and this brought Hannibal up from Tarentum. He even marched directly on Rome herself and rode up to the Colline gate; but he retired unable to make any impression on the city and its defenders; he conciliated no allies; and fell back on South Italy, leaving Capua an easy prey to its besiegers. Five years had done little to encourage the Romans, till Hasdrubal, defeated in Spain, crossed the Alps and skirted the east coast of Italy, to reinforce Hannibal in the south. But he was beaten and killed on the Metaurus by Nero, who, turning southwards, marched up to Hannibal's

camp and threw Hasdrubal's head into it. The war in Italy was virtually at an end. Hannibal's attempt on Rome had failed. Meanwhile young Publius Scipio, having driven the Carthaginians from Spain, returned to the city with the proposal to descend on Carthage herself. The senate, not without misgiving, consented. Scipio's successes in Africa compelled Hannibal to leave his vantage ground in Southern Italy and come to the aid of his hard-pressed compatriots. The great battle at Zama left Scipio the victor, Hannibal a fugitive, and Carthage suing for peace. Her request was granted, and she retained her territory, but bound herself to undertake no wars outside Africa and (without the consent of Rome) no wars inside. She surrendered nearly all her navy and had to pay an indemnity of 10,000 talents in fifty years. Rome was now (202) mistress of the Mediterranean, but she had to consolidate her acquisitions. Sicily, easily ruled under a praetor, became her granary and the provision store for her legions. Spain, however, required praetors invested with consular power and a permanent garrison of four legions to keep her in order. The insurrection of Viriathus lasted till the fall of Numantia after a memorable resistance; and not before Scipio Africanus the younger took it in hand could the country really be called pacified and its rich resources made available. Meanwhile Rome had a secret dread of the resuscitation of Carthage, and she courted every pretext for renewing war with her and razing her to the ground. That came in 151 when Carthage, goaded by Masinissa's forays, broke her treaty obligations to punish him. In 149 Rome laid siege to her, and by 146 she was stamped out from the roll of great cities. Her territory was now the Roman province of Africa, protected by Masinissa's three sons, who ruled Numidia. In Italy herself the cities that had declared for Hannibal were severely punished. In the north the Celts forfeited their separate political existence. In the south Roman settlers occupied confiscated lands—nearly everywhere but in Apulia and Lucania; and even the Latins soon felt the preponderance of the Roman element, which tended more and more to assert itself.

Fifty years after she became mistress of the west, Rome had also become the mightiest state in the east, first by conquering Philip of Macedon, who had been the ally of Hannibal, and whose ambition to dominate the Ægean drew Rome into the second Macedonian war (200), which ended in Philip's defeat at Cynoscephalæ and the reduction of Macedon to a minor power. Next came the 'liberation of Greece,' which, with the alliance that followed, enabled Rome to proceed against Antiochus, king of Syria, who in 197-196 had overrun Asia Minor and penetrated into Thrace. Beaten by land and sea, Antiochus sustained a decisive defeat at Magnesia in Asia Minor, and fell back behind the Halys and Taurus range, to the west of which all the kingdoms and communities were now under Rome's protection. Western Greece, however, began to give trouble, and Philip of Macedon's successor, Perses, incurred a final encounter with the Romans in a third Macedonian war, terminating in his utter rout and capture at Pydna (168). So that, twenty-two years thereafter, Macedonia had sunk into a Roman province, whose governor came gradually to control the Greek states till the whole peninsula was subservient to Rome. Steadily strengthening her hold on Asia Minor, Rome further assumed the guardianship of the king of Syria; while in Egypt, which in 168 had acknowledged her suzerainty, she restored a *protégé* of hers to the throne, at the same time, true to her policy, dividing and weakening his power. From Syria to Spain the Mediterranean was now a Roman lake, but her authority

was better established in the west than in the east. In the former her provincial government was fairly established; not so in the latter, which, besides its more elastic frontier, possessed a civilisation in some respects superior to her own.

With the establishment of her supremacy without began Rome's troubles within. The ennobled plebeians (*nobiles*) combined with the old patrician families (*optimates*) to exclude all but themselves from high office or the senate. The constitution had become an oligarchy in which the comitia, nominally supreme in electing magistrates and passing laws, were practically superseded. The prestige of having saved Rome from Hannibal and raised her to undisputed empire belonged to the aristocratic senate, while the graver disasters (at Trasimene and Cannæ) were due to the people's favourites. But that prestige was getting gradually impaired by economic failure at home and confusion abroad, and the people were availing to a sense of the power the senate had taken from them. The small holders, particularly in Etruria and South Italy, burdened with military service and competing vainly with foreign importations of corn and labour, deserted the farms on which they could neither thrive nor live, and the multiplication of colonies throughout the peninsula gave but temporary relief. To arrest the imminent annihilation of these freeholders—Rome's main-stay—Tiberius Gracchus, the tribune (133), proposed his reform, which was practically the first of a series of attacks on senate-rule. Occupiers not recognised by the Licinian law were to be evicted; occupation was not to extend beyond 1000 acres; public grazing-lands were to be reclaimed for tillage. The senate opposed him strenuously, and he was killed in an incidental collision; but his struggle was renewed on a larger scale by his brother Gaius, who curtailed the senatorial power by getting the comitia to deprive it of privilege after privilege. He, too, fell in a brawl, and by 111 his reforms had already been frustrated and a quite new aspect given to the agrarian question. But the popular party had been taught its lesson by means of the tribunate to reassert its power in the comitia to work out its salvation. Gaius Gracchus had been dead ten years when the client-state Numidia was seized by Jugurtha, who had supplanted its legitimate governors and insulted the Roman name. The popular leaders insisted on his chastisement; but the war, mismanaged under patrician officers, was carried to a triumphant close by the people's favourite, the low-born, illiterate, but efficient Marius, who in January 104 brought Jugurtha in chains to Rome. Still greater successes awaited their hero. Having annihilated the Cimbri and Teutones, who had inflicted four defeats on the patrician generals, and been made consul for the sixth time, he aided the popular vindicators, Saturninus and Glaucia, to harass the senate. But the advantages they secured were small, their violence had to be curbed by Marius himself, and at last the populace turned upon and killed them. The rise of Marius, however, was fraught with far-reaching results. His six consulships, his intervention as a soldier in politics, his military reforms, by which all classes, irrespective of rank or means, were admitted to the legion, and the compulsory levy replaced by volunteer service under a popular leader were epoch-making in the revolution.

The commercial class—soon to develop into the equestrian order—had by their power in the courts and their increasing exactions as farmers-general (*publicani*) been at feud with their controllers, the magisterial class in the provinces, and fiscal reform became urgent. The Italian communities—the allies of Rome—had long felt their burdens increase as their privileges waned, and they demanded their

share of the conquests they had helped to achieve. Promises of relief and expectation of securing the Roman citizenship had brought them in crowds to the capital, to be driven back again by an exclusive senate and people. The tribune Drusus strove to bring about fiscal reform and the redress of the Italians, but though he carried his laws he could not make them valid, and finally he was assassinated. The equestrians remained supreme in the courts, while the murder of Drusus roused the irritated Italians to rebellion (90-89) in the central highlands and the south especially. The Social War began, the insurgents aiming at the erection of a new Italian state governed on the lines of the Roman constitution. To suppress them the two consuls of the year, each with five legates, including Marius and his future rival Sulla, headed the legions, but were disastrously beaten. In the north, however, Marius and Sulla, and in Campania the consul Cæsar, were partially victorious, but so partially that reform after reform had to be conceded, till the Italians could obtain the franchise merely for the voting. The war at length died out by the absorption of the insurgents into the Roman citizenship; but the internal troubles continued. The new citizens enlarged their political claims, the senate was distracted by personal feuds, economic distress prevailed among all, and a war with Mithridates threw Marius and Sulla into rivalry as to which should command the expeditionary force. The action of the tribune Sulpicius in dealing with this complicated crisis intensified it the more. He introduced laws to entrust Marius with the Mithridatic campaign, to allow the new citizens to vote in all, not in a restricted, number of tribes, to confine the freedmen to the four urban tribes no longer, to unseat any senator more than 2000 denari in debt, to recall from exile those suspected of complicity with the Italian insurgents. Every one of these proposals, bitterly contested, would yet have become law but for the consul Sulla, who, heading in Campania the legions assigned him in the Social War, marched on Rome—the first consul who ever invaded her with her own troops. The flight of Marius and Sulpicius left him free to impose arbitrary measures, among them that by which the sanction of the senate was required before any bill could be entertained by the comitia; and, having seen the consular elections safely through, he set out against Mithridates (87).

In his absence Cinna attempted as consul to carry the reforms of Sulpicius, but was driven from Rome amid the massacre of the new citizens in voting assembly. He in turn rallied round him the legions in Campania, and joined by the veteran Marius, who reappeared from Africa, he entered Rome and was recognised as consul, as was Marius himself (for the seventh time). After a brutally vindictive massacre Marius died (86), and Cinna remained supreme, securing the consulship to himself and a confederate, and getting the newly-enfranchised Italians enrolled in all the tribes. In 84 he died, and next year Sulla, having concluded a peace with Mithridates and left Asia tranquil, landed at Brundisium with a powerful army, including many of the *nobiles* who had fled from Cinna. Resistance, nowhere formidable, he quickly overcame and (82) entered Rome, to find his lieutenants triumphant in North Italy and to annihilate the remnants of the Marian party just outside the city. But he failed to use his power, absolute as it was, for the abatement of long-standing evils and the prevention of coming disasters. Triumphant everywhere, he instituted a reign of terror—slaying, proscribing, and confiscating through revenge or suspicion. For nine years his rule as dictator, in spite of much salutary administration, was marked by a remorseless partisanship which left the future

to take care of itself—creating in the sons and heirs of the proscribed and dispossessed the handy tools of agitation, justified as this increasingly became by ruined agriculture, by the multiplying of *latifundia* with their necessary evictions, and by the rapid disappearance from nearly all Italy of her substantial freeholders. Life and property, already widely forfeited at his bidding, were still further endangered by brigandage, which culminated in the formidable rising of Spartacus, who held out for two years (73-71). Still fortifying the senate, Sulla left the tribunes with no power of interdict save in protecting individual plebeians, and he excluded them from ever holding high office; he took from the equestrians the control of the courts, giving it back to the senate, to which he also restored its exclusive rights in the colleges of pontiffs and augurs. He extended the application of the criminal law—a wise measure; but he did more than any Roman before him to facilitate the rise to supreme power of any ambitious governor of a province or leader of a provincial army. He forged in fact the weapon by which his system fell (70).

In Spain Cneius Pompey, one of Sulla's favourites, held a commission from the senate to crush the Marian governor Sertorius, who had defeated successive proconsuls sent to humble him. With the submission of the natives following the murder of Sertorius he returned to Rome, and found the opposition to Sulla looking out for a leader to effect a change of government. His ambition to have a triumph, to be made consul for next year (70), and by consequence to receive command in the east, was gratified for the sake of his name and influence. He was elected consul with Crassus, the victor over Spartacus, their troops being just outside the gates, and on the triumph and ovation granted to the two generals ensued Pompey's fulfilment of the bargain—the reinstatement of the tribunes in their authority and of the equestrians in the courts, and the weeding out from the senate of Sulla's notorious tools. The example set by Sulla was improved upon, and henceforth the republican constitution was at the mercy of the strongest leader supported by the strongest battalions. Pompey's next move was to obtain command abroad, and after some delay this was found in a mission to clear the Mediterranean of pirates. For this formidable undertaking the tribune Gabinius secured him large powers, tenable for three years, including authority over all Roman magistracies in the Mediterranean provinces for fifty miles inland. These, backed by a splendid fleet and army, were yet further enhanced by the tribune Manilius, who got Pompey entrusted with the campaign against Mithridates and with the charge of Roman interests in the east. The wiser senators gave ominous warning against these measures, but were powerless against tribunes and people, seconded by equestrians, who as the commercial class drew much of their wealth from Asia. So Pompey set out in 67. Meanwhile Caesar had come to the front—a patrician, who was also the nephew of Marius and son-in-law of Cinna, and whose consummate ability, shown in the revindication of the tribunate and the carrying of the measures in support of Pompey, had full scope now that Pompey's back was turned. He deepened his hold on the people by avenging the injured names of Marius, Cinna, and Saturninus, pleading for the children of the proscribed, and bringing Sulla's headsmen to justice.

Rising in popular favour by his efforts to enfranchise the Transpadane Latins and his magnificent promotion of public works and entertainments, he spared no means, constitutional or the reverse, to put himself on even terms with Pompey before that magnate's return. Crassus, the millionaire, he found a tractable auxiliary, in

concert with whom he was rapidly gaining powers hardly inferior to Pompey's, when the Catilinarian conspiracy (63), exposed and defeated by Cicero as consul, involved Caesar in the ill-will in which the middle classes held popular adventurers. Pompey had now returned to importune the senate for the ratification of his measures in Asia and the bestowal of land on his legionaries. His demands met with determined opposition, till Caesar, posing as his friend, formed with him and Crassus the coalition—the first, if irregular, triumvirate—of which Pompey was the head, Caesar engaging to see Pompey satisfied, and Pompey in return promoting Caesar's candidature for the consulship. Cicero strove to undo a coalition he knew to be fatal to his ideal of a conservative republic, but in vain; he saw the senate weakened by a quarrel with the equestrians and its authority impugned by the friends of Catiline, who arraigned him for having, with the senate's approval, violated the law in putting to death the conspirator's lieutenants. The triumvirate in 59 fulfilled its compact. Caesar obtained the consulship and the satisfaction of Pompey's demands, conciliated the equestrians at the expense of the senate, and carried an agrarian law enabling him one day to reward his faithful troops. But his crowning success was his obtaining for five years the military command of Cisalpine Gaul, Illyricum, and later of Transalpine Gaul, from which he could scan every political move in Italy. Next year (58) Clodius, the tribune, proceeded against Cicero, who, thrown over by Pompey and with Caesar out of reach, fled from Rome and was outlawed—to be recalled (57), and his outlawry annulled by senate and people, in the reaction induced by Clodius's misdeeds. Cicero renewed his efforts to fortify the constitution, only to fail and retire from public life. The triumvirs tightened their alliance. Caesar secured his command for five years more; Pompey and Crassus were elected consuls, and Pompey received as province the two Spains, with Africa, and Crassus, Syria—the Roman empire being at the mercy of all three, not, however, for long. Crassus was defeated and killed by the Parthians (53), and Pompey was slowly but surely drawn into antagonism with Caesar. Rome, in the absence of efficient government, was in ceaseless turmoil, till the senate in despair induced Pompey to remain in Italy, electing him sole consul (52), giving him, with fresh legions, five years' more command, and, in fact, pitting him as its champion against Caesar. It tried to reduce Caesar to impotence, either by keeping him at his post, and so baulking his candidature for the consulship, which required his presence in the capital, or, by terminating his command at its legal expiry, to detach him from his troops and make him pursue his candidature in Rome as a private individual. Negotiations between him and the senate only left the latter more uncompromising; and with well-inspired audacity he crossed the Rubicon (49) and advanced on the city. Unprepared for such a move, Pompey and most of the senatorial party, including the consuls and many nobles, withdrew to Greece, leaving Caesar to enter Rome in triumph. The mighty duel between the two chiefs had begun. After a brief pause Caesar hurried to Spain, and, victorious over the powerful armies of Pompey's legates, returned to Rome, where, appointed dictator in his absence, he almost immediately renounced the post, and as consul for 48 crossed over into Greece and dealt Pompey a crushing blow at Pharsalia. The Pompeian cause struggled on till 45, when it collapsed at Munda, and Caesar was made by the senate dictator for life. Unlike Sulla, he used his power with a clemency, a statesman-like wisdom, and a patriot-

ism that made men almost forgive, if not forget, how he came by it. The roll of his salutary reforms and innovations is indicated elsewhere (see *CÆSAR*); but here our interest centres in the significance of the empire he initiated. That meant the merely nominal retention of the old constitution with its senate, its comitia, its consuls, and its tribunes, under the fiction that the supreme power was held at the people's will. Really it meant an autocracy reaching to the remotest province, resting in the last resort on the military arm—an autocracy whose founder took the title 'imperator,' as expressing his arbitrary and uncontrolled *imperium*, in token of which he appeared with the laurel wreath and the triumphal garb and sceptre. From the senate which he summoned and presided at to the assembly where he carried laws, and the court where he dispensed justice, he was everywhere the chief magistrate. The empire he designed to bequeath was to be bounded by the ocean on the west, by the Rhine and Danube on the north, by the Caucasus and the Euphrates on the east, and by the African desert on the south, and within these limits he wanted to extend the Roman citizenship, and admit their communities to share the government. This scheme of consolidation he did not live to carry out; but he reduced fiscal burdens in the provinces and curbed the authority of their governors.

His assassination, March 15, 44, was followed by an attempt, powerfully aided by Cicero, to win back the old republican constitution; but Caesar's representative, Antony, at the head of seventeen legions, combined with Lepidus and Octavian, just made consul, in spite of his youth, to form the second triumvirate, which began operations by proscribing and assassinating its opponents—Cicero among the number. A stand made at Philippi by Brutus and Cassius was crushed by Octavian and Antony, and the last hope of the Republican party was gone. The triumvirs divided the empire between them—Octavian taking Italy and the west, Antony the east, and Lepidus Africa. Antony contemplated with Cleopatra an eastern empire, while Lepidus, having lost Africa, was exiled, and the death of Sextus Pompeius, after the destruction of his fleet in the Mediterranean, left Octavian, who had been sagaciously strengthening his position in the west, with only Antony for rival. The inevitable collision took place off Actium (31), and the victorious Octavian, after the suicide of Cleopatra and her paramour, remained master of the east (29). Two years more saw him in Rome, the grand-nephew and heir of Caesar, armed with authority to mould a government out of republican and imperial institutions. For this he had every qualification.

The Empire.—Augustus began (28–27 B.C.) by a restoration of the republic, with himself as *princeps*, the republican constitution being retained, while the *princeps* held the real power. By decrees of the senate he assumed, in token of supreme dignity, the cognomen 'Augustus,' and also the *proconsulare imperium*, which far exceeded the old proconsular command in width of area and length of tenure, the greater part of the provinces being governed by legates appointed and controlled by him alone. Of army and navy he was commander-in-chief, raising or dissolving both, and declaring or concluding war at pleasure. His *imperium*, contrary to precedent, he was allowed to retain within the *pomerium*, the city's consecrated boundary, giving him there the power wielded by a proconsul in his province. Augustus refrained from exercising this in Rome, but as tribune of the people he controlled the entire administrative machine, so that, what with proconsular command and the *tribunicia potestas*, he possessed powers which made all others of

minor importance. Head of the state, he was also head of religion as *pontifex maximus*, and from time to time he had privileges and exemptions decreed him by the senate. Anxious as he was to retain the outward show of republican institutions, they declined under the weight of his personal influence. The comitia were 'transferred from the Campus to the senate,' which in the succeeding reign nominated and voted for candidates to all magistracies except the consulship, these magistracies being in request for the social distinction they carried, not for any power they conferred. The emperor as *princeps* virtually appointed them, and his subordinates transacted their work. The consulship itself, the highest ambition of the private citizen, and a prerequisite for provincial command, was shorn of its duties, excepting those of presiding in the senate and regulating its proceedings. Praetor, aedile, tribune ceased to be what they were under the republic—the last named swallowed up in the *tribunicia potestas*. Only the quaestor retained something of the old significance. But the senate, in theory at least, continued to represent the republican system. To it, in the absence of a princeps, the real power reverted, and from it the new princeps received the authority and the privileges still derived by a fiction only from the people. But the princeps was really nominated by the army, and though the senate was formally deferred to as beyond his jurisdiction, he could in his capacity as censor man it as he chose, till it survived but in name, like the comitia and the magistracies. These innovations had their compensating side. The provinces, previously at the mercy of nominees of the Roman people, now under the control of the princeps or emperor, gradually gained equality with the Italians as Roman citizens, and made corresponding advances in civilisation and prosperity, though reform was naturally slower in those which still remained under the control of the consuls and the senate.

With the establishment of the imperial system the fortunes of Rome are reflected in those of her emperors, to narrate which would be to repeat the biographies given elsewhere. Henceforth we have but to deal with epoch-making events. Tiberius (14–37 A.D.), a capable ruler, more popular in the empire at large than among the aristocracy of the capital, had little of his predecessor's esteem, genuine or assumed, for republican institutions. The senate became more of an imperial tool, all power more and more embodied in the princeps. The simple mode of life affected by Augustus was replaced by a splendour conspicuous in multiplying palatial residences, in the bodyguards, the courtiers, the ætlic etiquette subsequently carried to unheard-of lengths. The population of Rome, from the highest to the humblest, deteriorated—a wealthy, indolent, luxurious upper class maintaining mobs of dependents, below whom was the proletariat, which the emperor from time to time provisioned and amused. Secure against public opinion, Tiberius relied on the military arm, and in Rome himself had his praetorian guard, some 6000 strong, within ready call. These troops acquired a power which overshadowed all others as the emperors became more and more dependent on them. Caligula (37–41), after posing as a liberal ruler, behaved like a madman. After his assassination the praetorians placed his uncle Claudius on the throne (41–54). He was not unstatesman-like, but was ungainly and pedantic, much under the influence of his wives Messalina and Agrippina, and of his Greek freedmen, who wielded a power which soon developed into a central imperial administration. He was succeeded by Agrippina's son Nero (54–68), who was only sixteen, and for the first five years of his reign ruled well under the guidance of Seneca.

But after this things went from bad to worse, and by his suicide he only forestalled his executioners. His vices, however, like those of Caligula, had surprisingly little effect on the empire at large. Like his two predecessors he had first been hailed by the soldiers as imperator, and thereafter invested with power by the senate; but with him the succession from Augustus expired; and whom to replace him by was the question. Galba (68), the nominee of senate and soldiers alike, incurred the enmity of the praetorians, who killed him in the interests of Otho (69), now proclaimed emperor. But the legions on the German frontier preferred their own general, Vitellius (69). Otho, defeated at the head of his praetorians, committed suicide, and Vitellius succeeded him, in turn to be murdered after being disavowed by the army in Syria, who proclaimed their commander, Vespasian. With him began the Flavians (69-96), strong and beneficent emperors, save one. Vespasian (69-79) disclaimed the divine attributes associated with the Caesar-worship of his Julian predecessors, restored a great part of the site of the Golden House to the public by erecting the Colosseum (p. 765), and not only returned to the simpler life and more modest court of early imperial days, but tried to resuscitate the authority of the senate, and even ostentatiously to keep himself within the law and to promote the welfare of the people. His elder son Titus (79-81) improved on this sound policy, but his brother Domitian (81-96) though his reign was a time of great and not unsuccessful military activity (he was responsible for the famous *Limes* in Germany), became infamous for autocracy and cruelty. It is, however, difficult to judge him fairly between the flatteries of the court poets and the bitter invectives of the senatorial party, written at a safe distance of time after his death. Nerva (96-98) was mild, and even weak. His reign soon ended—not, however, before he had adopted as son and successor Trajan (98-117), commanding on the Rhine. From this time on, as far as Caracalla, the emperors employed the fiction of hereditary descent. The assumption of empire by a born provincial illustrates the gradual weakening of Rome's connection with her rulers, whose seat of government became really the military headquarters for the time being. He and the following three emperors gave Rome a century of beneficent rule—the happiest hundred years yet known to her. Living like a plain soldier, he conciliated the senate by the deference he paid it, and the people, whose good he consulted, while keeping the Roman name respected abroad. He adopted a forward policy in the east, which was not followed by his adopted successor, Hadrian (117-138), who gave up to travel the time spent by Trajan in war, visiting the provinces from the east to Britain, providing them with public buildings, improving the discipline of the army and indeed the whole administrative organisation. A provincial himself, he adopted a provincial to succeed him—Aurelius Antoninus, a native of Gaul (138-161). He too earned the love of the Roman world, and on his death an adopted son of his, Marcus Aurelius, became emperor (161-180). He was a thinker and moralist, whom necessity made also a man of action, called away to defend the Danube and Upper Rhine. Unhappy in his wife, he was still more so in his son Commodus, and died at headquarters, closing the line of the good emperors. The profligate reign of Commodus (182-192) accentuated still more the ascendancy of the soldiers, who killed his upright and austere successor, Pertinax (193), and became for nearly a century the makers and unmakers of emperors. The Augustan system was gone; except on a few insignificant occasions, the senate did not assert its

right to nominate; the soldiers, often serving on the frontiers, were the arbiters of empire. The praetorians next sold it to the highest bidder, the rich senator Didius Julianus; but this was resented by the provincial armies, who started their own nominees.

The ensuing conflicts between these 'pretenders' resulted in the triumph of Septimius Severus (193-211), an able, unscrupulous African soldier, who, ignoring the senate, till then the formal ratifiers of imperial authority, set the further precedent of posing as proconsul in the city itself, made the palace, not the forum, the justice-seat, and raised the prefect of the praetorians to power only inferior to his own. Caracalla (211-217), that he might impose on the provinces the taxes paid by Rome, gave the rights of citizenship to the former, thus equalising all and unifying the empire. His brutal personality has no further interest for us any more than that of his fifteen successors, nearly all of whom came by a violent death, generally at the hands of the soldiers who had set them up. See the articles on Heliogabalus, Alexander Severus, the three Gordians, Decius, Gallus, and Gallienus. They left the Roman empire weak at every frontier, exposed to the Franks on the Rhine and the Goths on the Danube. The former ravaged Gaul and Spain, the latter Asia Minor and Greece, while the Persians, relieved of the Parthian yoke, had again become a formidable power in the east. In Rome and throughout Italy anarchy and distress prevailed till a temporary revival was brought about by the *Illyrian emperors*—Claudius (268-270) driving back the Goths, and the yet abler Aurelian (270-275), by his victories over Goths and Germans and his successes in the east and west, restoring the lustre of the Roman arms, and, for a brief space, the unity of the empire.

Diocletian (284-305), also an Illyrian, the next great name on the imperial roll, introduced a system of safeguards against dissolution within and aggression from without. He assumed the most capable colleague he could find to share with him the government of the empire. This was Maximian, who, like himself, took the title of Augustus. He further reinforced this dual control by associating with him Galerius and Constantius, able generals, like Maximian, whom he proclaimed as *Cæsares*, below the two *Augusti* in rank, but with the right of succession to these. He himself had Thrace, Egypt, and Asia under him; to Maximian he gave Italy and Africa, to Constantius Gaul, Spain, and Britain, to Galerius the Danubian provinces. Thus internal sedition was suppressed within the empire, and, this distraction removed, the frontier fortifications could be perfected. The Rhine, the Danube, and the Persian boundary were garrisoned at frequent intervals and the barbarians kept in check, while all temptation of the soldiers to sedition was overawed by the repressive measures at the command of the four rulers acting in concert. Rome now ceased to be the one capital. If she remained a capital, it was as the seat of a nominal senate. The *Augusti* and *Cæsares* lived at their headquarters, Diocletian at Nicomedia, Maximian at Milan, Constantius at Treves, Galerius at Sirmium. This was a momentous departure from the tradition by which the emperors had claimed to be but the supreme magistrates of the city and the chiefs of her armies. Rome indeed was less imperial than any town in which the emperor chose to live. The policy of keeping the soldiery estranged from the emperor's presence took the form of increased dignity in his demeanour and mode of life, the oriental magnificence introduced by Aurelian reaching extravagant lengths in Diocletian. He reorganised the services, civil and military, under new titles, which came to be more

valued than the republican consul or senator, and typified the completely autocratic power he assumed. So long as he lived his system worked effectively; but after twenty-one years, and in breaking health, he abdicated publicly the power he felt incapable of wielding. His masterful personality no longer felt, rupture between *Cæsares* and *Augusti* ended in civil wars, till the son of the Cæsar Constantius, Constantine, who had himself become Cæsar of the army in Britain, overcame all rivalry, and in 323 ruled the empire single-handed. Christianity, since its rise under Augustus and its spread under Tiberius and the later emperors, had triumphed over the last attempt under Diocletian to crush it by persecution, and the politic Constantine, adopting it as his own religion, made it also the state's. To the tottering imperial fabric it brought new strength, armed with which he proceeded to develop Diocletian's policy of rehabilitation. From Rome he transferred the seat of government to Byzantium, henceforth called Constantinople, commanding by its position the Greek and Asiatic worlds. Remodelling Rome's traditional institutions, he made a new senate, with a large infusion of Greeks, all of his own choosing; he instituted a new *præfectus urbi*, and founded in the 'Rome on the Bosphorus' an absolute monarchy. Reducing the number of soldiers under each general, he weakened the army's power to revolt by dividing it into two classes, one for the towns, the other for the frontiers. The same subdividing process he carried into the provinces, splitting them up into districts, which again he rearranged into thirteen larger ones, subject to four prefects, responsible in their turn to the emperor. Multiplying officials who owed everything to him, he made them the nucleus of a new nobility, to supersede the old, and to find their interest in perpetuating his power. These sagacious measures, coupled with the prestige of the new religion, reinforced the empire greatly; but the taxation required to keep it up proved an element of weakness. The costly court and the highly paid officials drained the treasury, which had to be replenished by exactions from the people, who met them from the proceeds of the land they tilled. The forays of barbarians, increasing in number and range, steadily reduced the means of these small holders, who thus, except in profound peace, could not satisfy the tax-gatherers. Farms disappeared, not to be replaced, and unproductive waste-lands encroached more and more within the frontier. The death of Constantine was the signal for civil war among the rival Cæsars, till Constantine's only surviving son, Constantius II. (351-363), succeeded in reuniting the empire under the same house. Not without misgiving he made a 'Cæsar' of his cousin Julian and entrusted him with Gaul, where Julian's success was such as to rouse his jealousy. Constantius accordingly commanded his cousin's legions to start for Persia; but instead of complying they proclaimed Julian emperor and Augustus. Constantius died soon after, and an inevitable collision was averted. Julian (361-363) interests us more by his defence of the Rhine frontier and his Persian campaign than by his 'apostasy' from Christianity. He succeeded in staving off the barbarian inroads on the western provinces; but his diversion in favour of the 'creed outworn' did not survive his last encounter on the Tigris, where he was killed. Jovian, who succeeded him on the battlefield, outlived him a few months, and Valentinian I. (364-375), the next emperor, at the instance of the army which proclaimed him, took as colleague his brother Valens, whom he made emperor of the east. For ten years the dual government prevailed, and the barbarians were kept in check at the Rhine and

Danube, but his death found Valens unequal to his post. The Goths, goaded by the Huns in their rear, had thrown themselves on the hospitality of their imperial neighbours, but were so harshly treated that they turned on them and killed Valens in battle (378). They threatened Constantinople, but the next emperor, Theodosius (379-395), made them his allies and even auxiliaries, so that he was able to keep on the throne his colleague of the west, the feeble Gratian. That emperor was murdered (383) by Maximus, whom Theodosius recognised as Cæsar and left in command of Gaul, Spain, and Britain, till he attempted to oust Valentinian II. from Italy and Africa, when he was crushed by Theodosius (386-391). A few months afterwards Valentinian was murdered by Arbogast the Frank, who nominated in his place a creature of his own, Eugenius. Again Theodosius triumphed over the usurper; but after his great victory at Aquileia he died (395), leaving as emperors his two sons—Arcadius in the east and Honorius in the west.

The next eighty years are amongst the most dismal in the world's history. The provinces, drained to inanition by taxation levied for army and court, were further visited by intestine war and barbarian inroads. At first the policy of conciliating the invader, and giving him military command and administrative office, succeeded. But gradually the barbarians established in the east began to aim at conquest in the west, and Alaric the Goth first occupied Illyricum, whence he ravaged Greece, to be driven out by the Vandal Stilicho, the able general of Honorius. Retaining Illyricum, he led his people *en masse* into Italy; but after his crushing defeat at Pollentia he again retreated before Stilicho. On the murder of that officer he returned and besieged and took Rome, which bought him out at a heavy price. Honorius, from his seat at Ravenna, could not be made to concede him the lands he wanted for his people and the post in the imperial army he claimed for himself, so Alaric again appeared before Rome, to accept the office of commander-in-chief under her improvised 'Augustus,' the prefect Attalus. This incapable ruler was displaced by Alaric, who resumed his negotiations with Honorius. These being again fruitless, he took and sacked the city, but died shortly after. His successor Ataulf drew off his people to Gaul, and (419) a succeeding king, Wallia, received formal permission from Honorius to settle in the south-west, where at Toulouse he founded the Visigothic dynasty. Spain, already divided between Vandals, Sueves, and Alans, was in like manner formally made over to those invaders by Honorius, whose authority at his death (423) was on the western continent merely nominal.¹ His successor, Valentinian III. (423-455), witnessed the conquest of Africa by the Vandals and of Gaul and Italy by the Huns. The former, under Genseric, having taken Carthage, were recognised by Valentinian in their new African kingdom in 440; and the latter, the rulers, under Attila, of central and northern Europe, confronted the emperors of east and west alike as an independent power. Attila marched first on Gaul, but the Visigoths, since their conciliation by Honorius, were loyal enough to oppose him, and, commanded by Aetius, signally defeated the Huns at Châlons (451). Next year Attila invaded Lombardy, but got no further, and died (453). In that year Valentinian, the last representative of the house of Theodosius in the west, was murdered; but

¹ There has recently been some discussion as to whether Britain ceased to be Roman in 407 or 442 A.D. In either case the step was not a formal nor deliberate abandonment, but was due to the need of troops elsewhere.

his nine successors have no claim on our attention here. The outstanding events in the history of Rome are now her siege and sack by Genseric (455), and the quarrel between the Emperor Orestes (a Pannonian) and the barbarian soldiery in Italy—the latter requesting and the former refusing a grant of a third of the lands. The soldiery defeated and killed Orestes, whose son Romulus Augustulus resigned the 'useless purple' in favour of their leader Odoacer (476). The empire of the west was gone, Italy was under a barbarian king, and Rome ceased to be the capital. Thenceforth the history of Rome is merged in that of Italy (q.v.), where will be found such outstanding events as the restoration to the city, or to the pope, of the lands rescued by Pepin (q.v.) from the Lombards, the taking of Rome in 1084 by the Emperor Henry IV., the short rule of Rienzi (q.v.), the sack in 1547 by the Constable de Bourbon (q.v.), the Napoleonic invasion of 1796, the republic of 1849, and the re-establishment in 1870 of Rome as capital of Italy. The history of the Eastern Empire is given at BYZANTINE EMPIRE.

See Mommsen, *History of Rome* (Eng. trans. 1894) and *Provinces of the Roman Empire* (1886; fourth German edition, 1894); Pais, *Storia Critica di Roma* (1913-21), *Ricerche Storiche* (1915-21), *Storia dell'Italia Antica* (1925 et seq.); De Sanctis, *Storia di Roma* (1907 et seq.); Heitland, *Roman Republic* (1909); Pelham, *Outlines of Roman History* (1893); Stuart Jones, *Roman Empire* (1908), and the article by Pelham (revised by Stuart Jones) in the *Encyclopædia Britannica*. A history of the Roman Empire (a great desideratum) has been begun by Dessau, *Geschichte der römischen Kaiserzeit* (vol. i., 1921, deals with Augustus). For the later Empire, see Gibbon's *Decline and Fall of the Roman Empire*, ed. Bury (1892-1900); Bury, *The Later Roman Empire* (1923); Hodgkin, *Italy and her Invaders* (1880-85).

RELIGION.—The development of a small city-state into a great empire comprising many different races, languages, and civilisations makes the problem of the Roman religion a complicated one. Among Latins, Sabines, Etruscans religion took an Italian development, redolent of their racial and local characteristics, of which, as compared with the Greeks, lack of creative power

the Roman divine world that wealth of legend which makes the Greek so picturesque, while from the same cause the Roman divinities betray fewer of the failings by which those of Greece often sink to the human level. The Roman genius, with its practical and objective turn, determined the more observant spirit of its religious worship, which in its minute attention to detail, both in word and act, implied a graver, more reverential notion of deity. Sprung from shepherds and husbandmen of the simplest patriarchal type, the early Romans strike a rural and domestic note in their religion, worshipping especially the gods of nature, of field and forest, the bounteous protectors of flocks, or donors of harvests, like Fannus, Vertumnus, Saturn, Ops, and the gods who shielded the house and its inmates, gods of the family (Lares and Penates). This worship long retained in Rome the rural and household traits of its original inspiration, and far down in the history of the empire we find numerous festivities antique as to observance and yearly as to recurrence, in the Saturnalia, Lupercalia, and such like. These agricultural, pastoral, and household divinities, however, were only 'numina,' spirits with specialised functions but without human attributes; it was only with Rome's political growth as an Italian power that a mythology began to be created, and state-deities like Jupiter came to the front. After Jupiter, the head of the divine world, came Mars, the defender of the city, father of Romulus and of the Roman people, and Quirinus, the deified Romulus. A second Rome-defending

trinity was composed of Jupiter, with his sister and consort Juno and his daughter Minerva. Beside them in reverential honour were worshipped Vesta, goddess of the sacred fire and of the household hearth, and Diana, goddess of the moon. The deities just enumerated, especially the protective or tutelary deities, formed the main body of the state-religion of the Romans—a state-religion of which their second king, the Sabine Numa, was the revered founder and organiser. Of subordinate importance, but closely intertwined with public life and its concerns, came the worship of abstract, chiefly moral entities, embodied in the religious conception as Virtus, Fides, Pietas. Such deities gradually multiplied according to the appreciation or whim of individuals, till nearly every possible condition or influence, including the commonest occurrences and agencies, even accidental phenomena, were endowed with divine being, and worshipped accordingly. So we find Orbona, the averter of bereavement and bringer of comfort to its victims; Fessonia, the preserver from weariness; Quies, Felis, Abeona and Adeona (the goddesses invoked on departure and arrival). The natural world, the civic, the moral—the three elements above indicated—were the chief components of Rome's religion, and during her supremacy constituted a trine whole jealously guarded by the state from every foreign contamination. But with the spread of her dominion, particularly on her coming into closer contact with the Greeks in lower Italy, she imported into her religion extraneous, mostly Greek, objects and modes of worship. She came early to revere the oracular Apollo of Delphi, and (432) erected in Rome a temple in his honour as the plague-averting deity. Castor and Pollux were another acclimatisation, and her temple to them dates from 304. Venus was introduced, while the worship of Esculapius was taken from Epidaurus (291). So long as her civilisation continued national Rome kept this foreign cult, though introduced and sanctioned by the state, as something separate from her old constitutional religion, which was thus maintained free from all corrupting or disintegrating infusion. Subsequently to the second Punic war, however—that turning-point in her civilisation—in an incredibly short time she became penetrated by Greek and oriental influences, and opened the door to the mythological traditions of Greece. She did indeed retain, for the most part, the names she had given her gods and the rites by which she worshipped them; but these were gradually undermined and overspread by Greek notions, until her literature, in so far as it dealt with religion, became impregnated with Greek legend and spirit. Nor was it Greece at her best that Rome followed in this subjection to her influence. Greece had long panted with her better traditions, and could convey little but what was sceptical and frivolous of her own or what was superstitious and fleshly of her eastern neighbours. Asia and Egypt, through the intermediation of Greece, and latterly at first hand, became the source of a sombre, sensual, degrading cult, which Rome, professedly at least attached to her healthier, more masculine worship, strove fruitlessly to counter-veil. Augustus did his best to prop up the declining religion through restoration of old usages and festivals, the rebuilding of temples on a more magnificent scale, and the discouragement of superstitious importations. Ovid made himself the poet of a similar inspiration in his *Fasts*, wherein he tried, by revivifying the old forgotten ceremonies, to reawaken the spirit from which these had sprung. This revival of religion together with emperor-worship had, however, also a political motive behind it. Later emperors interposed from time to time in the same cause; but in vain. Religion and

morals deteriorated with a rapidity that helps to explain the steady, irresistible advance of that religion of which Rome became the seat.

See the chapters on Roman religion in the standard histories of Mommsen, Marquardt, Boissier, &c., the references in Frazer's *Golden Bough*, and the articles in Pauly-Wissowa, *Realencyclopädie der klassischen Altertumswissenschaft*. Rome, (1) capital of Floyd county, Georgia, on the Coosa River, 72 miles by rail NW. of Atlanta. It has iron-foundries, brick-yards, manufactories of ploughs, &c., and ships cotton. Pop. 13,000. — (2) A city of New York, on the Mohawk River, 169 miles by rail WNW. of Albany, and at the junction of the Erie and Black River canals. The chief industries are manufactures of machinery, iron, brass, copper, and other goods. Here is Fort Stanwix, which was successfully defended against St Leger, and 6 miles to the south-east the battle of Oriskany was fought during the Revolution. Pop. 26,000.

Rome, PRIX DE, the great prize given by the École des Beaux Arts and the Conservatoire in Paris, consists of a certain sum for four years, during which the recipient is expected to study painting or music at Rome. Brussels Conservatoire also awards a Prix de Rome for music.

Rome-scot, a name for Peter's pence (q.v.).

Romford, a market-town of Essex, on the Bonnie or Rom, 12 miles ENE. of London. It has great cattle and corn markets, iron-foundries, and market-gardens, and a very large brewery of 'Romford ale.' The church of St Edward the Confessor was rebuilt in 1850. Romford is the capital of the Liberty of Havering-atte-Bower, once part of the lands of the Saxon kings. Pop. of urban district, 20,000.

Romilly, SIR SAMUEL, English lawyer and law reformer, was born son of a watchmaker of Huguenot descent at London, 1st March 1757. At sixteen he was articled to one of the Chancery clerks, at twenty-one entered himself at Gray's Inn, and afterwards went the Midland Circuit, but found his chief employment in Chancery practice. In 1784 he made the acquaintance of Mrabeau, who introduced him to Lord Lansdowne; in 1790 he published an able pamphlet on the French Revolution. In 1806 he was, at Fox's instance, appointed Solicitor-general in the Grenville administration, and was compelled to accept the honour of knighthood. He took his seat for Queenborough, as in

later parliaments for Horsham, Wareham, and Arundel. He now devoted himself, by pamphlet and parliamentary agitation, to mitigate the severity of the criminal law, which at that time inflicted Capital Punishment (q.v.) on over 200 different offences. His bills were session after session rejected, but Romilly nevertheless persevered, and, if he saw little fruit of his labours in his lifetime, made his name famous over Europe. He took an active part in the anti-slavery agitation, and in opposing the suspension of the Habeas Corpus Act, the spy system, and the despotic acts of the government. In July 1818 he was spontaneously chosen by the electors of Westminster as their representative. His wife died on the 29th October of that same year, and the shock so preyed upon his mind that three days after (November 2, 1818) he put an end to his life. See his *Speeches in Parliament* (2 vols. 1820), and his *Autobiography* (3 vols. 1840).—His second son, JOHN, BARON ROMILLY, born in 1802, was educated at Trinity College, Cambridge, and called to the bar at Gray's Inn in 1827. He was made Solicitor-general in 1848, Attorney-general in 1850, Master of the Rolls in 1851, and created a Baron in 1866. As Master of the Rolls Romilly incidentally rendered great services to his country, by superintending the publication of public records tending to throw much light upon English history and events. He died on December 23, 1874.

Romney, NEW, a municipal borough and Cinque Port in the south of Kent, 8 miles SW. of Hythe. It ceased to be a port in the days of Edward, and is not now either on the seashore or on a navigable river. Pop. (1881) 1007; (1921) 1605. Old Romney, a small village, is 1½ mile further inland. New Romney is the capital of the Romney Marsh district of fertile pastures, has a great sheep fair, and is connected with Lydd by a railway line 3 miles long. Of its five churches only one (St Nicholas) remains.

Romney, GEORGE, painter, was born at Beckside, near Dalton-in-Furness, Lancashire, on 26th December 1734. He was the second in a family of ten sons and one daughter, his father a clever carpenter and cabinet-maker; and after a very brief schooling he worked for ten years at his father's trade. Meanwhile he saw much of one Williamson, a watchmaker, philosopher, and alchemist; and meanwhile also he carved wood and drew. In 1755 he was articled to a 'Count' Steele at Kendal to be taught 'the art or science of a painter'; in 1756 married Mary Abbot of Kirkcaldy; in 1757 set up as a portrait-painter on his own account; and in 1762 came up to London alone, leaving behind wife, boy, and baby girl—the last died a twelvemonth after. Of Romney's next thirty-seven years there is little to record, beyond his two visits to France (1764; 1790) and his two years' residence in Italy (1773-75), after which, for twenty-two years, he lived in Cavendish Square. He slaved at his art, and his art so far rewarded him that Lord Thurlow said, 'Reynolds and Romney divide the Town: I am of the Romney faction,' and that in the single year 1786 he made by portrait-painting 3500 guineas. Of all his sitters he most celebrated is Lady Hamilton (q.v.), the 'divine lady,' so Romney called her. He painted her as 'St Cecilia,' as 'Joan of Arc,' as 'A Magdalene,' as 'A Bacchante,' and in some thirty other characters. This Lady Hamilton series, Miss Sneyd as 'Serena' and 'The Parson's Daughter,' are probably his masterpieces. Romney was not an intellectual painter, suffering, too, from the lack of a sound early training, but his best portraits make an inevitable appeal, because of their natural freshness and sympathy. They are full

of charm, with the most delicate flesh-tints and colouring of draperies. About 1791 his health began to give way. His habitual sensitiveness and reserve developed into deep melancholy, and this with a corresponding weakening of his physical powers caused his art rapidly to deteriorate. In 1799 he returned to Kendal to die there on 15th November 1802. *Finis!* No; the true *finis* is given by Edward Fitzgerald: 'How touching is the close of Romney's life. He married at twenty-one, and, because Sir Joshua and others had said that marriage spoilt an artist, almost immediately left his wife in the north, and saw her but twice till the end of his life, when old, nearly mad, and quite desolate, he went back to her, and she received him, and nursed him till he died. This quiet act of hers is worth all Romney's pictures.'

See Laves of the painter by his friend Hayley (1809) and by his son, the Rev. John Romney (1830); Lord R. Gower, *Romney and Lawrence* (1882); H. Gaulin, *Romney and his Art* (1894); the study by 'G. Paston' (1903); the large work by T. H. Ward and Roberts, with a catalogue raisonné (1904); Chamberlain, *A Romney Photo* (1911); and R. W. Lloyd, *The Cult of Old Paintings and the Romney Case* (1917).

Romorantin, a town of France (dept. Loir-et-Cher), 45 miles by rail E. of Tours; pop. 8000.

Romsdal, the valley of the impetuous Ranna in central Norway, which reaches the sea half-way between Bergen and Trondhjem. It is celebrated for its magnificent scenery: the mountains rise precipitously to 5000 feet—the Trollinder or Witch Needles are 5880 feet high—the floor of the valley is strewn in places with gigantic blocks from mountain landslips; and cascades dash 3000 feet down the sides of the mountains.

Romsey, a municipal borough of Hampshire, on the Test, 8 miles N.W. of Southampton. The fine cruciform abbey church, mainly Norman, but with Transition, Early English, and Decorated features, was the church once of a Benedictine minster, founded about 907 by Edward the Elder. Sir William Petty was the son of a Romsey clothier; and Lord Palmerston, of whom there is a bronze statue (1868) in the market-place, lived close by at Broadlands. A corn exchange was built in 1865, a town hall in 1866. Pop. 4800.

Romulus, legendary founder and first king of Rome, son by Mars of Rhea Silvia, the daughter of king Numinor of Alba Longa, was along with his twin-brother Remus exposed by their uncle Amulius, who had usurped Numinor's throne, but was suckled by a she-wolf, and brought up by the shepherd Faustulus and his wife Aeca Laurentia. In 753 B.C. he founded his city on the Tiber, slew his brother, and invited for his citizens all homeless fugitives around, who carried off Sabine maidens for their wives. After Romulus had seen the Romans and Sabines united, and firmly established his city, he was carried up to the heavens in a chariot of fire (716 B.C.), and later worshipped as Quirinus.

Romulus Augustulus. See ODOACER; and ITALY.

Ronaldshay. See ORKNEY.

Roncesvalles. See ROLAND.

Roneiglione, a town of Central Italy, 30 miles NNW. of Rome; pop. 6500.

Ronda, a town of Spain, stands on each side of a grand gorge through which flows the Guadizar, and across which two bridges are stretched, one 255 feet from the water, 43 miles W. of Málaga; pop. 30,000.

Rondeau (Fr.), a form of poem characterised by closely-knit rhymes and a refrain, and, as defined in the 17th century, consisting of thirteen

lines, divided into three unequal strophes; the two or three first words of the first line serve as the burden, and recur after the eighth and thirteenth lines. It was brought into vogue by Swinburne.

Rondo (Ital.), the most obvious and elementary form in music, in which the first subject, clearly marked out, followed by a second, more or less definite, recurs again in its original key. In later developments the repetition may take place twice, thrice, or even four times, sometimes in part only, or in modified form, the intervening sections being varied in different ways. A large proportion of songs and instrumental pieces are in this form; and the final movement of a sonata, symphony, or concerto is frequently a rondo.

Ronge, JOHANN. See GERMAN CATHOLICS.

Ronsard, PIERRE DE, French poet, was born of good family at the Château de la Poissonnière, in Vendôme, in September 1524 (there exists some doubt about the actual date). Except for six months at the Collège de Navarre, he remained at home till his twelfth year, when he entered the service as page, first of the Dauphin François (who died August 1536), and second of the Duc d'Orléans, second son of the king, François I. In 1537 Ronsard accompanied to Scotland Madeleine, daughter of the French king and bride of James V. She died shortly after, but Ronsard remained in Scotland over two years, and after being six months in England returned to France to re-enter the service of the duke. Ronsard's youth was precocious; before he was sixteen he had a fluent knowledge of English, Italian, and German, was an accomplished diplomat, and had been sent to Flanders, again to Scotland (being shipwrecked on the way), and to Strasburg, part of the time with the cultured ambassador, Lazare de Baif. But his career was cut short by deafness, the result of an illness, whereupon he determined to abandon arms for letters. About 1541 he repaired to the Collège de Coqueret, then under Daurat, the 'dark star' of the famous *Pléiade* (see *PLÉIADES*). Here also studied at the same time three others of the seven, Baif (a kinsman of the ambassador), Belleau, and Joachim du Bellay (q.v.). The *Défence et Illustration de la Langue Française*, written by the last, appeared in 1549, the manifesto of the movement—a revolution in French poetry. Ronsard's period of study lasted till 1550, when he published the four books of his *Odes*, the best practical illustration of the *Pléiade* doctrines that humanity is worth studying in all its phases, and that beauty is to be appreciated just for its own sake. The members of the *Pléiade*, led by Ronsard, were true followers of the Renaissance; though they had diligently studied the Latin and Greek poets (especially Anacreon and Pindar), they resolved, first, to make the vernacular tongue, and not Latin, the ordinary accepted means of artistic expression, and, second, to allow any subject, however lowly, to be sublimated into something of æsthetic value. This necessitated a great increase of vocabulary, for appropriate language must always be used to express the thought; a simple subject must not be overloaded with conventional epithets, but the machinery of mythology was not to be discarded if the occasion demanded it. It was this 'corruption' of vocabulary, the free use of 'unlawful' rhymes, of diminutives, of colloquialisms, the use of the same language for poetry and for prose, that roused the opposition of the classicists, begun by Malherbe and continued by Boileau. From 1630 to 1820 no new editions of Ronsard's poetry were published, but the reaction came with Lamartine, de Vigny, and the romantic movement of the 19th century, when the work of the *Pléiade* was appreciated at its full value again.

Fortune favoured Ronsard, however, in his lifetime. The years 1550-60 were the most prolific as regards output. After the *Odes* in 1550 came the *Amours* in 1552; *Le Bocage*, a collection of serious pieces; and *Les Meslanges*, a collection of gayer pieces, in 1554; *La Continuation des Amours* in 1556; and, finally, a complete edition of his works in 1560. Ronsard is a stylist, a master of delicate rhythms; his sonnets and odes have a charm and vitality that fully compensate for any mannerisms of expression or contemporary allusions that tend to 'date' or disparage his work. Ronsard's contemporaries certainly appreciated him, calling him the 'Prince of French poets'; Montaigne admired him, and Spenser and other Elizabethans acknowledged their indebtedness to him. He was a favourite of Marguerite, sister of Henri II., was pensioned both by Henri II. and François II., and received presents from Elizabeth and Mary, Queen of Scots. Before his death there had appeared six complete editions of his works, each edition usually containing a certain amount of new material. Charles IX. heaped further favours on the lucky poet, who after the king's death, feeling the burden of enfeebled health, retired to the abbey of Croix-Val in Vendôme, where he spent most of his remaining years in lettered ease. Ronsard died at the priory of St Cosme at Tours in December 1585.

See RENAISSANCE, and books there cited, dealing with France. Complete editions of Ronsard have been published by Blanchomain (8 vols. 1857-67), Marty-Laveaux (6 vols. 1887-93), Laumonier (8 vols. 1914-19), and Vaganay (1910-24), and numerous volumes of selections have been made by various editors. See Binet, *Vie de Ronsard* (1586; ed. Laumonier, 1910); Sainte-Beuve, *La Poésie Française au seizième siècle* (1828); G. Wyndham, *Ronsard and La Pléiade* (with translations into English, 1906); studies by Laumonier (1909) and Jusseland (1913); P. de Nolhac, *Ronsard et l'Humanisme* (1921); and G. Cohen, *Ronsard* (1924), a re-examination in light of 20th-century scholarship.

Röntgen. WILHELM KONRAD VON, physicist, born 27th March 1845 at Lennep in Rhineland, studied at Zürich, was professor at Strasburg, Giessen, Würzburg, and Munich. He contributed to science on specific heat in gases, elasticity, compressibility, capillarity, the absorption of heat in steam and gases, and especially the X-rays, usually called after him. He died at Munich 10th February 1923.

Röntgen Rays (X-RAYS).—When experimenting upon the passage of an electric current through highly rarefied gases contained in glass tubes, Röntgen in 1895 found that photographic plates placed in the vicinity, though screened from the action of light, were affected as though light had penetrated the opaque envelope which contained them. It was soon observed that the effect was due to a radiation proceeding in straight lines from the glass tube. This previously unknown radiation was called X-radiation or Röntgen radiation. For some years there were differences of opinion regarding its nature; it is, however, now known to consist of electric waves similar to wireless waves and light waves, but of enormously shorter wavelength than either. The differences between the properties of X-radiation and light are differences of degree rather than of kind.

What appeared the most remarkable property was that of penetrating comparatively thick sheets of substance opaque to ordinary light, and even thick sheets of the lighter metals as aluminium. Unlike light, the radiation could not be detected by its direct action upon the eye—it produced no sensation of sight; but it was observed that a number of substances when exposed to the radiation emitted light. These fluorescent substances thus acted as detectors of the invisible X-radiation.

The best known of these is barium platino-cyanide, which glows with a greenish yellow light when exposed to X-rays. Such a substance when spread over a sheet of cardboard forms an X-ray screen.

Though the photographic and fluorescent methods are the most easily applied, a third method known as the ionisation method has proved the most useful from a purely scientific standpoint, for it gives accurate measures of intensity of radiation. Thus when X-rays traverse a gas, such as air, they make the gas into a good conductor of electricity. As a current of electricity can then be passed through the air, the current may be measured and used to give a measure also of the intensity of the X-rays.

X-ray Tubes.—As the radiation proceeded from the portion of the glass tube struck by electrons (the kathode radiation) known to be shot across the tube from the surface of the kathode, the kathode was made cup-shaped, and the electrons were thus focussed to a definite spot on a target of metal—the antikathode. The spot on the antikathode struck by the kathode rays is then the source of the X-radiation. Heavy metals with high melting-points, as platinum and tungsten, are usually employed as targets in which the X-rays are excited, but for special purposes many other metals are used.

In many X-ray tubes the targets are cooled by water circulation and by other devices.

The more modern Coolidge tube is so highly exhausted (10^{-9} atmosphere) that a current cannot be sent through it in the ordinary way. A stream of electrons is provided by electrically heating to incandescence a small coil of wire situated inside the tube. The electrons emitted by this hot wire are directed on to the target by an applied electric field. The number of electrons used to generate the X-rays can then be controlled by varying the current through the coil: thus the intensity of the radiation may be varied. Also the potential applied to the tube can be controlled, and thus the velocity of the electrons when they strike the target. This controls the character—the wavelength—of the radiation emitted.

Very recently metal instead of glass X-ray tubes have been constructed with targets situated very near to the thin metal windows through which the X-rays pass into the space outside. Enormously increased intensity has thus been obtained.

Theory of Excitation.—The radiation emitted by an X-ray tube is a mixture of (a) a *general radiation* of all wave-lengths between wide limits, and (b) a *characteristic radiation* of certain definite wave-lengths, characteristic of the metal of which the target is made. The one gives a continuous spectrum, the other a line spectrum in X-rays of wave-length depending on the particular target.

The constituent radiation of highest frequency n is related to the maximum speed v of the exciting electrons by the equation $hn = \frac{1}{2}mv^2$ when m is the mass of an electron and $h =$ Planck's constant. It is thus as if all the energy of an electron ($\frac{1}{2}mv^2$) was transformed into one quantum of radiation, the quickest electrons producing radiation of highest frequency or shortest wave-length. (See QUANTUM THEORY.)

When a gas-tube (distinguished from a Coolidge tube) is highly exhausted, it requires a large potential difference to send a discharge through it, and the electrons acquire a high speed. Consequently the radiation is of high frequency; it is a highly penetrating or 'hard' radiation, and the tube is described as a 'hard' tube. Softer rays (of longer wave-lengths) are emitted by a tube containing gas at high pressure.

There is strong evidence that the wave motion which constitutes X-radiation is emitted by electrons in vibration near to the central nucleus of an atom (surface electrons in vibration emit light which is of longer wave-length; electrons vibrating in the nucleus emit γ -rays of even shorter wave-lengths than X-rays).

The mechanism by which radiation is emitted is unknown, but by Bohr's theory a characteristic X-radiation is emitted when an electron striking the target knocks an electron from its orbit in an atom, and another electron falls from an outer orbit to take its place. The fall from an outer orbit to an inner orbit necessitates an emission of radiation of frequency n where hn = energy lost by the falling electron. This quantum relationship is still a mystery. It is probable that the general radiation is emitted by the electrons which strike the target during their passage through atoms of the target.

Fundamental Properties of X-rays.—During transmission through material substances an X-radiation loses intensity in two ways: some radiation is scattered by the substance traversed as light is scattered by smoke; some of it is used up in ejecting electrons from atoms. The latter appears to be the only way in which X-radiation can be absorbed, the energy being in some way transferred to these electrons. All the properties of X-rays seem to be fundamentally dependent on this power of ejecting swiftly moving electrons; other actions are secondary actions due to this primary action of the rays themselves. In general, more electrons are ejected from heavy atoms than from the same number of light atoms traversed by the same radiation, the number being approximately proportional to (atomic number)². The maximum velocity of ejection depends not upon the parent substances nor on the intensity of the radiation, but only upon its wave-length, a fact which has received no explanation on the wave-theory. Thus X-ray effects are much greater in heavy elements, and these correspondingly absorb the radiation most strongly. Consequently lead, gold, platinum, &c., and substances containing these are very opaque, while carbon, silicon, aluminium, and other light elements are comparatively transparent. Thus screens used for protection from X-rays are of lead; windows are of paper, cardboard, or aluminium.

Electrons ejected from certain atoms pass through surrounding atoms, detaching other electrons here and there in their path, and they finally settle on other atoms. The total path in atmospheric air of the original ejected electron is of the order of 1 inch and less, but in a rarefied gas the length of path may be increased almost indefinitely. The path of the electrons in the human body is about $\frac{1}{3}$ inch and less. Each high-speed electron thus ionises (electrifies) many atoms around, hence the greatly increased conductivity of the substance traversed by X-rays; hence also the photographic action, and the many chemical actions which are stimulated by this ionised state.

Subsequent to the emission of the high-speed electrons, a vibration in the atom is set up when electrons of the outer orbits fall into the orbit previously occupied by the ejected electron. Thus characteristic X-radiation is emitted by the substance traversed by the X-rays, and in this way any substance may be made to emit its characteristic X-radiations.

X-rays are regularly reflected from a crystal, for in this the atoms are arranged on a system of almost perfect parallel planes. The reflection from each layer of atoms is very faint, but, provided the wave-trains from the parallel layers agree in phase (are in step), all the feebly reflected

trains add their effects, and a strong reflection is produced. This, however, is not surface reflection. The condition for agreement of phase is that $2d \sin \theta = n\lambda$ where d is the distance apart of the crystal planes, θ is the 'glancing angle', λ is the wave-length of the radiation, and n is an integer. Thus, radiation of given wave-length when incident on a certain crystal is reflected only when the angle of incidence has very precise values, as when $\sin \theta = \frac{1, 2, 3, \dots \times \lambda}{2d}$. This important

relation forms the basis of measurements of two kinds—(1) the measurement of wave-length λ when the spacing d of a set of planes in a crystal is known; (2) the measurement of the spacing of the various sets of planes in a crystal when the wave-length is known. Such measurements are usually made by an X-ray spectrometer. The wave-length ranges from about 10^{-8} cms. (very soft rays) to about 3×10^{-8} cms. (very hard rays). From measurements of the second kind the arrangement of the atoms of various kinds in a crystal has in many cases been deduced.

Practical Applications.—Owing to the high penetrating power of X-rays and to the fact that the absorption varies rapidly with the atomic number of a substance, they are very useful for observation of internal structures. Rays are passed through the substance and the luminosity produced on a screen beyond is observed directly, or the effect on a photograph plate is made permanent by developing and fixing. Any lack of homogeneity of the substance is shown by a variation in intensity of the rays transmitted—that is, by shadows cast by the heavier elements. Thus the position of (or fractures in) bones, the position of foreign bodies, the position and size or even any pronounced change in the organs themselves are shown by the shadow density. The position of a foot in a shoe, the sphericity of the core of a golf-ball, faults in castings, and in the fibrous structure of wood, the presence of foreign matter in coal, can all be observed.

X-rays have been found to be beneficial in the treatment of ringworm, rodent ulcer, and possibly in some cases of cancer. The action is doubtless due to chemical action stimulated by the ionisation produced in the diseased tissues, but the detailed actions are too complicated to be fully understood; some are beneficial, some harmful. X-ray treatment is still in the empirical stage.

Theoretical Applications.—As the scattering of X-rays is due to the electrons in material substances, the intensity of scattered radiation gives a measure of the number of electrons in that substance, and consequently the number of electrons in an atom. This is found to be precisely the atomic number of the atom: hydrogen, 1 electron; carbon, 6 electrons; nitrogen, 7 electrons; aluminium, 13 electrons; and so on.

The investigation of electrons ejected from substances by X-rays gives valuable information regarding the energy required to extract them, and thus of the structure of atoms.

X-ray spectroscopy reveals the atomic structure of crystals used to reflect the X-rays (see CRYSTALLOGRAPHY), and shows practically all solid substances to be composed of small crystals.

A study of the electrons ejected, and of the secondary X-rays emitted by substances exposed to primary X-rays, is the most promising line of investigation of those problems regarding radiation and matter, and the relation between them which are so baffling to the present generation; in particular, the problem of reconciling with the wave-theory those facts which seem to indicate that radiation is made up of indivisible bundles of energy or quanta. (See QUANTUM THEORY.)

Rood, is used of the Cross of Christ, the Holy Rood, and of crosses and crucifixes generally, but especially the great crucifix which in mediæval churches stood on the rood-screen (see SCREEN). As a measure of surface, a rood is the fourth part of an acre, and contains 40 square poles or perches, or 1210 square yards.

Roof. In warm countries, such as India, flat roofs, covered with cement, are usual. Those of Palestine, Egypt, and Assyria also were flat, and were composed of wooden beams covered with thick layers of earth. In milder and rainier climates, roofs sloping from a central ridge are the ordinary form. Great Greek

Fig. 1.

buildings were covered with marble slabs, carefully grooved together; in common Greek and Italian buildings roofing tiles are used. In the rainy climate north of the Alps steeper roofs are needed to throw off rain and snow.

Fig. 2.

Roofs well constructed serve to bind the walls together and strengthen the building; if too heavy they crush the walls. The actual covering of the roof and its supports are therefore made as light as possible, and the strength concentrated in 'principals' or 'tusses'. Fig. 1 represents a king-post roof (A being the king-post), and fig. 2 a queen-

Fig. 3.

post roof (B, B being the queen-posts). The latter is used for wider spans, and leaves the centre clear for attics. Early Christian basilicas (and prob-

ably the Roman basilicas) had such roofs. In the early Gothic style the king-post was carved and the tie-beam moulded. The Decorated style introduced an arch or a series of cants (fig. 3). As the style progressed carved braces were placed under the tie-beam, to support it; these were carved, and rested on elegant corbels, the spandrels between the braces and the wall being filled with tracery. In the Perpendicular style the central part of the tie-beam is cut away, and the beautiful hammer-beam roofs of the period become usual (see fig 4). The roof of Westminster Hall is one of the finest examples of this kind of roof. These open timber-roofs are much used in England both in churches and halls, but abroad chiefly in the latter, as the church roofs were more frequently vaulted. In

Fig. 4.

modern times, when great spans have to be roofed over, combinations similar to those used in lattice Bridges (q.v.) are required. Iron has been introduced, and by means of it, spaces of almost any width can be roofed over. See also CEILING, MANSARD ROOF, FAN-TRACERY, &c.

Rook (*Corvus frugilegus*), a species of Crow, common in Britain and in many parts of Europe and Asia, especially in northern and central regions. In late autumn there is a migration from the Continent to the eastern shores of Britain, and a return in early spring. Some of the characters of the rook have been contrasted with those of other species of *Corvus* in the article CROW. The plumage is bluish black; the forehead, cheeks, and throat are bare; the bill, legs, and feet are black. White and piebald spots sometimes occur. The rook does not breed till it is about two years old. The nest, built of twigs with a lining of grass and roots, is almost always on a lofty tree. The noisy cawing of the builders in March is one of the familiar signs of departing winter. The eggs (three to five) are bluish green with olive-brown markings. As to food, the rook is almost omnivorous, but it depends in great part on insects and grubs. Unlike the crow, the rook is characteristically a social bird, feeding in great flocks, nesting in rookeries, and sometimes combining to beat off a common foe. Confident perhaps in their numerical strength, and reliant on their habit of posting sentinels, rooks are by no means shy, for they sometimes nest in the trees of a town garden, and, though much afraid of a gun, soon grow accustomed to scarecrows and noise. They are very wide-awake birds, exhibiting no small degree of that acuteness which is often displayed by gregarious birds and

beasts. They show sagacity in choosing fit trees on which to nest, in posting sentinels who warn the others when danger threatens, and in distinguishing real from fictitious sources of alarm. Though quarrelling and mutual robbery are common during the nest-building, there is no doubt that rooks have a sort of social feeling, which manifests itself sometimes in the punishment which they inflict on an offending member. The same rooks seem to take possession of their old nests year after year, repairing the damage done by the winter storms. The male rook feeds the female assiduously during incubation, and sometimes takes her place on the nest. Both parents bring food to their young ones, and the nestlings are provided with little stones essential to the grinding of the food in the gizzard. The rook can be tamed, and may exhibit something of the imitative power possessed by several related birds. While rooks are useful in so far as they destroy

Rook (*Corvus frugugines*).

many injurious insects and grubs, they sometimes damage trees by breaking off the twigs, they root up grass and young corn, and do other damage to the crops. In moderate numbers they are useful, but in multitudes they are compelled to leave their natural food and become injurious.

Rooke, SIR GEORGE, British admiral, was born in 1650, near Canterbury, at the country-seat of his father, Sir William Rooke. Entering the navy, he found himself at thirty a post-captain, and in 1689 was promoted to the rank of rear-admiral of the red. He took part in the action off Beachy Head between the Earl of Torrington and a French fleet under Tourville; and in 1692 he distinguished himself greatly in the memorable battle off Cape La Hogue, fought between the French fleet and the combined English and Dutch force under Admiral Russell. For this he received the rank of vice-admiral of the red, knighthood, and a pension of £1000 a year. In 1702 he commanded the expedition against Cadiz, and destroyed the Plate-fleet in the port of Vigo. In conjunction with Sir Cloudesley Shovel he accomplished the capture of Gibraltar, 21st July 1704. On the 9th August of the same year he engaged off Malaga a much heavier French fleet under the Comte de Toulon, and fought one of the bloodiest of naval battles, the honours of which remained with the English. Finding the government hostile to him on political grounds, he retired from public life and led the life of a Kentish gentleman till his death, 24th January 1709. See his *Journal*, edited by Oscar Browning for the Navy Records Society (1897).

Roon, ALBRECHT THEODOR EMIL, COUNT VON (1803-79), born near Kolberg in Pomerania, entered the Prussian army in 1821, joined the general staff in 1833, and in 1859 was made war minister, and in

1861 marine minister as well. The effects of his labours in reorganising the army were brilliantly realised in the wars of 1866 and 1870-71, and he was made count (1871) and field-marshal (1873). He wrote two books on geography. See *Life* by Von Gossler (1879) and another *Life* (1888), and various collections of his reminiscences, letters, and speeches, edited by his son (1892-96).

Roosevelt, THEODORE, President of the United States, was born at New York on 27th October 1858, his father being of an old Knickerbocker family, his mother Georgian-Scots, while there was in his veins also Irish and Huguenot blood. At Harvard he was a distinguished athlete, and as a rancher in the wild west he became a mighty hunter of big game. In 1882-84 in the New York legislature he became known as a strenuous reformer of Civil Service abuses, was leader of the House in 1884, and as President of the New York Police Board (1895-97) carried through some much-needed improvements. As Assistant-secretary of the Navy in 1897 he did much to secure the efficiency displayed in the Cuban war; and at the outbreak of the war he raised a famous regiment of cavalry volunteers, the Roosevelt Rough Riders, and commanded them with brilliant success. In 1898 he was made governor of New York, in 1900 vice-president of the United States; and on the death by assassination of McKinley (September 1901) succeeded him as president. A Republican, a reformer of all administrative abuses, a declared foe to Tammany and the spoils system, an upholder of the Monroe Doctrine, and an expansionist, he substantially continued McKinley's policy, but showed more personal initiative, and was forward to recognise the independence of Panama (1903). He sought to secure full commercial rights for Cuba, insisted on the necessity for strict supervision of syndicates and rings, and incurred some loss of popularity by his resolute endeavours to give coloured persons the full rights of citizens and even social privileges. He took an active part in arranging peace negotiations between Russia and Japan after the war of 1904-5. On the expiry of his second term of office (1909) he went to hunt big game in Africa. His subsequent attitude towards President Taft and his 'Insurgent' movement were followed by disaster to the Republican party at the polls in 1910. In 1912 as head of the 'Bull Mooses,' a 'third party' of progressive Republicans, he stood, against Mr Taft, for progressive social, economic, financial, and constitutional legislation, as candidate for a third term of the presidency, and during his candidature was shot by an intending assassin and seriously wounded. In 1914 he explored the Brazilian Rio Duvida or Teodoro. He wrote books on hunting, ranching, zoology, history, an *Autobiography* (1913); and, with others, an elaborate book on the Deer family. He died 6th January 1919. See *Lives* by Thayer (1919) and Bishop (1920).

Root is the name applied commonly to the subterranean organs of flowering plants which absorb nutrient chemical solutions from the soil, and by growing and spreading in the latter serve also to maintain the plant in the best position for the development of its aerial portion, or shoot. But organs of the same kind, from the morphological point of view, may have different forms and different functions; thus shoots may function as roots, and roots may grow up into the air as shoots. See **PHYSIOLOGY (VEGETABLE)**.

As the leaf surface of a seed plant is developed, the root system grows; in a large sunflower it occupies about one cubic yard, in a large tree hundreds of cubic yards. This system, resulting from the branching of the primary, secondary, and other roots, the ultimate divisions consisting of

root-hairs, is so complete that scarcely the space of a quarter cubic inch is unoccupied. Abundance of water, to balance the transpiration, and of salts, for other purposes of plant life, is thus secured. The root system of aquatic plants is small, water being easily obtained and transpiration slight.

All roots at first are thin hair-like organs; the greater thickness that those of the dicotyledons attain is due to a secondary growth. The thickened roots serve only as organs of attachment, and of course as conducting channels, but not at all as organs of absorption. These absorbing parts, root-hairs, are protuberances of the outer layer of cells of the roots. They arise shortly behind the growing tip, and they die off in a few days, so that only an inch or two of root bears root-hairs. In this way the root-hairs are continually brought into contact with portions of untouched soil.

A longitudinal section near the apex of a root of a dicotyledon shows the following arrangement of parts. Near the developing apex a mass of actively dividing cells, known as the growing-point, gives origin to an exterior tissue of simple cells; this usually has the form of a thimble, well seen in common duck-weed, and is called the root-cap. In its rear the growing-point produces other cells but of a different nature. These cells soon enlarge and undergo modifications according to the elements of the root anatomy they are destined to produce. At about $\frac{1}{2}$ inch from the growing-point such cells have differentiated into three distinct layers recognised from without inwards as dermatogen, periblem, and plerome. These undergo further differentiation, so that a mature root consists of the following parts: (1) an outer layer, the epidermis, developed from the dermatogen; (2) several layers of simple cells, the cortex, developed from the periblem; (3) the fibro-vascular cylinder, and often a central pith, both developed from the plerome. The root-cap serves as a protection to the delicate growing-point of the root as it forces its way through the soil. It is continuously worn away by the particles of the soil, and as continuously reformed behind by the growing-point. The epidermis encircles the whole, and many of its cells develop into long hairs, the absorbing root-hairs already mentioned. The cortex, when young, may also absorb fluid from the soil, which together with that taken in by the root-hairs is passed inwards to the young wood-vessels, by which it is carried upwards to the shoot as the ascending sap. The cells of the cortex also conduct upwards for some distance a smaller proportion of the absorbed water of the soil. The bundle sheath, when it occurs, separates the cortex sharply from the rest of the root. The wood-vessels not only conduct the ascending sap, but afford, together with the wood-fibres and bast fibres, strength, toughness, and rigidity. The young fibro-vascular core, or cylinder when there is a central pith, is composed of from 2 to 8 or more groups of woody tissue and bast tissue, with arcs of cambium between them. These are arranged alternately in a star-like manner when there is no pith, or alternately in a circle about the central pith, when seen in a transverse section of the root.

Secondary thickening may occur in roots as in stems, and is due to the continued development of the arcs of primary cambium, combined with new cambial cells formed by the pericycle around the outside of the groups of woody tissue, until a complete girdle of cambium is produced. The new cambium ring seen in transverse section waves in and out so that it passes inside the bast bundles and outside the wood bundles. This cambium produces a new and entire ring of wood and bast similar to that formed by secondary thickening of stems (see STEM). Thickened roots always lose

their original cortex and epidermis, and gain a fresh covering in the following way. The young bast and woody tissues are surrounded by a ring of cells called the pericycle. This, besides taking part in the completion of the cambial girdle as just mentioned, forms by division of its outer cells an entirely new layer of cambial tissue termed the cork-cambium or phellogen outside of the bast or wood-cambium. This phellogen then produces on its inside a layer of tissue known as the phelloderm, and on its outside a similar, often thicker, layer termed the periderm or cork. The original tissues lying outside of the pericycle are thus split off and discarded as the root thickens. A third function of the pericycle is that of giving origin to all branches, i.e. rootlets which may arise. This delicate cylinder of pericyclic cells is therefore of the utmost importance to young roots.

Forms of Roots of Seed Plants.—The primary root is merely the enlarged radicle of the seedling; it is the direct prolongation of the stem. All secondary roots of dicotyledons arise from this first root; the secondary roots may give rise to others, and so on until a much-branched root is formed. If the primary root is very thin the whole system is called a fasciculated root; if the secondary fibres are also very fine it is called a fibrous root; if the fibres are very much thickened it is said to be a tuberous root (e.g. the dahlia). When the primary root is much thicker than the secondary roots it is called a tap-root, and may be further classified according to its shape, as spindle-shaped (e.g. the carrot) or turnip-shaped. Much-thickened roots are usually store-houses of food material—e.g. the fasciculated root of the Turk's cap lily, or the tap-root of the turnip. Roots are also described as fleshy (e.g. the beet-root), or as woody (e.g. the roots of trees). Fleshy roots usually die in the autumn of their first or second year; woody roots may live for many years, even when the shoots die down every autumn. Roots usually burrow in the soil, but they may be aerial, as for instance the roots of climbing plants such as ivy; these arise from the stem and fix the plants to their supports. In the tropics many plants have aerial roots, like the mangrove which forms forests in brackish swamps. The Indian fig has aerial roots from which, after they have become fixed in the ground, new plants may spring. Orchids are examples of the epiphytes, which have roots which merely fix the plants to trees but do not derive any nourishment from them. Aquatic plants often have roots which do not penetrate into the mud but float freely in the water. Many plants will form new roots after all the old ones have been cut off if they are placed in water or in a damp soil. This is taken advantage of by gardeners in their method of propagating such plants as fuchsias, oleanders, &c. from cuttings.

Esculent roots are numerous, and many roots also contain secretions either peculiar to themselves, or more abundant than in the other parts of the plant, and become therefore useful in medicine or in the arts, while some are very poisonous. The roots used for food are generally those which are thick and fleshy. The plants to which they belong are of very different genera and orders—some of the natural order Cruciferae, as the horse radish, turnip, radish, and kohl-rabi—some of the order Chenopodiaceae, as beet and mangold wurtzel—some of the order Umbelliferae, as the carrot, parsnip, &c. and some of the order Compositae.

Comparative.—Most of the Thallophytes (Algae, Fungi, and Lichens) have only a rudimentary differentiation into stem, leaf, and root, or none at all; but the most highly developed members of each division have an outward distinction of parts to which such terms may be given; still the roots

even of these are distinguishable from the roots of vascular plants not only by anatomical structure but by the absence of a root-cap, and by their branching, which is never endogenous.

The Vascular Cryptogams—ferns, horsetails, lycopods, &c.—are highly differentiated in form and in their tissues. The roots arise in acropetal succession on the stem, or in many ferns on the petioles; their branching is monopodial or dichotomous; they are all alike—the first root never becomes like a tap-root, the lateral roots arise from the innermost layer of the cortex, and the roots grow by successive divisions of an apical cell. The *Selaginella*, a group of the Lycopodiaceæ, are remarkable in that the growing-point is formed by a primary meristem similar to that of flowering-plants and not by an apical cell as in ferns and horsetails.

The roots of the Seed Plants have already received a general description, and a few other points may now receive consideration. The primary root is a continuation of the primary stem; it is directed towards the micropyle of the ovule and seed (see OVULE), and is of endogenous origin, its first rudiment being covered by the nearest cell of the suspensor. All the parts of the seed plants, shoots and leaves as well as roots, are distinguished from the parts of all other plants, except the *Selaginella* and for a short time the embryos of some Coniferae, by having a small-celled primary meristem at the growing apices instead of the typical apical cell of many Algae, and of the Bryophyta, Ferns, and Horsetails. The root-cap is formed, not as in the cryptogams, by transverse divisions of an apical cell, but by rapid division in the direction of the apex of the cells of the apical meristem. Also the first rudiments of lateral roots, shoots, and leaves do not arise from single cells, as in the cryptogams, but from protuberances of a few small cells. The formation of a complete cambium ring in the primary and stronger lateral roots, and the subsequent secondary increase in thickness, is a characteristic of gymnosperms and dicotyledons, and does not occur in the cryptogams. This habit often results in the formation of persistent root systems, which in the monocotyledons are often replaced functionally by rhizomes, tubers, and bulbs.

Many epiphytes of tropical forests, like Philodendron and other Aroidæ as well as many Orchids, produce large and long aerial roots that hang down into the moist air, from which they absorb water by means of a modification of the root-cap. On the other hand certain swamp plants, like *Jussiaea* (Onagraceæ) and *Taxodium* (Coniferae), which, owing to the water-logged soil of their habitat find respiration of their lower parts difficult, overcome this disadvantage by sending up into the air, vertically from the swamp, special roots called pneumatophores modified for the absorption of air.

The stems of the Cycadæ are exteriorly not unlike those of the Tree-ferns, but unlike them they have tap-roots and secondary roots which may appear above ground. In the Coniferae the endosperm bursts the seed-coat at the root end, and the root, which develops a strong tap-root with lateral members, is thrust out.

The primary root of monocotyledons soon ceases to grow, lateral roots spring from the axis, each new root springs from a point higher up the stem, and the new being stronger than the older ones, there is no secondary thickening and no persistent root system. Some saprophytic monocotyledons as well as many aquatic plants form no roots at all. In dicotyledons an axis below the cotyledons is called the radicle, but the upper and often the larger portion consists of a part of the stem called the hypocotyl; the lower part is the true embryo

root. The root is the first part to issue from the burst seed-coat; it grows and gives rise to lateral roots. If the primary stem grows vigorously the primary root also grows rapidly and forms a tap-root. If the growth ceases adventitious roots are often formed between the former lateral ones, which may themselves give rise to lateral roots. For further information, see the larger text-books of general or morphological botany.

Root. In Algebra, denotes any value of the unknown quantity in an equation which will render both sides of it identical. The determination of the roots of equations, either formally or actually, constitutes the greater portion of the science of Algebra (see EQUATIONS). The *square* root is that number which, multiplied by itself, produces the given number; the *cube* root, the number which, multiplied into itself and then into the product, produces the given cube; so with fourth root, fifth root, &c. (see INVOLUTION).

Root and Branch Men. a party in the Commons and out of it who supported a petition signed by 15,000 London citizens, praying that episcopacy might be destroyed 'root and branch.' Nathaniel Fiennes, Sir Henry Vane, and Hampden were of the party. A bill to give effect to the petition was read a first and a second time in 1641, but was ultimately dropped.

Rootstock. See RHIZOME.

Ropes. The staple fibre for ropes has long been Hemp (q.v.), but since the middle of the 19th century several other fibres have come largely into use. Hemp is better suited for cordage (the general term for ropes, cords, and twine of all kinds) than for weaving purposes, because it gives way when much folded into sharp folds more readily than other important textile fibres—flax, for example. Manila hemp (*Musa textilis*; see ABACA), belonging to a quite different order of plants from the common hemp, is largely employed. Coir fibre, from the husk of the coconut, is another important rope-making material which, though long used in India, has in Europe only taken its place as a valuable cordage fibre more recently. It is fairly strong, and, size for size, it has the advantage of being considerably lighter than either hemp or manila. Unlike these, coir rope is never tarred for preservation. Sisal hemp, from the *Agave sisalana* of Yucatán though not nearly so strong as common hemp, is also much used, especially for ropes of small size. For certain purposes, such as driving parts of textile machinery, cotton ropes are largely employed. The British Admiralty accepts ropes supplied to it consisting of Italian hemp or Russian hemp, or a mixture of the two up to a *circumference* of six inches, while Bombay hemp may be used in the mixture or alone between six and sixteen inches. Manila fibre is accepted for ropes of three-quarters to three inches. There are two other rope fibres which are of increasing importance in Britain—viz. the Sunn hemp (*Crotalaria juncea*) of India and the *Phormium tenax* of New Zealand. A large number of plants valuable for cordage grow in India, for a list of which, as well as for an account of the native process of rope-spinning, see Balfour's *Cyclopædia of India*, or the Indian exhibit at the Imperial Institute.

As regards the strength of ropes, it will be readily understood that in this respect specimens of the same kind of vegetable fibre will vary considerably. Healthy plants will yield a better fibre than those of more feeble growth, and some supplies of the same kind of material will have been more carefully prepared for spinning than others. The amount of care and skill bestowed upon the spinning process itself will also vary in the case of

different manufacturers. Tarred ropes, again, though more durable, are not so strong as those left untarred; and as tar is liable to be impure it will happen that it weakens or injures the fibre more at one time than at another. Ropes are made in coils to a finished length of 113 fathoms, and are tested by ascertaining the breaking strength of a free length of one fathom. The size of yarns is given thus, 40 thread, 30 thread, &c., and the number of yarns to be worked into a given size of rope is specified, together with the weight of a coil of finished rope. The table gives particulars of a few representative cases:

Size in Inches Circumference	Breaking Strength of Yarn in lb	No. of Yarns in Rope	Threads	Approximate Breaking Strength of Rope in lb	Approximate Weight of a Coil in lb
Hemp	8½	15	40	1340	27
“ 2	8½	54	40	4000	96
“ 3½	120	120	30	9400	211
Manilla					
Fibre 1	120	15	40	1120	25
“ 2	120	54	40	3700	83

The safe load for new ropes may be obtained by dividing the breaking strength by a 'factor of safety' of from 5 to 7. Tarred rope is 10 to 15 per cent. weaker.

The term rope is applicable only when the circumference of the cordage exceeds 1 in.; smaller cordage is called cord-line or twine. Ropes 1 in. to 2½ in. circumference are 'hawser' laid, 3 to 10 in. circumference are 'hawser' or 'cable' laid, and above 10 in. circumference are 'cable' laid. The general method of procedure in making ropes by machine is as follows: 'The yarns being wound round on the bobbins in suitable numbers, according to the size of the rope to be made, they are from each bobbin threaded through a head-runner (register-plate) of six holes, and gathered at a die, at which they are closed into strands, there being a separate die for each of the three strands. The strands being formed, they are then threaded through a main head-runner of the holes, and immediately closed at the main closing die into finished rope. The rope is drawn through the die by means of strong hauling-off drums, and ultimately wound on a storage reel.' In making cables, sufficient fibre is taken and twisted to the right to form yarn, then yarns are taken and twisted to the left to form strands, then these strands are twisted to the right to form hawsers, and hawsers are twisted to left in the formation of cables. This reversal tends to keep the rope together and the fibres parallel to the direction of stress.

In this country ropes were usually specified by their circumference, but in America the diameter is more usually given; both methods are now in common use, and it is necessary to state whether diameter or circumference is meant, in order to avoid confusion.

Ropewalk Spinning.—Notwithstanding the successful application of machinery to the manufacture of ropes, the old process of ropewalk spinning is still practised on a considerable scale. The successive stages in the process are (1) heckling the fibre; (2) spinning the yarn; (3) larring in 'hanks' consisting of about 300 yarns, laid close and parallel in lengths of say 100 yards; (4) winding the yarn on bobbins and mounting these on bobbin-frames; (5) forming the strands; and (6) laying the strands into a rope. The heckling of hemp is done in the same way as the heckling of flax (see LINEN), the object being to remove the tow or short fibres and to place the long fibres called 'line' parallel to each other. Spinning in this process is done by hand, but either an iron whirl hook, forming the spindle of a small pulley, or, what is of more recent intro-

duction, a similar hook with a small cone upon it, is kept in motion for the spinner. Several of the former are mounted on a circular frame, and driven by hand or power; but a set of the latter, which automatically fall out of gear by weights when the spinning is interrupted, are arranged in a straight line, because they are driven by the friction of larger cones fixed on a shaft, and there may be twelve of either kind of hooks forming a set. The spinner wraps a quantity of the heckled hemp round his waist, and attaches some of the fibres to one of the hooks, which by its revolving motion twists them as he continues to pull out and regulate the supply of fibres with one hand, and press them into proper form with the fingers of the other. He carries in his right hand a piece of woollen cloth, with which he grasps the fibres, and walks backwards, while he spins, to the farther end of the long covered walk.

The hauls of yarn are tarred by passing them through Archangel tar, heated to 240° F., a nipping apparatus being used to regulate the quantity taken up by the fibre. The next step is to wind the yarn on bobbins, which are then placed on a vertical frame. In order to form a strand of say ten yarns, one from each of ten bobbins is drawn through as many holes in a metal disc or register-plate, and immediately afterwards brought together and formed into a compact bundle of yarns by passing them through a stranding tube. On emerging from this the strand is fastened to the rotating hook of a forming machine on a travelling carriage, which, by means of proper gearing, is drawn along the walk, giving at the same time the proper twist to the strand. In this way three or more strands are formed at the same time by the machine. These are then laid into a three-stranded rope or 'hawser' by attaching them at one end to the centre hook of the machine, while the other extremities of the strands are attached to three hooks. At that end where they are hung together on one hook the three strands are kept equidistant by placing them into the three longitudinal grooves of a conical piece of wood, called a 'top.' The twisting of the strands is effected by the rotation of the hook, from which the top recedes as the rope is formed. As the twist of the laying is in the opposite direction to the twist of the strands, the single hook requires to be turned in a contrary direction to the other three. A hawser has either three or four strands, the latter being said to be 'shroud hawser laid.' It requires a core-piece, and is much used for trawling. A Cable (q.v.) is a thick rope with usually nine, sometimes twelve strands.

Rope-making by Machinery.—By this is understood the making of ropes by machines which do their work without the necessity of having a ropewalk. The heckling, the drawing, and the spinning frames for preparing rope yarns are the same in principle as the corresponding machines used for spinning linen yarn for weaving purposes. There is, however, some difference in detail, owing to the greater average weight of rope yarn, so that, for example, there are comparatively few bobbins on the spinning-frame proper. Separate machines are perhaps less generally used for making strands and for laying these into ropes than compound machines which perform both operations, except for very thick ropes. All these are now made of different designs, and with a good deal of variety in their details.—Wire-ropes and textile fibre ropes are now largely employed for driving machinery instead of belting. See also *Rope, Twine, and Thread Making*, by H. R. Carter.

Roque (Lat. *Rocheus*), St., the patron saint of those sick of the plague, and the enemy of cattle-plague. He was born in Montpellier about 1295,

devoted himself to the care of persons suffering from the plague, especially in Italy, and died in 1327.

Roquefort, a village in the French department of Aveyron, situated on the western edge of the Causses plateau, 44 miles N. by W. of Béziers and 10 S.W. of Millau, and celebrated since Roman times for its ewe-milk cheeses.

Roraima, an isolated, table-topped sandstone mountain, near the west border of British Guiana. First sloping gradually upwards 5000 feet above sea-level (2500 above the plain on which it stands), it next shoots up 2000 feet more in a perpendicular stupendous cliff, over which drop numerous waterfalls. It was first scaled by Sir E. P. in Thurn on 18th December 1884.

Rorke's Drift, a station on the Buffalo River, Zululand, South Africa, memorable for the heroic defence of Lieutenants Chard and Bromhead, with eighty men of the 24th Regiment, who had been left to guard the commissariat stores and the hospital of Lord Chelmsford's force, against 4000 Zulu warriors during the night of the 22-23d January 1879, the night after Isandula. The only defences of the British were an extemporised rampart of rice bags and biscuit boxes, yet they kept the enemy at bay, and six times in succession drove out parties who had got within the barricade.

Rorqual (*Balenoptera*), a kind of baleen whale, to which the names of *Fin-back*, *Finner*, and *Bazow-back* are also applied. The genus includes the largest and some of the commonest whales, and is represented in all seas. The head is flat and pointed, the body is slender, the skin of the throat is deeply folded in longitudinal plaits, the whalebone is short and coarse, and there is not much blubber. The 'blue whale' (*B. sibbaldii*), the largest living animal, may attain a length of 80 or 85 feet. It seems to pass the winter in the open sea, and approaches the coast of Norway at the end of April or beginning of May, and is sometimes stranded on British coasts—for instance, in the Firth of Forth. The Common Rorqual (*B. musculus*) attains a length of 60 to 75 feet, and it often comes ashore on British coasts. Randolph's Whale, or Northern Rorqual (*B. borealis*), does not exceed

Northern Rorqual (*Balenoptera borealis*).

50 feet in length; and yet smaller is the Lesser Rorqual (*B. rostrata*), which measures about 30 feet. The former is not uncommon in the more northern seas, while the range of the latter extends from the Mediterranean to Davis Straits. The rorquals seem to feed on small crustaceans, and sometimes on small fishes. Though not nearly so valuable as species of *Balaena*, they are often captured by the whalers. See **WHALE**.

Rosa, CARL, whose real surname was ROSE, impresario, was born at Hamburg on 22d March

1843, and studied music at Leipzig and Paris. After conducting a concert and operatic tour in the United States in 1871-72, he came to England, his intention being to produce standard operas with an English text. But it was 1875 before he was able to carry out his intention. London gave him little encouragement; the prejudice against English opera was too strong. The provinces, however, welcomed the new undertaking and made it successful. Carl Rosa may be called the father of English opera in two senses: he not only produced the great operas of German, French, and Italian composers with English texts, but he encouraged native composers to write opera, by giving them commissions for works. He died on 30th April 1889.

Rosa, MONTE. See MONTE ROSA.

Rosa, SALVATOR, was born at Arenella, in the neighbourhood of Naples, on 20th June (or 21st July) 1615. In his youth he got a little instruction from Falcone, a painter of battle-scenes, but spent most of his time wandering amongst the wild and romantic scenery of Southern Italy, copying from nature. Some of his landscapes attracted the notice of the painter Lanfranco, who encouraged the young artist to go to Rome (1635). The next three years he passed alternately in Naples and in Rome, and leaped into fame with a picture, 'Titans tortured by the Vulture.' He then settled down in Rome, but seems to have been in Naples at the time of Masaniello's revolt (1647), though it is uncertain whether he bore arms in support of the Fish-er Lad. (It seems not to be true that he lived with landits in the mountains in his youth.) At Rome his social talents—he was a skilful musician, improvisatore, actor, and poet—his merry humour, his wit, and his princely generosity made him a great favourite. But he made powerful enemies by his satires, clever productions in verse, and withdrew to Florence, where he remained nearly nine years. After that he returned to Rome, and died there on March 15, 1673. Salvator has a great reputation as a painter; this he owes mainly to his landscapes, which, though in many respects faulty, are original in subject and treatment, being generally representations of wild and savage scenes, executed with considerable freedom and energy. His historical pictures are not so good, though they are those he himself thought most of. He executed numerous etchings, highly characteristic of his peculiar style. His *Satires* were published in 1719. See *Life* by Baldinucci (new ed. 1830) and by Canth (1844). Lady Morgan's book (1824) is a blending of fact and romance.

Rosacea. See ACNE.

Rosacea, a family of dicotyledons, containing many species of great usefulness, and many that are in the highest esteem for their beauty and fruit. It contains trees, shrubs, and herbaceous plants, natives chiefly of cold and temperate regions, and far more abundant in the northern than in the southern hemisphere. Within the tropics they are chiefly but not exclusively found in elevated situations. The leaves are alternate, have stipules, and are either simple or compound. The flowers are generally hermaphrodite, but sometimes unisexual; the inflorescence various. The calyx is 4 to 5 lobed, generally 5-lobed; the petals as many as the divisions of the calyx, or occasionally wanting, perigynous. The stamens are few or many, arising from the throat of the calyx; the ovary is sometimes solitary, sometimes there are several ovaries, each one-celled, with a lateral style, or a number of ovaries are united into a many-celled pistil; the ovules generally two or more. The fruit is sometimes a drupe; sometimes a pome; sometimes follicular; sometimes a nut;

sometimes a collection of nuts enclosed in the fleshy tube of the calyx; sometimes a collection of small drupes forming a head, as in the raspberry and sometimes, as in the strawberry, it is an enlarged fleshy receptacle with the seeds imbedded on its surface. This family contains about 2000 known species; but in some of the genera, as *Rosa* and *Rubus*, the determination of the species is attended with great difficulty, and varieties—some times reckoned species—are numerous. See APPLE, PLUM, ROSE, RUBUS, STRAWBERRY, POTENTILLA, AGRIMONY, GEUM, SPIRÆA, CUSSO, &c.

Rosamond. See ALBOIN, CLIFFORD.

Rosario, the second city of the Argentine Republic, and the largest in Santa Fé, is on the west bank of the Paraná, 190 miles by rail N.W. of Buenos Aires, 210 miles by river. It has an excellent harbour, accessible to steamers of 10,000 tons, and carries on a large commerce direct with Europe. It is especially a great wheat-port, and is also the junction of three separate systems of railway. The houses for the most part are of a single story; and for the rest, the city is laid out, on a smaller scale, on the lines of Buenos Aires. It has an extensive tramway system, an exchange, a theatre, a great bull-ring, a racecourse, hospitals, factories, &c., as well as two institutes—one for mathematics and chemistry, and the other for economics. Pop. (1887) 55,000; (1901) 112,461; (1922) 265,000.

Rosary, a string of larger and smaller beads used by Catholics as an aid to memory in keeping account of the number of Paternosters and Ave Marias recited. There are various patterns in use; a very ordinary one is a rosary of fifty-five beads, fifty small ones for the Ave Marias, separated into groups of ten by five large ones to mark Paternosters. The custom of reciting the Lord's Prayer many times in succession dates from a very early period of the Christian church; the custom of keeping a note of the prayers recited by means of strings of beads was so common in the East amongst Hindus and Mohammedans that the use of the rosary for this purpose has been said to have been introduced into Christian Europe by the Crusaders. The name (Lat. *rosarium*, 'a garden of roses' or 'chaplet of roses') first occurs in the 13th century, and seems to be derived from *Rosa mystica*, a term given to the Virgin herself, or from a set of prayers being thought of as the Virgin's rose-garden; less probable is the suggestion that the name comes from the beads being originally made of rosewood. The beads are now of various material—berries, wood, stone, ivory, metal, &c., and are often of costly workmanship, and of considerable intrinsic value. They are blessed for the use of the people by the pope, by bishops and superiors of religious orders, and by others having special power for the purpose. The name is also given to a series of prayers ('Rosary of the Blessed Virgin') consisting of fifteen decades, comprising fifteen Paternosters and Doxologies, and 150 Ave Marias, divided into three parts. The Lesser Rosary consists of one of the three parts, comprising five decades or mysteries.

ROSARY SUNDAY, the first Sunday in October, is a feast instituted by Gregory XIII. for the Confraternity of the Rosary, and made of universal observance after the victory of the Emperor Charles VI. over the Turks, in gratitude to the Blessed Virgin. An impetus has been given to the devotion of the rosary by Leo. XIII., who enjoined its daily use in public during October. In London roses are blessed and distributed as souvenirs, and the rosary recited continually during the day.

Rosas, JUAN MANUEL, Argentine dictator, was born in Buenos Aires, 30th March 1793, entered the army of Buenos Aires in 1820, was

appointed commander-in-chief in 1826, and was governor of the province from 1829 to 1832. Then, being disappointed of re-election, he headed a revolt, and in three years succeeded in obtaining office again, with extraordinary powers. From 1835 to 1852 he governed as dictator, not of Buenos Aires alone, but practically of the interior also. His rule was a rule of terror and nearly constant bloodshed; one of his chief opponents published, so early as 1843, a detailed list of 22,405 victims of the relentless savagery with which he pursued his policy of extirpation against the Unitarians (the advocates of centralisation, that is to say, as opposed to the Federalists, for whose principles Rosas professed to contend). Many refugees found an asylum in Uruguay, and therefore Rosas willingly supported the attempt of his partisan, General Oribe, to make himself master of the neighbouring republic; and, after the fall of Oribe's government, Rosas in 1839 invaded Uruguay with 7000 men, was defeated, and in 1843 sent Oribe back with an army of 14,000 men to attack Montevideo. The long siege which followed led to the joint intervention, in 1845, of England and France, the blockade of Buenos Aires (1845-47), and the temporary opening of the Paraná to free navigation. But the river provinces could not be induced to rise against Rosas, until in 1849 a treaty was signed by which he secured for Buenos Aires the entire navigation of the Plate, the Uruguay, and the Paraná. This roused the other provinces, and in 1851 Urquiza, the governor of Entre Ríos, supported by Brazil with both money and men, defeated Oribe in Uruguay, and won over his troops; then, with a force of 30,000, he marched against Rosas, and on 3d February 1852 routed him at Monte Caseros, near Buenos Aires. Rosas escaped to England; and, although the Argentine congress in 1861 condemned him to death as a 'professional murderer and robber,' specifying 2034 assassinations carried out by his orders, he lived comfortably near Southampton till his death, 14th March 1877.

Roscellinus. See SCHOLASTICISM.

Roscher, WILHELM, the most eminent expounder of the historical school of Political Economy (q.v.) in Germany, was born at Hanover on 21st October 1817. He studied at Göttingen and Berlin, and in 1843 was appointed professor of Political Economy at Göttingen, but in 1848 was called to fill the corresponding chair at Leipzig. His principal books are *System der Volkswirtschaft* (5 vols. 1854-94; 21st ed. 1894; English translation, 2 vols. Chicago, 1879), *Die Nationalökonomie des Ackerbaues* (10th ed. 1882), *Grundlagen der Nationalökonomie* (17th ed. 1884), *Geschichte der Nationalökonomie in Deutschland* (1874), *Zur Geschichte der englischen Volkswirtschaftslehre 1851-52*, *Kolonien, Kolonialpolitik und Auswanderung* (3d ed. 1885). He died 3d June 1894.

Roscius, QUINTUS, was born at Solonium, a village near Lanuvium, and rose to be the greatest comic actor in Rome. So much was he admired that many of the Roman aristocracy befriended him, and the dictator Sulla, as a token of favour, presented him with a gold ring, the symbol of the equestrian order. Among his most admiring and affectionate patrons Roscius also numbered Cicero, who, at the commencement of his career, received lessons in the art of elocution from the great comedian, and even in later life used to make trials of skill with his instructor as to which of them rendered a thought most clearly and effectively—the orator by his diction, or the comedian by his gesticulation. So sensible was Roscius of the distinction he enjoyed in sharing the intimacy, and even the friendly emulation of the great orator, that he came to look upon his art as one of no

small importance and dignity, and wrote a treatise on the comparative methods and merits of eloquence and acting. Cicero's friendship was of use to him in another way, for on his being sued at law by C. Fannius Chærea for the sum of 50,000 sesterces, Cicero defended him before the iudex Piso (probably 68 B.C.) in his extant oration, *Pro Q. Roscio Comædo*. He died 62 B.C., having attained such perfection in his peculiar art that to be a 'Roscius' became synonymous with pre-eminence in the profession, and leaving, like his famous contemporary, Æsopus the tragedian, an immense fortune, realised upon the stage.—For the 'Young Roscius,' see BETTY.

Roscoe, WILLIAM, historian, was born at Liverpool on 8th March 1753, his father being a market-gardener. In 1769 he was articled to an attorney at Liverpool, and began to practise there on his own account in 1774. During this period he assiduously cultivated his mental powers, turning his attention especially to the Italian language and literature. In 1773 he first appeared in print as the author of a poem, *Mount Pleasant*, now forgotten; and in 1787 he published *Wrongs of Africa*, a courageous protest against the slave-trade. But it was his *Life of Lorenzo de' Medici, called the Magnificent* (1796), which established his literary reputation; it went through several editions, and was translated into German, French, and Italian. In 1805 appeared his second important book, *Life and Pontificate of Leo X.* This, like the former, appeared in German, French, and Italian, and was received with much commendation, though its tone and spirit, especially with reference to the Reformation, were severely criticised. About the year 1800 he became partner in a Liverpool bank, a step which involved him eventually in great pecuniary embarrassment. From his pen came, besides the above-mentioned books, a collection of *Poems* (1857), of which by far the best known was the *Butterfly's Ball*; also a *Memoir of E. R. Jones* (1822). He issued an edition of Pope in 1825. Roscoe died at Liverpool, June 30, 1831. During the later years of his life he gave much attention to the study of botany, and wrote a monograph on Monardrian plants. See *Life* by his son Henry Roscoe (1833), and Espinasse's *Lancashire Worthies* (2d series, 1877).

SIR HENRY ENFIELD ROSCOE, chemist, born in London 7th January 1833, was a grandson of the above, and the son of Henry Roscoe, barrister. He was educated at the Liverpool High School, and later at University College, London, and at the university of Heidelberg. He was professor of Chemistry in Owens College, Manchester, for thirty years from 1857, and rendered valuable services towards the organisation of that institution, and the furthering of scientific education in England. He was member of parliament for the south division of Manchester in 1885-95, and served on various Royal Commissions. He was elected a Fellow of the Royal Society in 1863. He was president of the Chemical Society in 1880, of the Society of Chemical Industry in 1881, and of the British Association at the Manchester meeting in 1887. He was vice-chancellor of London University 1896-1902, and in 1909 was made a privy councillor. Of his original contributions to chemical science the most important are researches on the measurement of the chemical activity of light, and on vanadium and its compounds. His published works include *Spectrum Analysis* (1868); his well-known *Lessons in Elementary Chemistry* (1870); his *Treatise on Chemistry* (with Schorlemmer, 1878-89; new ed. 1905-7); and books on Dalton and the atomic theory. See his autobiographical *Life and Experiences* (1906). He died 18th December 1915.

Roscoff, a seaport on the north coast of the French department of Finistère (long the headquarters of smuggling into England), 33 miles N.E. of Brest. The men are all sailors; the women grow vegetables, as the soil is considered to be especially fertile. The place is resorted to for sea-bathing, and there is a marine zoological station. The garden of the Capuchin monastery contains a fig-tree whose branches, trained over scaffolding, could give shelter to 200 people. Pop. 4000. Here Mary, Queen of Scots, landed in 1548, and the Young Pretender after his escape from Scotland.

Roscommon, an inland county of Connaught, Ireland, is bounded on the E. by the Shannon, and on the W., in part, by the Suck; it is 62 miles long from north to south, by 35 miles from east to west. Area, 608,290 acres, of which about one-fifth is under crops; more than one-half is permanent grass. It belongs to the central plain of Ireland, but rises in the north into the Curlew (800 feet) and Branlieve (1377 feet) Mountains. Several lakes occur, as Allen, Boderg, and Rec, expansions of the Shannon, and Key, Gara, and Glinn in the north-west. The soil in the central districts is in general light, but fertile, and affords some of the finest sheep pasture in Ireland in the 'Plain of Boyle.' The chief industry is the feeding of sheep and cattle, especially the former. Coal and iron exist, but are not worked; there are no manufactures. The chief towns are Roscommon, Boyle, Castlebar, Elphin, and Strokestown. Pop. (1841) 254,551; (1861) 157,272; (1881) 132,490; (1911) 93,956, most of whom are Roman Catholics. Roscommon sends four deputies to the Dáil Éireann. It possesses a number of Celtic antiquities, raths, &c., several remains of strong castles, and some fine ecclesiastical ruins.

ROSCOMMON, the county town, 96 miles W. by N. of Dublin, dates from the 13th century, when it arose around a Dominican abbey, founded by the O'Connor in 1257, and a castle built ten years later by Sir Robert de Ufford; the remains of both still exist. Pop. 1800.

Roscrea, a market-town of Tipperary, Ireland, 77 miles S.W. of Dublin, is a very ancient town; here St Cronan built a church, and had a celebrated school in the 7th century. Considerable remains of a castle, a lofty round-tower (80 feet high), and ruins of two abbeys exist. Pop. 2200.

Rose. The rose, the most lovely and fragrant of flowers, the favourite of poets and the national emblem of England, is a shrub or sometimes a tree, very widely distributed, giving name to the large and comprehensive family Rosaceæ, to which some of our choicest fruits belong. Restricting ourselves to the genus *Rosa*, which alone we acknowledge as the rose, we find the characteristics thus: shrubby growth, stems generally prickly, leaves alternate, stipulate, flowers terminal, often corymbose, spreading with five petals, in colour white, yellow, pink, or red, stamens numerous, styles exserted, seeds (achenes) numerous, enclosed in a fleshy berry, globular or ovate, which is known as the hip or hiep, and is in some sort edible. The calyx is generally five-lobed, and the lobes are more or less pinatised, and sometimes (as in the moss rose) furnished with a beautiful process of filament.

(1) Wild roses are natives of the northern hemisphere, found in all temperate climes, and even as far south as Abyssinia, the Indian Peninsula, and Mexico, extending also to the arctic zone, and of such variability that the discrimination of species is difficult. In Britain we find indigenous *Rosa spinosissima* (the Burnet-rose, from which descend the many varieties of Scotch rose); *Rosa canina* (the Dog-rose of our hedges,

with several sub-varieties); *R. Eglanteria* and *R. micrantha*, well known as the Sweet Briers; *R. arvensis*, a prostrate and unfragrant kind; *R. tomentosa* and *R. villosa*, having downy foliage and deep-red blossoms; and some others.

(2) The cultivated rose is a fuller and generally larger form, obtained by the nurture and skill of the gardener, and still receiving improvement by skilful crossing and loving observance. Garden roses have been marshalled into groups: *Simplicifoliae*, *Systyle*, *Banksianae*, *Bracteatae*, *Centifoliae*, and *Canine*. But the general grower may be well content to classify roses as 'summer' and 'perpetual'; though the principle of division is not botanical, neither is the division always justified by fact.

Summer roses bloom for the most part in June and July. Many of them are of the greatest beauty—for instance, the Moss rose, perhaps the loveliest of all flowers; and some are the best of all

for trellis or for pillar, and the hardest in bad weather. A Perpetual, or *Remontant* rose, as the French more correctly term it, instead of making growth alone after the gorgeous summer show, affords a succession, more or less continuous according to variety and weather, of bud and bloom until the frosts forbid. Yet even with these it is rare to find the aftermath of beauty as free or as fine as the summer crop had been; and many of the so-called perpetuals retire as meekly as the summer rose, especially in dull seasons. Perpetual roses include: the Chinese or Monthly, the Hybrid Perpetual, the Tea-scented, Bourbon, Noisette, Macartney, Ragosa, Microphylla, Lawrenciana, and Perpetual Scotch. The old Chinese, *Rosa indica*, commonly called the Monthly Rose, is still popular as an early and abundant bloomer; so are the Bourbons and Noisettes. But the Hybrid Perpetual and Tea-scented are chief favourites. Of these, many place the Tea first, for its exquisite refinement, grace, and delicacy, bewitching modesty, and pensive charm. But the hybrid perpetual claims bolder brilliance, more velvety damask, and profundity of glow. And indeed it seems difficult to achieve or conceive more perfect beauty than has already been attained by loving ingenuity and persevering skill in many of the roses we now possess; though many gardeners are hankering still for a blue rose, which would not accord with the form and tint of the foliage if they got it.

Roses are also divided, according to the form of flower, into globular, cupped, compact, and expanded, the last named often becoming reflexed in the later stage of bloom; and again, according to modes of culture, into standards, half-standards, pyramids, bushes, pendulous, pillar, and trellis form.

The question of stock must also be discussed, without acrimony if possible, though upon no other has there been so hot a war of roses. For any kind that is strong enough in constitution to support itself its own roots are the best feet and feeders, ousting all trouble of suckers, and often affording renewal by means of young shoots. But many of the fairest and sweetest, especially of the tea-scented class, require stouter sustenance, and must be budded or grafted on a more robust variety. The stocks chiefly used by our nurserymen are the Dog-rose, *Manetti*, and *De la Grifferae*; and the first is procured in three different ways—from its home in the hedges, or from cuttings, or from seed; and each way has its advocate. Others prefer the *Manetti*, a seedling Italian rose, as stock; and some, especially of the tea varieties, do best upon *La Grifferae*. But as a rule the *Manetti* is a treacherous foster-mother, affording brief vigour, and encroaching with deceptive suckers. Whatever stock may be chosen, the nobler rose is worked upon it, either by budding or grafting, and must engross the entire resources.

Again there are roses not a few, of delicate constitution or feeble habit, which should be grown in pots and sheltered through the winter. Many also of the stronger kinds are cultivated thus to bloom in the winter and spring, and some are of little value otherwise. But they must have plenty of air and light, and will not endure strong forcing.

New varieties of the rose are loudly hailed every year, and every season adds one or two lasting names to the lengthy catalogue. But old friends also pass out of date, and are no longer heard of; sometimes from a real advance upon them, sometimes from their own relapse. The crossing of the flowers is a process needing both judgment and dexterity. But the general grower will be content to cultivate the established kinds, which require no great trouble. Their abode must not be overhung, nor beset with stagnant water, the soil should be rich and deeply delved, and well-compressed round the neck of the plant. Plenty of water must be given in time of drought, and a mulching of good manure is welcome, and the growth of leaf and bud must be secured from countless enemies by daily and even nightly care. Three-quarters of the buds should be nipped off when true discretion orders it. As soon as the first flush of bloom is past, a little judicious pinning helps the prospect of a later crop; for the winter there should not be much shortening of the branches, unless they are threatened by the wind; but the general pinning remains for March.

See Ella Willmott, *The Genus Rosa* (1914); books by W. Paul (new ed. 1908), Dean Hole, Ellwanger (New York), Baker, Cranston, Rivers, Shirley Hibberd, Sawyer; and French books by Jamin and Forney, Singer, and Lacharme. See also *PERFUMERY, OTTO OF ROSES*; and for the Roman de la Rose, see CHAUCER, MEUNG, and FRANCE. Rose is a name for *Erysipelas* (q.v.).

Rose. SIR HUGH See STRATHNAIRN.

Rose. JOHN HOLLAND, born at Bedford in 1855, became professor of Naval History at Cambridge in 1919. He wrote *A Century of European History, The Rise of Democracy*, a critical Life of Napoleon I., and other works on Napoleon and on Pitt, *The Development of the European Nations, 1870-1914*, and *Hood and the Defence of Toulon*.

Rosebery, ARCHIBALD PHILIP PRIMROSE, EARL OF, was born in London, 7th May 1847, was educated at Eton and at Christ Church, Oxford, and succeeded his grandfather as fifth earl in 1868. He entered parliament in 1871, acquired in unusual measure the goodwill of the democracy, and was everywhere welcomed as an effective and entertaining speaker. In 1874 he became president of the Social Science Congress, in 1878 Lord Rector of Aberdeen University, and in 1880 of Edinburgh. From 1881 to 1883 he was Under-secretary for the Home Department, and in 1884 became First Commissioner of Works. In Mr Gladstone's next short administration (1886) he was Secretary for Foreign Affairs, an office he held till the fall of the government six months later; but even in that short period he established for himself a high reputation. In 1883-84 he visited Australia; and he has strongly supported Imperial Federation. In 1884 he moved for a select committee to inquire how best the efficiency of the House of Lords might be improved. He presented a magnificent swimming-bath to the People's Palace in the east end of London, in token of his interest in all movements for the social improvement of the people. In 1889 he was elected by the City Division to the London County Council, and was successful and assiduous as its first chairman till he resigned in 1890. He was re-elected and acted for a few months in 1892, till the political duties of an approaching general election led to his resignation. When Mr Gladstone resumed office in 1892 Lord Rosebery again became Secretary for Foreign Affairs, displaying, as on the former occasion, a tact and fineness that seemed the approval of all parties. On the resignation of Mr Gladstone in 1894, Lord Rosebery became the head of the Liberal ministry; but having failed to conciliate the hearty support of the various sections of his party, he resigned the premiership. A general election (July 1895) returned an overwhelming majority for Lord Salisbury; and in 1896, finding himself out of sympathy with Mr Gladstone on Armenia, he resigned his leadership of the Liberal party. Thenceforward he 'ploughed a solitary furrow'—often, as in the troubles with France about Fashoda and in foreign policy generally, supporting the Unionist government. He became the head of the Imperial League on the Liberal side during the Boer war; the Nationalists thought him worse than Inkewarm on Home Rule; and in the crisis preceding the Unionist *débâcle* of 1906, while keenly opposing both Mr Chamberlain's and Mr Balfour's schemes of tariff reform, he declared he would never fight under a Home Rule banner. In the crisis of 1909-10 he again took up a position apart from either party, and in 1910 brought forward a scheme for reform of the House of Lords. He was made Earl of Midlothian in 1911. During the Great War he delivered patriotic speeches, but ill-health has withdrawn him from public life. Lord Rosebery is keenly interested in Scottish history and literature, and as president has taken active part in the work of the Scottish History Society. A devotee of the Turf, he won the Derby in 1894 and 1895. An eloquent orator, he is also gifted with a superb literary style, which has found expression in several publications, including *Pitt* (1891), *Napoleon, the Last Phase* (1900), and *Chatham: Early Life and Connections* (1910). Two volumes of his speeches were published in 1921. See the *Life* by Miss Stoddart (1900) and E. T. Raymond, *The Man of Promise* (1923).

Rose-Chafer (*Cetonia aurata*), an injurious beetle, whose grubs destroy the roots of strawberries and other plants, while the adults spoil the flowers of roses, strawberries, and seed-turnips. The eggs are laid in the ground; the full-grown

grubs are whitish and about an inch and a half in length; after two or three years they pupate inside earthen cocoons. The adults, which are well able to fly from place to place, measure about an inch in length, are golden green above, coppery with a tint of rose beneath. Where they are likely to do

Rose-chafer (*Cetonia aurata*)
a, larva, b, cocoon

harm the adults and grubs should be collected and destroyed, and recourse may be had to remedies similar to those used against cockchafer. The 'rose-bug' of the eastern United States is another beetle (*Macrodactylus subspinosus*), a voracious pest which often appears in immense numbers and destroys the flowers of rosaceous plants.

Rosecrans, WILLIAM STARKE, an American general, was born at Kingston, Ohio, 6th September 1819, graduated at West Point in 1842, and was employed as an engineer until 1854, when he resigned, became a civil engineer, and afterwards engaged in coal-mining and the manufacture of kerosene. In 1861 he volunteered as an aide to General McClellan, won an action at Rich Mountain in July, was commissioned brigadier-general in the United States army, and succeeded McClellan as head of the Department of the Ohio, and kept Lee out of western Virginia. In 1862 he commanded a division at the siege of Corinth, and after its capture was given the command of the Army of the Mississippi; on 19th September he defeated General Sterling Price at Iuka, and on 3d and 4th October he successfully defended Corinth against Price and Van Dorn. From October 1862 to October 1863 Rosecrans was in command of the Department of the Cumberland; in the battle at Stone River (December 31 and January 2), against Bragg, he by his personal exertions converted what nearly had been a defeat into a victory, after each side had lost over 9000 men; but at Chickamauga, September 19-20, 1863, he was defeated by Bragg, with a loss of 16,179, although he held Chattanooga, and the Confederates lost 17,804 men. Rosecrans was relieved of his command by General Grant; but in 1864 he was placed over the Department of the Missouri, and repelled Price's invasion of that state. He afterwards received the brevet of major-general, and resigned from the army in 1867. In 1868-69 he was minister to Mexico, in 1881-85 a member of congress, and in 1885 appointed registrar of the U.S. treasury. He died in March 1898.

Rosemary (*Rosmarinus*), a genus of plants of the natural order Labiate, and nearly allied to Sage (*Salvia*), from which it differs in its filaments having an awl-shaped tooth, directed downwards a little above the base. Only one species is known, *R. officinalis*, an evergreen erect shrub of 4 to 8 feet high, with linear leaves, and pale bluish flowers, growing in sunny places, on rocks, old walls, &c., in the countries around the Mediterranean Sea,

and cultivated elsewhere as an ornamental and aromatic shrub. The leaves have a short whitish-gray down beneath, a penetrating camphor-like odour, and a pungent aromatic and bitter taste. They contain a large quantity of an essential oil, *Oil of Rosemary*, which is not unfrequently used as a stimulating liniment, to promote the growth of the hair, and as a perfume. *Spirit of Rosemary*, made by distillation of sprigs of rosemary with rectified spirit, is used to give a pleasant odour to lotions and liniments. Rosemary has been advantageously administered internally in cases of chronic diarrhoea, and of a relaxed state of the system.—

Rosemary (*Rosmarinus officinalis*).
(Bentley and Trimen.)

Oil of Rosemary is a principal ingredient of the perfume called *Hungary Water*. The celebrated white honey of Narbonne owes its reputation to being collected from the flowers of rosemary. In some places, by a confusion of similar names, the totally distinct plant *Costmary* (q.v.) is called Rosemary. The name Wild Rosemary is given to *Ledum palustre*, a shrub with narcotic acrid properties.

Roseneath, or **ROSNEATH**, a peninsular parish of Dumfriesshire, on the SW. shore of the Gare Loch, with a palace of the Duke of Argyll.

Rosenkranz, KARL, philosopher, a pupil of Hegel, was born at Magdeburg on 23d April 1805, studied at Berlin, Halle, and Heidelberg, taught at Halle as *privat-docent* (1828), and as professor of Philosophy (1831), in 1833 was called to the chair of Philosophy in Königsberg, and there he died, blind, on 14th June 1879. He was a man of wide culture and a voluminous writer, his works including *Encyclopadie der theologischen Wissenschaften* (2d ed. 1845), *Psychologie* (3d ed. 1863), *Kritische Erläuterungen des Hegelschen Systems* (1840), criticisms of Schleiermacher's (1836) and Strauss's Doctrines of Belief (1845), *Meine Reform des Hegelschen Systems* (1852) and *Wissenschaft der logischen Idee* (1858-59) in philosophy, and books on the History of Poetry, *Diderot's Leben und Werke* (1866), *Leben Hegels* (1844), *Goethe und seine Werke* (2d ed. 1856) in literature. He also edited, with Schubert, *Kant's Werke* (12 vols. 1838-40).

See his autobiographical *Von Magdeburg nach Königsberg* (1873) and *Life* by Quabicker (1879).

Rose-noble. See NOBLE.

Rose of Jericho (*Anastatica hierochuntica*), a plant of the Cruciferae, which grows in the sandy

deserts of Arabia, and on rubbish, the roofs of houses, and other such situations in Syria and other parts of the East. It is a small, bushy, herbaceous plant, seldom more than six inches high, with small white flowers; and after it has flowered, the leaves fall off, and the branches become incurved towards the centre, so that the plant assumes an almost globular form, and in this state it is, perhaps, sometimes blown about in the desert. When the rainy season begins the branches expand again, and the pods open and let out the seeds. Numerous superstitions are connected with this plant, which is called *Rosa Maria*, or *Rose of the Virgin*. If taken up before it is quite withered the plant retains for years its hygroscopic property of contracting in drought and expanding in moisture. Other such 'resurrection plants' are *Selaginella lepidophylla* (Central America) and the scrophulariaceous *Chamaeceras intrepidus* (South Africa).

Rose of Sharon, a name given to an ornamental malvaceous plant, the *Hibiscus syriacus* (see HIBISCUS). But the Rose of Sharon of the Bible was doubtless a bulbous plant, probably a kind of narcissus.

Roseola, or **ROSE-RASH**, is a name sometimes applied to the milder varieties of Erythema (q.v.), where the eruption consists merely of a reddening of the skin, with little or no swelling. Such an eruption sometimes occurs as an early symptom in smallpox, and during the stage of reaction in cholera; it is also one of the commonest of syphilitic eruptions. But it frequently appears independently of any such disease, and is then usually an indication of some slight disorder of digestion, or of some other internal source of irritation. It usually subsides in the course of two or three days at most, and causes very little constitutional disturbance. Occasionally it is attended by slight fever and sore throat, and may then be extremely difficult to distinguish from a mild case of scarlet fever. No treatment is usually required, but a mild saline laxative (e.g. a seidlitz powder) may be administered with advantage. The name roseola is also given to rubella or German measles.

Roses. **WARS OF THE**, a disastrous dynastic struggle which desolated England during the 15th century, from the first battle of St Albans (1455) to that of Bosworth (1485). It was so called because the two factions into which the country was divided upheld the two several claims to the throne of the Houses of York and Lancaster, whose badges were the white and the red rose respectively. The Lancastrian claim to the crown came through John of Gaunt, third son of Edward III., created Duke of Lancaster in 1362, having married three years before the heiress of Henry, Duke of Lancaster. On John of Gaunt's death King Richard II. seized his lands, whereupon his son Bolingbroke, then in exile, returned to assert his rights, and, finding his cause exceedingly popular, was emboldened to claim the crown, which was granted him by the parliament after the deposition of his cousin Richard II. After the House of Lancaster had thus possessed the throne for three reigns (Henry IV., V., VI.), Richard, Duke of York, during the weakness of the last reign, began to advance, at first somewhat covertly, his claim to the throne. He was the son of Richard, Earl of Cambridge, by Anne, sister of Edmund Mortimer, the last Earl of March, and he was thus the nearest actual heir to Edward III. through his second son, Lionel, Duke of Clarence. The reigning family had become unpopular from its loss of France and its clericalism, but its strength was great in the north, where the power of the Percies was alone rivalled by that of the Nevilles. The

Yorkist strength lay chiefly in the mercantile population of the southern counties. The effect of the war was the almost complete destruction of the old nobility, the weakening of the power of the church, and an enormous increase in the power of the crown, together with the great advance of the commercial classes and the large towns, destined a few generations later to measure strength with the crown itself. In 1454 Richard was appointed Protector of the realm during Henry's insanity, and on his recovery soon after took up arms against his rival Somerset, and crushed him at the first battle of St Albans (1455). A second period of insanity again gave him the protectorship, but the king recovered in 1456. His weak attempts at reconciliation proved failures, and in 1460 the Yorkist encls of Salisbury, Warwick, and March defeated and captured the king at Northampton (1460). The Lords now decided to grant the reversion of the crown to York, passing over Prince Edward. The queen refused assent, and fled to Scotland, returning only after the death of York at Wakefield (December 30, 1460); but York's son Edward quickly gained a victory at Mortimer's Cross (1461), though Warwick was defeated by the queen's main body in the second battle of St Albans (1461). But London rallied to young Edward, and in June he was crowned at Westminster after the great victory of Towton (1461). Next year Queen Margaret again appeared in the north, but in 1464 her forces were utterly routed by Warwick's brother Montague at Hedgeley Moor and Hexham. The estrangement of Warwick and his alliance with Queen Margaret's party drove Edward IV. from England and restored Henry VI. But Edward returned in the spring of 1471, defeated (and slew) Warwick at Barnet, and next the queen at Tewkesbury. The murder of Prince Edward after the battle, and the convenient death of Henry VI. in the Tower, cleared away his two chief dangers and left him to reign in peace. The accession of Henry VII. after the death of Richard III. on Bosworth field (1485), his marriage with Elizabeth, daughter of Edward IV. (1486), and the blending of the red and white rose in the Tudor badge, marked the termination of the Wars of the Roses, although the reign of Henry, whose own title was not good, was from time to time disturbed by the pretensions of Yorkist impostors.

See Sir J. H. Ramsay, *Lancaster and York* (2 vols. 1892); Wylie, *England under Henry IV.* (4 vols. 1884-98); R. B. Mowat, *The Wars of the Roses* (1914), and the articles on the HENRIEN IV., VI., EDWARD IV., &c.

Rosetta, a town of the Nile delta, on the old Bolicic arm, 9 miles from the Mediterranean and 44 miles by rail NE. of Alexandria, which outstripped it. In the time of the Crusades it was a place of great strength; and St Louis made it the basis of his crusading operations. Sultan Beybars, after that (in 1251) founded the present city farther inland. The Arabs call it *Raschid*, believing that Haroun al-Raschid founded the whole city. Population, 17,000. A few miles to the north of the town was discovered the Rosetta Stone, which gave the first clue to the interpretation of the Hieroglyphics (q.v.).

Rose-water. See PERFUMERY.

Rose-window, a circular window with tracery, such as is shown in our illustrations to the articles AMIENS and PARIS.

Rosewood is the wood of *Cordia Gerascanthus* and *C. Sebestena*, Brazilian trees of the Boraginaceae, while *C. scabra* of Martinique also furnishes a kind. The genus yields also edible fruits and several kinds of fibre. Indian rosewood is *Dalbergia latifolia* (Leguminosae). *D. Sissoo* and *D. cultrata* also closely resemble the Brazilian rosewoods. The cellular structure of the wood is

similar in the whole of them. They are all rich in resinous colouring matter, and all except *D. latifolia*, which is slightly lighter, have a specific gravity ranging between .9 and 1, so that they just float in water. The South American and Indian kinds named above are all hard and durable, and take a fine polish. They are in every way excellent furniture woods, the Brazilian kinds being only more valuable because they are more beautifully figured. Indian rosewood is often elaborately carved. An inferior rosewood is brought from Honduras. The name is said to have been given because of a stinking rose like odour that the wood gives out when freshly cut.

Rosiercians. The mystery which has surrounded this brotherhood of Hermetic philosophers has afforded a wide field to romantic fiction, and has much exaggerated their own pretensions. A German pamphlet, *Fama Fraternitatis of the Mercurian Order of the Rosy Cross*, published at Cassel in 1614, advertised for the first time the existence of such an association, which then claimed an antiquity of over 120 years. From subsequent publications it is inferred that the fraternity was established, on its own showing, by Christian Rosencreutz in 1459. On this point there is no evidence outside Rosiercian manifestoes, and all that concerns the founder is of fabulous or allegorical character. If the society existed as a corporate body when the *Fama Fraternitatis* appeared, that date may be accepted as marking at least the beginning of its public history. The other documents which claim to have been issued by the Rosiercians are *Confessio Fraternitatis R.C.*, addressed to the Learned of Europe (Cassel, 1615); *Chymical Marriage of Christian Rosencreutz* (Strasbourg, 1616); *Perfect and True Preparation of the Philosophical Stone, according to the Secret of the Brotherhood of the Golden and Rosy Cross* (Breslau, 1710 - contains the unabridged laws of the order); and *Secret Symbols of the Rosiercians of the Sixteenth and Seventeenth Centuries* (Altona, 1785-88). Whether the later publications emanated from the original society it is not possible to say, but it has been supposed that associations in imitation of the fraternity, bearing its name and emblems, were formed soon after the appearance of the first manifestoes. By these documents the Rosiercians are represented as adepts in Hermetic mysteries, including metallic transmutation, power over elemental spirits, and knowledge of magical signatures—the *signatura rerum* of Paracelsus. They aimed at a general reform in arts and sciences, especially alchemy and medicine, and posed chiefly as professors of the healing art. They invited all students of nature to join them; but, as they gave no clue to their whereabouts, the manifestoes were by some regarded as a laborious hoax, an opinion which does not seem justified by a review of the entire evidence. An immense controversy took place at the time in Germany, whose literary centres became a battle-ground for rival pamphleteers on the merits of Rosiercian pretensions. The foremost defenders of the order were Michael Maier in Germany, Robert Fludd, Thomas Vaughan, and afterwards John Heydon, in England. Among its adverse critics were Andrew Libavius, who afterwards changed his standpoint, and Johann Valentin Andreae (q.v.). The authorship of the original manifestoes has, at the same time, been generally attributed to Andreae, and he certainly wrote the *Chymical Marriage of Christian Rosencreutz*. The question of the authorship offers a curious field for investigation, and has exercised the controversial skill of many ingenious critics; but no satisfactory solution has ever been reached. Rosiercians flourished in France during the period of the Revolution; there was a lodge in Mauritius

about 1794; and there are traces of such a fraternity at the beginning of the 19th century both in England and Germany. A *Societas Rosicruciana in Anglia* was formed as an offshoot of masonry by Robert Wentworth Little about 1857, which is to be distinguished from the original order, and from the Rose-cross degree in freemasonry. The latter, notwithstanding its name and symbolism, disclaims all connection with the objects and history of the alchemical brotherhood.

Among works to be consulted on the subject of the Rosicrucian mystery a first place should be given to Solomon Semler's *Impartial Collections for the History of the Rosicrucians* (Leip. 1768). De Quincey's *Rosicrucianus and Preamonius* is brilliant but misleading. A review of the whole controversy, with the documents that concern it, is contained in *The Real History of the Rosicrucians* (Lond. 1887), by A. E. Waite. A MS. *Treatise of Rosicrucian Secrets*, attributed to Dr John Dee, and preserved in the British Museum, is a forgery of the 18th century.

Roskilde. See ROESKILDE.

Roslin, a Midlothian village, near the wooded glen of the North Esk, 6½ miles S. of Edinburgh. Its castle, dating from the 14th century, was the seat of the St Clairs, Earls of Orkney from 1379 to 1471, and afterwards of Caithness, and hereditary grand master masons of Scotland from 1455 to 1736. The exquisite 'chapel,' built about 1450, is really the choir of an intended collegiate church, and is only 70 feet long, 35 broad, and 42 high. Its beauty lies not in the outline, but in the profusion of stone-carving lavished on pinnacles, niches, vaulted roof, and clustered columns, and especially on the famous 'Prentice pillar.' The building, essentially Scottish, has often been wrongly ascribed to Spanish, at any rate to foreign, masons. Much damaged by an Edinburgh mob in 1688, it was restored by the third Earl of Rosslyn, and has served since 1862 as an Episcopal church. On Roslin Moor the Scots are said to have thrice defeated the English in one day, 24th February 1303.

Rosmini. ANTONIO ROSMINI-SERBATI, one of the most original philosophers of the 19th century, was born of noble family at Roveredo, 25th March 1797. He decided for the priesthood against his parents' wishes, and began the course at Padua in 1817 and three years later his father's death gave him an ample estate. He was ordained priest in 1821, and devoted the next five years at home to study, meditation, and prayer. From 1826 to 1828 he lived mostly in Milan, thought out the rule of a new Order for the training of priests, visited Rome, gained the approval of Pius VIII. both for his special studies and for the institution of his Order, and published his *New Essay on the Origin of Ideas* (4 vols. 1830), which at once carried his name over the Catholic world. After a few years of labour at Trent, he settled in 1837 at Stresa on the western shore of Lago Maggiore, and two years later received from Gregory XVI. the formal approval of his Institute. The next few years were fruitful in volumes of philosophy, which, however, roused much opposition both from the Jesuits and from the rationalists. His dream in politics, as expressed in his *Constitution according to Social Justice* (1848), was a confederation of the states of Italy under the pope as perpetual president. For a brief period he basked in the papal favour, and was promoted by Pius IX. a cardinal's hat; while for seven weeks in 1848 he served as the envoy of Piedmont at the papal court. He followed the pope in his flight to Gaeta, but now found his mind influenced against him by Antonelli and the reactionary party, and never afterwards regained his confidence. His *Constitution and The Five*

Wounds of Holy Church (Eng. trans. ed. by Canon Liddon, 1883) were next prohibited by an irregular meeting of the Congregation of the Index called at Naples. Rosmini submitted without a word of protest, and retired to Stresa. His enemies still continued to pursue him with charges of heresy, but their malignity overshot its mark. The pope subjected all Rosmini's published works to a careful scrutiny, and finally, in 1854, the Congregation of the Index, the pope presiding, declared them to be entirely free from censure, and enjoined perpetual silence on all his accusers. But he did not long survive a triumph, dying at Stresa, 1st July 1855.

The fundamental idea of the 'Institute of the Brethren of Charity' is the principle of passivity, the aim holiness or the moral perfection of the soul. The *elective* or contemplative part of the discipline prepares for the *assumptive* or active part, whose constant aim is the well-being of others. The brethren, who include both clerical and lay members, take the three ordinary vows, but wear no distinctive dress and conform to the laws of the country in which they happen to be. The Institute of Charity was a large-minded attempt to adapt the monastic system and Catholic Christianity generally to the needs of the day, but it encountered much opposition from the obscurantist party in the church.

The foundation of Rosmini's philosophy is *being* considered as the form of the intelligence—an elemental intuition implanted by Nature herself. Intuition, an attitude rather than an activity, gives us possible objects—ideas; affirmation, things subsistent. Of ideas we may affirm (1) that they are not nothing; (2) that they are not ourselves; (3) that they have a mode of existence of their own, entirely different from that of real or subsistent things. Their two essential characteristics are *universality* and *necessity*; for real objects and sensations are always particular, instead of being universal and generic, and every object which involves no contradiction is necessarily possible. These two characteristics involve two others, infinity and eternity: the origin of the ideas comes from God, for man does not receive them from the things themselves. The one *indeterminate* and wholly universal idea is that of existence; we cannot determine the subsistence of an object until we first have the idea of it, therefore the truth of a thing is in its being. When the ideas are all fully or perfectly determined, they are called *concrete*; when they remain to a certain extent indeterminate, they are *abstract*. By the process of universalisation then we form those ideas which are completely determined; by abstraction, those which are determined only to a certain extent. It is this idea of being which makes intelligence possible. It is cognisable by itself, as otherwise there is nothing else that could make it known; the idea of being gives us itself the essence of the thing. *Being* is incorporeal, independent of space, spiritual, and therefore incorruptible and immortal. It is independent of time; as *being* in its essence is always *being*, and, as it would be a contradiction in terms for being to cease to be being, it is eternal. But since it was united to the soul in time, it must have existed before it, and be independent of it. And thus we reach an Intelligence anterior to human intelligence—an Eternal Mind. This eternal mind is God's, and therefore God exists, and his existence and the immortality of the soul remain the true foundation of morals. But *being*, as intuitively seen by nature, merely gives the certainty that God exists; it cannot make God known to us until we are illumined by a new faculty—an influx of objective light, the Light of Grace. Thus a necessary place for revelation is found in the essential limitations

of man's nature, and this revelation of God is contained in the Gospel of Jesus Christ.

Rosmini's most important works were his *New Essay on the Origin of Ideas* (1830; Eng. trans. 3 vols. 1883-84) and his *Psychology* (1846-48; Eng. trans. 3 vols. 1884-88). The *Theosophy* (5 vols. 1859-74) was left unfinished. A complete Bibliography of his writings, ninety-nine in number, is prefixed by Davidson to his translation with introduction (1882) of the *Systema Filosofico* (1845). See the studies by Paoli (1884-86), and Lockhart (1886); the translation with introduction by Lockhart of the *Sketch of Modern Philosophies*; and the Lives by Pagani (1907) and Palhories (1908).

Rosoglio, a variety of liqueur, made in Italy, flavoured with flowers or fruits, especially orange-blossoms.

Ross, a Celtic word, meaning a headland, occurring as the name or part of the name of many places in the British Islands, and in other parts of Europe, as Roslin, Culross, Dunrossness, Montrose, Ardrossan.

Ross, a market town in Herefordshire, is finely situated on the left bank of the Wye, 14 miles SSE. of Hereford. In the parish church (1316), whose 'heaven-directed spire' is 208 feet high, is buried John Kyrie (q.v.), celebrated by Pope as the 'Man of Ross.' The town trades in cider, corn, malt, and wool. Pop. 5000.—For Ross in Leinster, see NEW ROSS. 'The Rosses' is a wild district in the west of Donegal.

ROSS, SIR JOHN, Arctic voyager, born June 24, 1777, was a son of the minister of luth, Wigtonshire, and was little more than nine years old when he entered the navy, serving with distinction in the French wars. His most important services were rendered in the Arctic regions, whither in 1818 he proceeded with Parry as his second in command; the objects of the expedition were to explore Baffin Bay and attempt a North-west Passage. Ross published the results of his investigations in *A Voyage of Discovery* (1819). In May 1829 he commanded a fresh expedition to the Arctic regions (fitted out by Sir Felix Booth), and discovered the peninsula of 'Boothia Felix.' Ross received, on his return in 1833, the honour of knighthood. The results of this expedition were written down in *Narrative of a Second Voyage in Search of a North-west Passage* (1835). He made yet another voyage to the Polar regions—an unsuccessful attempt to find Sir John Franklin, in 1850. Ross wrote *Memoirs and Correspondence of Admiral Lord de Saumarez* (2 vols. 1838), a *Treatise on Navigation by Steam* (1828), and other works. He died in London, August 30, 1856.

SIR JAMES CLARK ROSS, his nephew, also distinguished himself as an Arctic navigator. He was born in London, April 15, 1800, entered the navy in his twelfth year, accompanied Sir John in his first and second Polar voyages, and in the interval between visited the same regions with Parry in his expeditions. He discovered in 1831 the North magnetic pole, and on his return was rewarded with a post-captaincy. After being employed by the Admiralty in a magnetic survey of Great Britain and Ireland, he was placed in command of the *Erebus* and *Terror* on an expedition to the Antarctic seas (1839), and approached within 160 miles of the South magnetic pole. He was knighted after his return home in 1843; and in 1847 published *Voyage of Discovery in Southern Regions, 1839-43* (2 vols. 1847). In 1848 he made a voyage in the *Enterprise* to Baffin Bay in search of Sir John Franklin. He died at Aylesbury, April 3, 1862. See Mackinder, *Ross and the Antarctic* (1892).

ROSS, SIR RONALD, born in 1857 at Alnora in India, studied at Bartholomew's, and was in the Indian Medical Service from 1881 to 1899. From 1892 he gave himself to the special study of

the cause and prevention of malaria, and worked out the life-history of the parasite. See his articles GNAT and MALARIA in this work. He was professor of Tropical Medicine at Liverpool. The Ross Institute for Tropical Diseases at Putney Heath (opened 1926) was founded in his honour. Besides his writings on malaria, he is author of poems, a novel, mathematical works, and *Memoirs* (1923).

Rossall College, a large public school on the coast of Lancashire, 2½ miles SSW. of Fleetwood, was founded in 1844 for the education of the sons of clergymen and others. See the *Jubilee Sketch* by Canon Beechey (1894).

Ross and Cromarty, a Highland county, the third largest in Scotland, extends from the North Sea to the Atlantic, and is bounded N. by Sutherland, S. by Invernesshire. In 1890-91 it was finally formed into a single county by the boundary commissioners, who also added to it the small Ferintosh (detached) district of Nairnshire, and a much smaller fragment from Invernesshire. Its mainland portion measures 75 by 67 miles, and the total area is 1,977,248 acres or 3089 sq. m., of which 103 are water and 736 belong to a dozen islands—the Lewis, Tanera, Ewe, &c. The east coast is indented by the Dornoch, Cromarty, and Moray Firths; the west coast by eight sea-lochs (Broom, Grunard, Torridon, Carron, &c.). The chief of the innumerable streams are the Oykel, Aness, and Conon; the Falls of Glomach, on a head-water of the Elchaig, in the SW. are 370 feet high; and beautiful Loch Maree is the largest of nearly a hundred good-sized fresh-water lakes. Mam Sodhail (3862 feet), on the Invernesshire border, is the largest of more than thirty summits exceeding 3200 feet above sea-level, others being Ben Dearg (3547), Benmore (3505), Ben Wyvis (3429), and Ben Attow (3383). The high grounds afford good pasture, and systematic sheep-farming dates from about 1764. It reached its zenith during 1860-70, when 400,000 sheep were grazed in the county. The glens and low grounds in the more favoured portions have a fertile soil, which, with the fine climate, especially in Easter Ross, bears crops of superior quality. More than half the county, however, is occupied by mountain and heath land. Whisky is distilled, and the sea fisheries are valuable. Montrose was defeated at Invercharron (1650), and a small Jacobite force in Glenshiel (1718). Sir Thomas Urquhart, Lord Lovat, Hugh Miller, Sir Roderick Murchison, and Hector Macdonald were natives. The chief places are Dingwall, Tain, Stornoway, Fortrose, Cromarty, Strathpeffer, and Invergordon; the county with Invernesshire returns three members to parliament. Pop. (1801) 56,318; (1851) 82,707; (1921) 70,818. See CROMARTY, DINGWALL, LEWIS, MAREE, HEBRIDES, &c.; W. J. Watson, *Place Names of Ross and Cromarty* (1904), and two books (1924) by the same author on county history and geology.

Rossano, a city and archiepiscopal see of Southern Italy, 24 m. NNE. of Cosenza. It was the ancient Roscianum. Totila took it in 548. In the 14th century it became a principality for the family of De Baix, but was finally united with the crown of Naples in 1558. St. Nilus was born here in the 11th century. Pop. 16,000.

Rossbach, a village in Prussian Saxony, 22 miles W. by S. of Leipzig and 9 SW. of Merseburg, is celebrated for the victory of the Prussians under Frederick the Great (q.v.) over the combined French and Austrian armies on 5th November 1757. The 'ront of Rossbach' remained for a long time a term of reproach in the French army. The Prussians lost 540 killed and wounded, while the loss of the allies was more than 2700 killed and

wounded, 5000 prisoners (among whom were 5 generals and 300 officers), and nearly 70 cannon.

Ross Barrier, an ice barrier, almost entirely afloat, situated about the 78th parallel of latitude in the Ross Quadrant of Antarctica (q.v.).

Ross Dependency, by Order in Council of 1923, consists of all lands south of 60° S. lat. between 160° E. and 150° W. long. (South Victoria Land, the Ross Barrier, Edward VII. Land). Its government is vested in the Governor-general of New Zealand.

Rossc, WILLIAM PARSONS, third EARL OF, an astronomer, was born in York on 17th June 1800, and educated at Trinity College, Dublin, and Magdalen College, Oxford, where he graduated first-class in Mathematics in 1822. During the life of his father he sat in the House of Commons as Lord Oxmantown, representing King's County from 1821 to 1834; he succeeded to the peerage in 1841, and was elected a representative peer for Ireland in 1845. As early as 1826 he had begun to make experiments in the construction of fluid lenses; but he subsequently devoted his powers to the construction of a speculum for the reflecting telescope. Certain defects had hitherto baffled opticians—namely, spherical aberration and absorption of light by specula, and in casting specula of large size cracking and warping of the surface on cooling; but Lord Rosse succeeded in obviating the last defect, and in counteracting in great part the other two. He began the construction of his great reflecting telescope in 1845; it weighed in all 12 tons, and was mounted in his park at Parsonstown at a cost of £30,000. The first addition to astronomical knowledge made by this telescope was the resolution of certain nebulae into groups of stars; next came the discovery of numerous binary and triary stars, and a description of the moon's surface. P.R.S. in 1848-54, he died 31st October 1867.—The Hon. Sir Charles Algernon Parsons, his fourth son (born 1854), educated at St John's, Cambridge, developed the steam turbine for the generation of electricity and the propulsion of vessels, naval and mercantile, and designed the earliest steam-turbine to be made commercially successful (see SHIPBUILDING, STEAM-TURBINE). He became proprietor and director of several great electrical and engineering works, and in 1919 was elected president of the British Association.

Rossendale, a parliamentary borough (1918) of north-east Lancashire, consisting of Bacup (q.v.), Haslington (q.v.), and Rawtenstall (q.v.).

Rossetti, CHRISTINA GEORGINA, younger daughter of Gabriele and Frances Rossetti, was born in Charlotte Street, Portland Place, London, on 5th December 1830. She was brought up entirely at home under her mother's tuition, as a member of the Anglican Church. She began writing verse in early girlhood. Before she was seventeen a little volume of her poetry was privately printed by her maternal grandfather, Gaetano Polidori, who kept a printing press for his own convenience at his residence in London. Her publications are *Goblin-Market and other Poems* (1862), *The Prince's Progress and other Poems* (1866), *Commonplace and other Stories* (in prose, 1870), *Singsong* (1872), *A Pageant and other Poems* (1881), *Verses* (1893), and a few devotional volumes, among them *Time Flies, a Reading Diary* (with verses, 1885), and *The Face of the Deep* (on the Apocalypse, 1892). Most of her poems were re-issued in 1890; and after her death her brother William undertook a complete edition of her works. Miss Rossetti, whose health was weak, died 29th December 1894. She had lived a very secluded life, divided between devoted attention to her mother (who died at a

very advanced age in 1886), and earnest religious thought and practice. In direct poetic gift and intrinsic quality of poetry she may be regarded as fully equal to her brother Dante Gabriel, although the outcome is of a less conspicuous kind. Her poems have a singular degree of grace, delicacy, and spontaneity, deep in feeling, sensitive and certain in touch, and marked by great purity of emotional thought, and by an unflinching instinct of style. Several of her lyrics have been set to music, and cantatas for two of the longer poems—*Goblin-Market* and *Songs in a Cornfield*—were composed by Aguilair and Macfarren. See her *Life* by Mac-kenzie Bell (1898).

Rossetti, DANTE GABRIEL (or properly Gabriel Charles Dante), elder son of Gabriel Rossetti (q.v.), was born in Charlotte Street, Portland Place, London, on 12th May 1828. He was educated in King's College School, London; but, having from his earliest years evinced a wish to become a painter, he was taken from school in 1843 and commenced the study of art, entering soon afterwards the antique school of the Royal Academy. Here he associated with the young painters John Everett Millais and William Holman Hunt, and the sculptor Thomas Woolner; along with these three he founded the so-called Pre-Raphaelite Brotherhood, which was completed by the addition of three other members. The chief incentive to the foundation of this society, and of the school of art which it initiated, was the distaste and disrespect felt by the youthful artists for the poverty-stricken conceptions and slurred execution which marked most of the art then current in England, mingled with a sincere and reverent delight in those qualities of genuine and spontaneous invention, lofty feeling, and patient handiwork, which had been developed by the European schools of art preceding the culmination of Raphael and his followers. A natural result of this frame of mind was a disposition to realise objective details to the utmost, with a view to the thorough authenticity of the visible means through which ideas are conveyed; but it was a mistake of some observers, who noticed a scrupulous exactness and sometimes a plethora of details, to suppose that the main concern of the associated artists was really with the details and not with the ideas. The English Pre-Raphaelites wished to exhibit true and high ideas through the medium of true and rightly elaborated details. Two other mistakes have been frequently repeated concerning these artists: first, that they were an offshoot of the 'Tractarian' movement, guided by religious pietism; and second, that they were set going by Ruskin. Rossetti's earliest oil-picture, exhibited in 1849, was 'The Girlhood of Mary Virgin,' his next (1850), now in the National Gallery, 'The Annunciation.' After this he withdrew from exhibiting almost entirely, and his art developed through other phases, in which the sense of human beauty, intensity of abstract expression, and richness of colour were leading elements. He produced numerous water-colours of a legendary or romantic cast, several of them being from the poems of Dante, others from the Arthurian tradition. Among his principal oil-pictures are the Triptych for Llandaff Cathedral, of the 'Infant Christ adored by a Shepherd and a King,' 'The Beloved' (the Bride of the Canticles), 'Dante's Dream' (now in the Walker Gallery, Liverpool), 'Beata Beatrix' (National Gallery), 'Pandora,' 'Proserpine,' 'The Blessed Damozel' (from one of his own poems), 'The Roman Widow,' 'La Ghirlandata,' 'Venus Astarte,' 'The Day-dream.' He designed several large compositions, such as the 'Magdalene at the door of Simon the Pharisee,' 'Giotto Painting Dante's Portrait,' 'Cassandra,' and the 'Boat of Love' (from a sonnet by Dante); but these he

failed to carry out as pictures on an adequate scale, partly owing to his receiving constant commissions to execute smaller works, consisting mostly of female half-figures ideal in invention or feeling, and executed in life-size. The early studies of Rossetti in art had not been so steady or systematic as might have been wished. Afterwards, beginning in 1848, he had the advantage of some friendly training from his constant intimate, Ford Madox Brown, the historical painter; but, notwithstanding his passionate impulse as an inventive artist, and his impressive realisation of beauty in countenance and colour, some shortcomings in severe draughtsmanship and in technical method, and some degree of mannerism in form and treatment, have often, and not unjustly, been laid to his charge. Rossetti began writing poetry about the same time that he took definitely to the study of painting. Besides some juvenile work, and some translations from the German (that of *Henry the Leper*, by the mediæval poet, Hartmann von der Aue, is preserved), he executed a number of translations from Dante and other Italians, published in 1861 as *The Early Italian Poets*, and again in 1874 as *Dante and his Circle*. Two of his best-known original poems, *The Portrait* and *The Blessed Damsel*, were written in his nineteenth year, and many others followed. These were about to be published in 1862 in a volume (some of them having been previously printed in magazines—chiefly in *The Germ*, 1850, and *The Oxford and Cambridge Magazine*, 1856), but a domestic calamity intervened, and all idea of a publication was set aside for some years. Rossetti had fallen in love towards 1851 with a very beautiful girl, a dressmaker's assistant, named Elizabeth Eleanor Siddal; he married her in 1860, but she died suddenly in February 1862. In the first impulse of desperation he buried his MSS. in her coffin. In 1869 he thought fit to recover them, and in 1870 he issued his volume named *Poems*, containing the bulk of those compositions and several others written not long before the date of publication. This volume was a success with poetical readers, and was reviewed with great admiration and even enthusiasm by some leading critics. Late in 1871, however, Robert Buchanan, writing in the *Contemporary Review* under the pseudonym of Thomas Maitland, attacked the book on literary, and more especially on moral grounds, and soon afterwards he republished his article, *The Fleckly School of Poetry*, as a pamphlet. Rossetti was now in a depressed state of health, suffering much from insomnia, from an ailment of the throat as a palliative, and from weakened eyesight (he often thought he would become blind, as his father had very nearly been). The literary detraction, conspiring with physical malady, produced a strong and exaggerated effect upon him; and from about the middle of 1872 he became morbidly sensitive and gloomy, and very reclusive in his habits of life, though his naturally strong sense, and his turn of mind, in which a good deal of humour and practicality was blended with idealism, continued to form a substantial counterbalance. In 1881 he published a second volume of poems named *Ballads and Sonnets* (containing some of his finest work, 'Rose Mary,' 'The White Ship,' 'The King's Tragedy,' and the completed sonnet-sequence, 'The House of Life'), and at the same time he re-issued, with some omissions and interpolations, the *Poems* of 1870. His health was by this time extremely shattered. A touch of paralysis affected him towards the end of 1881, and, retiring in the hope of some improvement to Birchington-on-Sea, near Margate, he died there of uræmia on 9th April 1882. The poetry of Rossetti is intense in feeling, exalted in tone, highly individual in personal gift,

picturesque and sometimes pictorial in treatment, and elaborately wrought in literary form. These characteristics are sometimes made consistent with simplicity, but more generally with subtlety, of emotion or of thought. As in his paintings, there is a strong mediæval tendency. It is now generally allowed that Buchanan's charges of immorality against the writings were wide of the mark; indeed, he himself admitted and proclaimed as much. Rossetti was intimate at one or other period of his life with many of the best men of the day. In politics he took no part. His religious views were vague—at times negative enough; but he had a strong sense of reverence, and a tendency to superstition rather than distinct faith. His portrait, a pencil-drawing executed by himself towards the age of eighteen, is in the National Portrait Gallery. He was generous, untrifling, warm-tempered, and very natural and unaffected in manner.

See William Sharp, *Dante Gabriel Rossetti, a Record and Study* (1882); Hall Caine, *Recollections* (1882); Joseph Knight, *Life of Dante Gabriel Rossetti* (1887); the *Portfolio* monograph by F. G. Stephens (1894); the book by H. C. Marillier (3d ed. 1904); the *Recollections* of him by H. T. Dunn (1903); the *Life* by A. C. Benson (1904); the article by Watts-Dunton in the *Encyclopædia Britannica*; and the Memoir, Letters, and Family Papers (1895-1905) by his brother William Michael (1829-1919), author of the above article, who published annotated editions of several poems, including Shelley and D. G. Rossetti (2 vols. 1886), books on art and *Some Reminiscences* (1906). See PRE-RAPHAELITISM.

ROSSETTI, GABRIELE, Italian poet, man of letters, and Dante critic, was born in 1783 at Vasto, in Abruzzo Citeriore, then forming part of the kingdom of Naples. His father, Nicola Rossetti, was engaged in the iron-trade of the district; his mother was Maria Francesca Pietrocola. The parents were not in easy circumstances, and had a large family: besides Gabriele, two of the sons attained some eminence, Andrea becoming a canon in the church, and Domenico being well reputed in letters and antiquities. Gabriele gave early signs of more than common ability, and was placed by the local grandee, the Marchese del Vasto, to study in the university of Naples. The boyhood and youth of Rossetti passed in a period of great political commotion, consequent upon the revolutionary and imperial wars of France. The Bourbon king of Naples, Ferdinand I., was ousted by the Parthenopean Republic, and again by King Joseph, the brother of Napoleon, and his successor King Joachim (Murat), the emperor's brother-in-law, and Ferdinand had to retire to Sicily. Rossetti obtained an appointment as Curator of Ancient Bronzes in the Museum of Naples, and also as librettist to the operatic theatre of San Carlo: he wrote the libretto of an opera, *Giulio Sabino*, was well received at the court of the Napoleonic sovereigns, and in 1813 acted as a member of the provisional government sent to Rome by Murat. After the restoration of Ferdinand to Naples in 1815 he continued his connection with liberal politicians, and joined the widely-diffused secret society of the Carbonari. In 1820 a military uprising compelled King Ferdinand to grant a constitution on the model of that which had recently been established in Spain. Rossetti saluted its advent in one of his most celebrated odes, beginning 'Sei pur bella cogli astri sul crine' ('Beautiful indeed art thou, with the stars in thine hair'). The good faith of the king was highly dubious from the first, and in 1821 he abrogated the constitution, and put it down with the aid of Austrian troops. The constitutionalists were proscribed and persecuted, Rossetti among them. Two verses in one of his lyrics are said to have given

especial offence to the king—'Chè i Sandi ed i Luveli Non sono morti ancor' ('For Sands and Louvels are not yet dead'—alluding to the assassination of Kotzebue and of the Duc de Berri). Rossetti had to escape from Naples with the kindly connivance of the British admiral, Sir Graham Moore, who shipped him off to Malta in the disguise of a British naval officer. In Malta he was treated with great liberality and distinction by the governor, Hookham Frere; and towards 1824 he came over to London, with good recommendations, to follow the career of a teacher of Italian. In 1826 he married Frances Mary Lavinia Polidori, daughter of a Tuscan father and English mother; soon afterwards he was elected professor of Italian in King's College, London. They had four children: (1) Maria Francesca, born 1827, died 1876 (author of *A Shadow of Dante*, &c.); (2) Gabriel Charles Dante, otherwise Dante Gabriel (q.v.); (3) William Michael, 1829-1919 (critical writer, and editor of *Shelley*); (4) Christina Georgina (q.v.). In London Rossetti lived a studious, laborious, and honourable life, greatly respected by his pupils, and by Italian residents and visitors; he was a man of strong and steady affections and vivacious temperament, earnest and single-minded in all his pursuits. In politics he was a vigorous Liberal, but more inclined to a constitutional monarchy than a republic; in religion he was mainly a freethinker, but tending in his later years towards an undogmatic form of Christianity. Though totally opposed to the papal system and pretensions, he would not openly abjure, in a Protestant country, the Roman Catholic creed of his fathers. His health began to fail towards 1842, and his sight became dim, one eye being wholly lost. After some attacks of a paralytic character he died in Albany Street, London, on 26th April 1854. Besides some poems published in Italy, Rossetti produced the following works: *Dante*, *Commedia* (the *Inferno* only was published), with a commentary aiming to show that the poem is chiefly political and anti-papal in its inner meaning (1826); *Lo Spirito Anti-papale che produsse la Riforma* ('The Anti-papal spirit which produced the Reformation'—an English translation also was published, reinforcing and greatly extending the same general views (1832); *Idillio e l'Uomo, Salterio* ('God and Man, a Psalter'), poems (1833); *Il Mistero dell' Amor Platónico del Medio Evo* ('The Mysterious Platonic Love of the Middle Ages'), 5 vols., a book of daring and subtle speculation tending to develop the analogy between many illustrious writers as forming a secret society of anti-Catholic thought, and the doctrines of Gnosticism and freemasonry (1840); this book was printed and prepared for publication, but withheld as likely to be deemed rash and subversive; *La Beatrice di Dante*, contending that Dante's Beatrice was a symbolic personage, not a real woman (1842); *Il Veggente in Solitudine* ('The Seer in Solitude'), a speculative and partly autobiographical poem (1846); it circulated largely, though clandestinely, in Italy, and a medal of Rossetti was struck there in commemoration; *Versi* (miscellaneous poems), 1847; *L'Arpa Evangelica* ('The Evangelic Harp'), religious poems (1852). The views of Rossetti regarding Dante, along with Petrarca and many other Italian authors, excited a great deal of controversy. His memory is much revered in his native place, where the house of his birth has been bought as public property, and a theatre and the chief square have been named after him.

The work of Aroux, entitled *Dante Héritique, Révolutionnaire, et Socialiste* (1854), is founded chiefly on Rossetti's researches, which it presents in an exaggerated form.

Rossi, PELLEGRINO, was born of a noble family at Carrara, 13th July 1787. He studied at Bologna, and was made professor of Law there at twenty-five. Exiled after the fall of Murat, he obtained a chair at Geneva, and there wrote his *Traité de Droit Pénal*. In 1833 Louis-Philippe called him to Paris, and appointed him professor of Political Economy at the Collège de France. For his *Cours de Droit Constitutionnel* (1836) he was naturalised and made a member of the Chamber of Peers. He was sent to Rome as ambassador in 1845, and there witnessed all the events of 1848, having again become an Italian subject after the fall of Louis-Philippe. When called to the ministry by Pius IX. Rossi strove to oppose the party favourable to the House of Savoy, and devised an alliance with Naples, his object being a confederation of Italian princes with the pope as president. This roused the hatred of the Romans, and Rossi was stabbed to death by an unknown hand on the 15th November 1848.

Rossini, GIOACCHINO ANTONIO, Italian operatic composer, was born at Pesaro, on the Adriatic, February 29, 1792, and was the only child of Giuseppe Rossini, town trumpeter and inspector of slaughter-houses, from whom he inherited his brightness and humour. From the age of seven he studied music and singing at Bologna under various masters, till in 1807, after having appeared as conductor of the local *Accademia dei Concordi*, he entered the Bologna *Liceo*, or conservatorium. He soon became known in neighbouring towns as accompanist at the theatres, travelling along with his father, now a horn-player. Numerous operatic works, mostly successful, were written for the theatres at Venice, Bologna, Rome, &c. In 1813 *Tancredi*, at Venice, created the wildest excitement, which soon spread over Italy. On 5th February 1816 was brought out at the Argentine theatre in Rome *Il Barbiere di Siviglia*, founded on Beaumarchais's play, and written in thirteen days. From the predilection of the Romans for the aged Paesello, who had written an opera on the same play, and from a series of ludicrous accidents, it resulted on the first night in a complete fiasco; but next night, after the first act had been fairly heard, the public in their enthusiasm proceeded to Rossini's house, and conducted him to the theatre in triumph; and its popularity increased with each succeeding representation. Of all his works, it is the prospect of most lasting vitality. From 1815 to 1823 he is said to have completed twenty operas, including *Otello* (1816), *La Gazza Ladra* (1817), *Mosè in Egitto* (1818), and *Semiramide* (1823). In 1821 he married Isabella Colbran, who had sung frequently in his operas, and the two visited Vienna, Paris, and London, meeting everywhere with the most cordial reception. For eighteen months Rossini discharged the duties of director of the Théâtre Italien at Paris. Finally, there appeared at the Académie, on 3d August 1829, his greatest work, *Guillaume Tell*, conceived and written in a dramatic style entirely different from and superior to that of his Italian operas. Its success was immediate and immense, but, chiefly owing to the wretched libretto, not lasting. From this period till his death he produced nothing except the *Stabat Mater* (1841) containing music little in keeping with the religious nature of the subject, and some charming trifles for the piano first published in 1919 and arranged as a ballet with the title *La Boutique Fantasque*. In 1836 he retired to Bologna where he raised the *Liceo* to a high position as a school of music, and in 1847 revolutionary disturbances drove him to Florence. In 1855 he returned to Paris, and in his villa at Passy became one of the most noted and attractive personalities of the capital, where he died 13th

November 1868. As a composer, Rossini undoubtedly had an inexhaustible faculty for creating tuneful melodies, which, however, often hover perilously near the commonplace. He effected certain improvements in opera, putting an end to the licence granted to singers to embellish at will the melodic line, and writing all the ornamentation himself. *Il Barbiere* abounds in gaiety and sparkling humour, but Rossini was singularly lacking in self-criticism, and it is very doubtful whether his work, with its florid roulades and insignificant orchestral accompaniments, will ever emerge from its present oblivion.

See the *Lite* by Stendhal (1824), in which the author exposes some of his own æsthetic theories; two books on Rossini by H. S. Edwards (1869, 1881); works by Azevedo and Dauriac; chapters in the studies on opera by Strafford and Aphorix. See **OPERA**.

Rossitten, on the Kurische Nehrung, a strip of sandy dunes between the Kurisches Haff and the Baltic, seat of the *Vogelwarte* of the German Ornithological Society, where notable work has been done in investigating the migration of birds.

Rosslare, a port of County Wexford, 9 miles S.E. of Wexford, has a harbour with a great break water, from which steamers cross to Fishguard.

Rostand, EDMOND (1868-1918), French poetic dramatist, produced his first play, *Les Romanesques* in 1894, which was followed by *La Princesse Lointaine* (1896), *La Samaritaine* (1897), and his masterpiece *Cyrano de Bergerac* (1897), where brilliant imagination is combined with poetic fancy. Later plays were: *L'Aiglon* (1900), which deals with the Duc de Reichstadt, the son of Napoleon I.; the farinard drama *Chantecler* (1910), in which the poet expresses the joy in work and in being humbly useful; and *La Dernière Nuit de Don Juan* (1918). In the 20th century Rostand is somewhat of a paradox, a dramatist with a keen sense of the theatre, who writes in verse—and verse of an exquisite clarity and charm. Both Rostand and his wife, Rosemonde Gérard, wrote poems.

Rostock, the most important town of Mecklenburg-Schwerin, and one of the busiest ports on the Baltic, stands on the Warnow, 7 miles from its mouth and 60 miles by rail N.E. of Schwerin. It has busy fairs for wool, horses, and cattle; imports coal, wine, herrings, petroleum, groceries, timber, &c.; exports grain, wool, flax, and cattle; owns a large mercantile fleet, and includes Warnemünde, at the mouth of the river. The industries are very varied, the most important being shipbuilding, the making of machinery, tanning, brewing, distilling, the manufacture of hats, tobacco, &c. The university, founded in 1418, but rebuilt in 1867, is the chief of the public institutions; it has a great library, an observatory, and an experimental agricultural colony. Amongst the churches are St. Mary's (1398-1472), one of the finest Gothic churches of north Germany, with late Renaissance interior, in which is a monument of Grotius; and St. Peter's, with a tower 414 feet high. The former ducal palace (1702) and the 14th-century Gothic town-house deserve mention. Rostock has also: a municipal museum, a geological institute, and a handsome public park. The statue of Blücher, a native, adorns one of the squares. Pop. (1875) 34,172; (1910) 65,377; (1925) 71,355. Rostock, an ancient Slav town, was burned to the ground by Waldemar of Denmark in 1161. In 1314 it came to Mecklenburg. About this time it enjoyed great repute as a powerful member of the Hanseatic League, and secured important rights of self-government. It still possessed, under the Grand Dukes, a thoroughly republican municipal constitution,

and formed a separate estate in the Mecklenburg Assembly.

Rostopchine, COUNT FEODOR VASSILIEVICH (1763-1826), Russian general, was born in the government of Orel, was appointed governor of Moscow by the Emperor Alexander in May 1812. He it was, according to the French writers, who planned and began with his own hand the burning of Moscow. But in 1823 he published *La Vérité sur l'Incendie de Moscou* (Paris, 1823), in which he rebuts the charge, affirming that this action was due in part to a few of the inhabitants, and in part to the violence and negligence of the French. Nevertheless, he subsequently recalled this denial and admitted his share in the burning, in that he at least set fire to his own mansion-house. See *Lives* by Schmitzler (Paris, 1863) and by Ségur (Paris, 1872).

Rostov, (1) a town of south Russia, stands at the head of the delta of the Don and on the railway (1875) from Moscow to the Caucasus. It owes its origin to the foundation of a fortress in 1761, since which time the progress of the town, owing to its advantageous situation, has been remarkable. Pop. (1881) 44,500; (1910) 121,300; (1920) 176,770. It exports wheat, linen, and wool, besides other grain. The manufactures have grown rapidly, the principal articles produced being flour, ropes, tobacco, macaroni, soap, and leather: but there are also shipbuilding yards, wool-cleansing establishments, and caviare-factories. Important fairs are held. In 1918 the Russian university of Warsaw was transplanted to Rostov, and reorganised as the University of the Don.—(2) One of the oldest towns of Russia, stands on a small lake, 129 miles by rail N.N.E. of Moscow, and has celebrated market gardens, a large fair, an extensive trade, tallow-works, and coarse linen manufactures. Pop. 15,000.

Roswitha, or HROTHSWITHA, German nun, poetess and dramatist, was born probably about 930 and died about 1002. Her literary talent was carefully developed in the convent of Gandersheim, near Göttingen, and her works have something more than a mere historical value. They include four epics, six legends mainly on the saints, and six dramas. The dramas are skillfully written and are in emulation of Terence, though with a definite moral end. There are several English translations. See articles **DRAMA** and **MYSTERIES AND MIRACLE PLAYS**.

Rosyth, a dockyard closed in 1925, in the burgh of Dunfermline (q.v.).

Rot. See **FLUKE**, **DRY ROT**, **PLANTS (Diseases)**.

Rotary, a movement started in Chicago by a lawyer, Mr Paul Harris, in 1905, spread to Britain in 1911, and has now reached other parts of the world. A rotary club is an association of business men, each member of a different occupation, who meet regularly for discussion and social intercourse, thereby getting to understand one another's points of view, increasing their mutual helpfulness, and raising the standard of business ethics. 'Service, not self' expresses its spirit. See Thomas Stephenson, *Rotary: its History, Interpretation, and Possibilities* (1915).

Rotation. When all points of a body are moving with the same Velocity (q.v.) the motion is one of pure translation, and is easy to comprehend. When, however, this condition is not fulfilled there must exist the kind of motion known as rotation. As simple examples, take the whirling of a flywheel or the motion of the hands of a watch. In such cases we readily see that there is, in the rotating body, a row of points which does not itself move. This row of points is called the axis of rotation, and every other point in the body

describes a circle about it. To specify the motion completely we must know not only the position of this axis, but also the rate of rotation and the sense, clockwise or counterclockwise, with which the body is rotating about the axis. The rate of rotation may be measured by the number of revolutions made in a chosen time. It is more scientific, however, to measure it in terms of the angular speed. If the body is rotating uniformly the angular speed is the angle described in unit time by any plane drawn in the body parallel to or containing the axis of rotation: e.g. with the unit of time one sidereal day, the earth's angular speed about its axis is 2π or 360° ; but with the second as the unit of time the angular speed is a quarter of a minute of arc, or .000073 in radians.

In a simple geometric way a given rotation may be represented by a directed line taken of length numerically equal to the angular speed, and drawn along the axis of rotation in that direction which is related to the sense of rotation exactly as the to-and-fro motion of a right-handed screw is to the rotational motion of the screw. Such a directed quantity of definite length and of definite line position is called by Clifford a *rotor*. It is a Vector (q.v.) under the restriction that its lie in space is limited to a particular straight line.

So long as the axis of rotation is fixed with reference to lines which appear steady to us, there is no difficulty in apprehending the character of the motion. Take, however, the case of a carriage wheel or boy's hoop rolling along the road. Here we may regard the wheel as rotating about an axis drawn through the centre, while the axis is at the same time travelling forward with a definite linear speed—i.e. we may regard the motion as a combination of translation and rotation. In this particular case we may, however, represent the motion at each instant as one of pure rotation about an axis coinciding with the instantaneous line of contact of the wheel with the road. For, with rolling and no slipping, this line of contact with the road is for the moment at rest. And it is almost self-evident that, if at any instant there exists in rigid connection with a moving body an axis momentarily at rest, the instantaneous motion must be of the character of a rotation about this axis. The above is a simple example of what holds generally in uniplanar motion i.e. motion in which every point of the body moves in a plane perpendicular to a fixed direction. The general theorem is that any uniplanar displacement whatever (which is not a pure translation) can be effected by a pure rotation about a determinate axis. Since any given motion may be regarded as consisting of a succession of displacements, it follows that any such uniplanar motion can be effected by a succession of rotations about instantaneous axes whose successive positions in space and in the body are determinate.

In uniplanar motions generally it is clear that the instantaneous axis of rotation, however much it may move, both in space and in the body, must always remain parallel to the same direction. If discontinuous motion be excluded—and all natural motions are continuous—this instantaneous axis will pass continuously from position to position. It will trace out cylindrical surfaces, one in space and one in the body; and at any given instant these surfaces will touch along the line which is for the moment the instantaneous axis. It is not difficult to show that the complete motion of the body may be represented by the rolling of one of these surfaces upon the other. In the simple case of the carriage wheel the rolling surfaces are evidently the circumference of the wheel and the plane of the road. These theorems in uniplanar motion have many interesting applications in the

kinematics of machinery (see Minchin's *Uniplanar Kinematics*, Clarendon Press, 1882).

If the motion is not uniplanar it is no longer possible in general to represent it by a succession of pure rotations. There is, however, a very remarkable theorem, which can be proved without difficulty, but which is hard of apprehension and even of acceptance. It is that after any displacement whatever of a body in space there is, in the body or rigidly connected with it, a line of points which is simply shifted along its own line in space. The whole displacement may then be effected by means of a sliding along this line together with a pure rotation about it—in other words, by a definite screw motion with reference to this line as axis (see SCREW). Even in the simpler case, when by fixing one point of a body we quite exclude translation, it is not easy to grasp the significance of the fact that after any displacement there is always one row of points which occupy exactly the same positions as before the displacement. From this theorem it follows that, however such a body may be moving, there is momentarily a line which is at rest. This line is the instantaneous axis of rotation. It always passes through the fixed point, and will as it shifts in time describe two conical surfaces, one in space and the other in the body. Any given continuous motion can then be effected by the rolling of one determinate conical surface fixed in the body upon another fixed in space. As a familiar example take an ordinary spinning-top. Here to the eye there is in general a rotation of the top about its axis of figure, while at the same time the top executes a conical motion about a vertical line through the point of support. In reality, however, at any instant of time the top is subject to *one* rotation about an instantaneous axis, which coincides neither with the axis of figure nor with the vertical line. This instantaneous axis executes a definite conical motion, both in the body and in space. Clerk-Maxwell (see his collected papers) devised a very ingenious and simple optical method for observing the position of the instantaneous axis, and so studying experimentally its motions with reference to the top. It should be mentioned in conclusion that infinitely small rotations are resolved and compounded according to the same laws as velocities and forces, so that we may regard the instantaneous angular velocity of a rotating body as made up of component angular velocities about any three chosen axes. It is thus that the subject is usually treated analytically. Such a treatment, however, is essentially artificial; and for a natural treatment we must go to geometry or to the Calculus of Quaternions (q.v.).

Rotation of Crops. In successful tillage farming it is a fundamental principle that the various crops shall be grown in a well-considered rotation. There are solid reasons for this. The plants, like the animals, of the farm differ much in their habits and in the different sorts of food upon which they subsist. Although all plants tend to exhaust the soil, they do so in widely different degrees; they withdraw from the soil different kinds and quantities of ingredients. Some of the farm crops have long, penetrating roots, which draw nourishment from the deeper layers of the soil; others have short or spreading roots, which ramify near the surface. Certain crops occupy the ground for a much longer period than others; some encourage the growth of weeds or interfere with the proper cleaning of the land; others facilitate the work of eradicating weeds; and finally, the 'crop residues' of the various plants of the farm differ greatly. A glance at the following figures, giving the average weight of the principal ingredients removed (per acre in lbs.) from the soil

by the leading farm crops, will show the importance of growing these crops upon a carefully-considered system of rotation.

	Nitrogen.	Potash.	Lime.	Phosphoric Acid.	Silica.
Wheat (30 bushels)	48	28.8	9.2	21.1	96.9
Barley (40 bushels)	48	35.7	9.2	20.7	68.6
Oats (45 bushels)	55	46.1	11.6	19.4	85.3
Swedes (21 tons)	163	118.5	63.6	32.5	10.0
Turnips (17 tons)	112	148.8	74.0	33.1	7.7
Mangolds (22 tons)	147	390.7	42.9	52.9	17.9
Potatoes (6 tons)	47	76.5	8.4	21.5	2.6
Beans (30 bushels)	99	67.1	29.2	29.1	7.3
Clover hay (2 tons)	102	83.4	90.1	24.9	7.0
Meadow hay (14 tons)	49	50.9	32.1	12.3	56.9

It is thus obvious that by alternating the root, the cereal, and the grass and clover crops the producing power of the soil is more easily maintained, and its exhaustion longer deferred. With the fuller knowledge which is now available both as to the wants of the plants and the means of supplying these wants, it is possible, and in certain cases also practicable, for the farmer to grow with success the same kind of crop on the same land year after year for almost any length of time. A more economical method, however, is to alternate the crops, so that the natural resources of the soil and the repairing influences incident to a judicious rotation may be utilised to full advantage. It was long ago demonstrated in practice that when land lies for a few years under grass and clover it becomes enriched with ash constituents and nitrogen. The grasses and clovers not only increase the quantity of nitrogen in the surface soil by drawing supplies of it from the subsoil and from the atmosphere, but they have also the power of conserving that accumulated nitrogen in a form in which it is easily made available to a crop of grain. Points often insufficiently considered in tillage-farming are the period of growth and the season of the year during which the crop occupies the ground. Judging from the table given above, one would imagine that turnips would require in the form of manure far more nitrogen than is required for wheat. In practice, however, it is well known that exactly the reverse is the case. The difference in the points just mentioned, that is in the period and season of the growth of the two crops, is responsible for this important peculiarity. Nitrification (q.v.), or the formation of nitrates in the soil, is most active during summer and autumn, and the cereal crops thus occupy the ground at the time when the soil is comparatively deficient in nitrates. The root crop on the other hand is in full growth in the autumn, when the supply of nitrates in the soil is at the maximum. Root-crops consumed on the farm are therefore a good preparation for succeeding crops of cereals. The precise form of rotation most suitable for particular farms varies greatly, depending upon various circumstances, and especially the nature of the soil, climate, markets, available supplies of extra manures, amount of live stock kept, &c. That course of cropping is evidently the most desirable which will economically secure, with thorough cleanness of the soil, a high and increasing state of fertility.

Many rotations are based upon the Norfolk or four-course system, which consists of (1) clover or mixed grass seeds; (2) wheat or, in many parts of Scotland, oats; (3) turnips, swedes, mangolds, potatoes, or bare fallow; (4) barley. The details of this system are generally as follows. The clovers or grasses are mown or grazed; when cut they are either used green or are dried for hay; the second crop is carted home for the cattle or horses; near towns it is sold off; or it is consumed on the ground in racks by sheep, which on most highly cultivated farms receive besides a daily allowance of cake or corn. In districts where the town-manure can be obtained a top dressing is applied as soon as the

first crop of grass is cut. On the poor and worse cultivated soils the grass-crop occasionally remains down for two, or even three years, thus extending a four into a five or six years' rotation. The clovers or mixed seeds are ploughed up in autumn, and followed generally in England by wheat, and in Scotland by oats. These crops are now often drilled, to admit of horse and hand hoeing. After harvest the stubble is, if possible, cleaned by the scarifier, grubber, or plough and harrows; or, where the management for several years has been good, any patches of couch-grass or other weeds are best forked out by hand. The land, especially if heavy, or intended for mangolds drilled on the flat, as practised in the drier parts of England, may then be manured and deeply ploughed: the grubber and harrows, in April or May, suffice to prepare for the drilling of mangolds or swedes. Heavy land, intended either for roots or barley, should, in spring, be disturbed as little as possible. In Scotland, and the cooler moist climates of the north and west of England, turnips and potatoes are grown on raised drills or balks, in which the manure lies immediately underneath the plant. Frequent horse and hand hoeings should ensure the thorough cleaning of the crop. Unless in the neighbourhood of towns, where it is greatly more profitable to sell off the whole of the root-crop, part of the swede or mangold crop is taken home for the cattle, and the remainder consumed by sheep in the field. After the fallow or cleaning crop another cereal crop is grown; under the Norfolk system this is generally barley, with which the clovers or seeds are sown out. Where sewage or tank water is available Italian rye-grass is often used, and on land in high condition early large and repeated cuttings are obtained; but rye-grass has the disadvantage of being a worse preparation than clover for the wheat-crop which usually follows. The chief failing of the four-course system consists in the frequent recurrence of clover, which cannot be successfully grown oftener than once in six or eight years. To obviate this difficulty one-half of the clover quarter is now often put under beans, peas, or vetches, thus keeping the grass or clover seeds eight years apart.

The Norfolk four-course system is unsuitable for heavy land, where a large breadth of roots cannot be profitably grown, and where their place, as a cleaning crop, is taken by bare fallow, vetches, or pulse. Bare fallows are, however, much less frequent than formerly, being now confined to the most refractory of clays, or to subjects that are so hopelessly full of weeds as to require for their extirpation several weeks of summer weather, and the repeated use of the steam or horse ploughs, the scarifier, grubber, and harrows. In such circumstances winter vetches are often put in during September or October, are eaten off by sheep and horses in June or July, and the land afterwards cleaned: this practice is extensively pursued on the heavier lands in the midland and southern counties of England. In such localities the following system is approved of: (1) The clover leas are seeded with (2) wheat; then come (3) beans, pulse, or vetches, manured, horse or hand hoed; (4) on good land wheat succeeds; (5) oats or barley often follow, but, to prevent undue exhaustion of plant-food, this system requires considerable outlay in artificial manures, cake, and corn; (6) a fallow, or fallow crop, deeply and thoroughly cultivated, and well manured, comes to restore cleanness and fertility; (7) barley or wheat is drilled, and amongst this the clover-seeds are sown. On the heavier carse-lands in Scotland the following plan of cropping is practised: (1) Clover; (2) oats; (3) beans; (4) wheat; (5) root-crop, usually including a considerable breadth of potatoes; (6) wheat; (7)

barley, with which the clovers or mixed grasses are sown. Under this system it is difficult, with so few cleaning crops, to keep the land clean; roots, besides, are not produced in quantities sufficient properly to supply either cattle or sheep during the winter. To remedy these defects roots may be introduced after the oats, and would be followed either by wheat or barley. This extends the rotation from seven to nine years.

In most well-cultivated districts, whether of heavy or light land, stock-farming is extending, and a more vigorous effort is being made to raise the fertility of the land. Root-crops are accordingly more largely grown; indeed, it is sometimes found profitable to grow two root-crops consecutively; thus, after turnips, swedes, cabbages, or mangolds, well manured from the town or farmyard, and eaten off by sheep, potatoes of superior quality are produced with one ploughing and a dose of portable manure. Specialities of management occur in almost every locality. Near London, and in other southern districts, early potatoes or peas are grown for market, and are immediately followed by turnips. In many parts of England, where the soil and climate are good, rye or vetches sown in autumn are consumed in early summer, and a root-crop then put in.

Good rotations do not necessarily ensure good farming; they are merely means to an end. And as agricultural education and enterprise extend fixed rotations will be less regarded. The market-gardener, who extracts a great deal more from his land than the farmer has hitherto been able to do, does not adhere to any definite system of cropping. If the farm is kept clean and in improving condition there can be no harm in growing whatever crops it is adapted to produce. Cropping clauses are requisite during only the three or four last years of a tenancy. The restrictions found in some agreements, preventing the growth of clover for seed, flax, and even potatoes, are inadmissible. Equally objectionable are clauses against the sale of particular sorts of produce, such as hay or roots. The farmer, if he is fit to be entrusted with the use of the land, ought to be permitted to grow or sell off any crop he pleases, provided an equivalent in manure be brought back. On well-cultivated land, in good condition, it is now the practice of the best farmers to take oats or barley after wheat; indeed, some of the best malting barley in Essex, on the Scottish carse-lands, and elsewhere is now grown after wheat. The frequent growth of cereals, and the heaviest of hay and root crops, even when removed from the farm, may be fairly compensated for by judicious and liberal treatment with town-dung, sewage, or artificial manures. The plant-food disposed of in the more ordinary sales of the farm is economically restored by the use of bones or superphosphate, guano, or nitrate of soda, or by keeping plenty of stock on the farm, and supplying them liberally with cake and corn. See also the articles AGRICULTURE, FALLOW, MANURE, SOILS, and those on the various crops.

Rotatoria. See ROTIFERA.

Rotche, or **LITTLE AUK.** See AUK.

Rothamsted, or **ROTHAMSTEAD PARK**, 4 miles N.W. of St Albans, is noted as the scene of the agricultural experiments of Sir J. Bennet Lawes (1814-1900), and has been developed as a centre of research. See AGRICULTURE.

Rothe, **RICHARD**, one of the greatest speculative theologians of Germany, was born at Posen, 30th January 1799. At the universities of Heidelberg and Berlin he had among his teachers Danb, Hegel, Schleiermacher, and Neander. After a two years' course in the clerical seminary at Wittenberg and a short period of lecturing as *privat-docent* at

Breslau he set out for Rome in December 1823 as chaplain to Bunsen's embassy. In 1828 he accepted a professorship in the Wittenberg seminary, whence in 1839 he migrated to fill a similar position at Heidelberg. In 1849 he obeyed a call to Bonn as professor and university preacher, but in 1854 he returned to Heidelberg as professor of Theology and member of the Oberkirchenrat, and there he died, 20th August 1867. Rothe was one of the noblest types of the theologian that Germany has produced, in his rare combination of simple inward piety with fearless boldness of thought. His conception of the kingdom of God founded by Jesus reminds an English reader of the grand scheme of Hooker in its identification of the religious and moral functions of church and state, in a kind of refined and glorified Erastianism. Indeed the special function of the church will come to an end as soon as the state has become permeated with the religious idea, its purpose being merely that of a temporary instrument in the realisation of this ultimate ideal. The real end of Christianity is to create no hierarchical theocracy, but a spiritualised community with all its social and political functions harmonised with the divine morality. The Catholicism of the middle ages was a grand attempt to realise a visible church, but frustrated its highest end because it denaturalised the true social relations when it gave itself a purpose and a policy antagonistic to the state. The Reformation conception of the *invisible* church was an attempt to avoid the difficulty of the Catholic theory, but it created a purely spiritual community, separated from the ordinary interests of social and national life. This speculative theory is worked out in the first of the three books of Rothe's unfinished work, *Die Anfänge der christlichen Kirche* (1837)—the second and third books are historical. His greatest work is his *Theologische Ethik* (3 vols. 1845-48; 2d ed. completed by Holtzmann from his papers, 5 vols. 1869-71), which supplements the preceding book, being based on the same fundamental identity between religion and morality, the starting-point being the idea of God involved in consciousness, and considered in relation to the world and to man. His *Dogmatik*, posthumously edited by Schenkel (3 vols. 1870-71), completes his ethics. Here he distinguishes sharply between revelation itself and the Bible—its documentary record. The true object of revelation is the knowledge of God; its mode of operation is not magical, but is accompanied by an internal action on the consciousness producing a special receptivity by means of which the external manifestations in history and nature may be understood. It is supernatural in its cause, but natural in its method, although admitting alike of inspiration, of miracle, and of prophecy—no contradictions of nature, but rather inherently constituent elements of a revelation, subserving higher laws of nature unknown to man's limited faculties, but perfectly homogeneous with a divine order. Rothe was an admirable preacher, but with characteristic modesty could hardly be induced to publish his sermons. Schenkel edited three volumes in 1869, but took unwarrantable liberties with the text, in the way of modifying the supernaturalism. A fourth and trustworthy volume was edited by W. H. Hubbe in 1872.

Rothe collected some of his essays under the title *Zur Dogmatik* (1863). After his death, various writings were edited by Wengarten, by Mühlhanser, by Ruppius, by Trümpelmann, and by Nippold, who wrote his *Life* (2 vols. 1873-74). See the critical studies by Achelis (1869), Homig (1898), and Hanstrath (1902-6).

Rothenburg, a picturesque town of Bavaria, surrounded by ancient walls, on the Tauber, 36 miles W. by S. of Nürnberg, preserves its medi-

veal character unaltered. Pop. 9000. It produces annually a procession and historic play in memory of its escape from being sacked by Tilly in the Thirty Years' War, during which the town (then a place of 18,000 inhabitants) was repeatedly taken and retaken.

Rothenstein, WILLIAM, painter, born at Bradford in 1872, studied under Legros at the Slade School, and afterwards in Paris. In 1917 he became professor of Civic Art at Sheffield University, and in 1920 Principal of the College of Art, South Kensington. He is principally known by a number of interesting portraits, in which he shows himself the possessor of great powers of observation, together with the faculty of identifying himself with the personality of the sitter. During the Great War he was appointed one of the official war-artists.

Rotherham, a busy manufacturing town in the West Riding of Yorkshire, on the right bank of the Don, here joined by the Rother, 5 miles ENE. of Sheffield by a railway opened in 1838. Its chief glory is the magnificent cruciform church, perpendicular in style, with crocketed spire and fine west front, and interesting choir stalls and misericords. It is probably somewhat earlier than its reputed founder, Thomas de Rotherham, Archbishop of York (1423-1500), and in 1875 was re-stored by Sir G. G. Scott. The grammar school, founded in 1483, also by the archbishop, at present occupies the building (1875) originally intended for an Independent College. There are also various public buildings, including the infirmary (1870) and the municipal offices (1924); also the Clifton Park, with a fine mansion-house, opened in 1891. Rotherham is a county borough. The manufactures include stoves, grates, chemicals, pottery, glass, railway-carriages, &c. Ebenezer Elliott was a native of the suburb of Mashborough, which is included within the municipal borough, incorporated in 1871. Roche Abbey, a ruin, 8 miles ESE., was a Cistercian foundation (1147); and 8 miles NE. is Conisborough Castle, noticed at DONCASTER. Pop. (1851) 6325; (1881) 34,782; (1921) 68,045.

Rothsay, a favorite Scottish watering-place, the capital of Buteshire, is beautifully situated on the north-east shore of the island of Bute (q.v.), 40 miles by water W. of Glasgow and 19 SSW. of Greenock. It is a great yachting centre, the bay offering safe anchorage in any wind. A harbour was constructed 1822-84, and has been considerably extended since. An esplanade was formed in 1870; and among the chief edifices are the county buildings (1832-67), the academy (1869), and Bute Museum, (1926). In the middle of the town are the ruins of Rothsay Castle, founded about 1098, taken by Haakon of Norway (1263), the death place of Robert III. (1406), reduced to ruin (1685), and repaired in 1871-77 by the Marquis of Bute. Rothsay since 1398 has given the title of duke to the eldest son of the Scottish sovereign. Here the first cotton manufactures in Scotland were started in 1779; but its cotton trade and its boat-building are now extinct. Created a royal burgh in 1400, it returned a member from the Union till 1832. Pop. (1821) 4107; (1881) 8329; (1921) 15,218.

Rothschild, the well-known family of bankers, takes its name from the sign of the house ('Zum Rothen Schilde,' or 'red shield'), in the Jews' quarter of Frankfurt, in which its ancestors lived. The real founder of the family as financial magnates was MEYER AMSCHEL ROTHSCHILD, who was born at Frankfurt in 1743. Although educated for a rabbi, he embarked in the banking business at Hanover, and, having saved a little money, started

for himself as a money-lender and dealer in old coins in the family home at Frankfurt. He won the confidence of the landgrave of Hesse, who entrusted his finances to the Jew's management. The current story, that he successfully hid the fortune of the landgrave from the French invaders in 1806, and was through his patron's gratitude allowed to have the almost free use of it for some years, and so by this means laid the foundation of a large fortune, is extremely doubtful. The beginnings of his fortune were in all probability less romantic: the Rothschild house got a heavy commission for transmitting money from the English government to Wellington in Spain during the eight years of the Peninsular war; they managed the large private fortune of the landgrave; through them the British government made its payments of subsidies to continental princes; they negotiated large loans for Denmark between 1804 and 1812. At his death, on 13th September 1812, Meyer Amshel Rothschild left five sons, all of whom were made barons of the Austrian empire in 1822. ANSELM MEYER, the eldest son (1773-1855), succeeded as head of the firm at Frankfurt. SOLOMON (1774-1855) established a branch at Vienna; NATHAN MEYER (1777-1836), a branch in 1798 at London; CHARLES (1788-1855), a branch at Naples (discontinued about 1861); and JAMES (1792-1868), a branch at Paris. Apart from their very extensive private banking business these houses were very deeply concerned in negotiating many of the large government loans of the 19th century. The cleverest man of the five was Nathan, who really lifted the house into its position as first amongst the banking-houses of the world. He pinned his faith and staked his fortunes on the success of Britain in her great duel with Napoleon; but the story is not true that, having been present himself at the battle of Waterloo, he hastened home to London, where, before the result of the battle became known, he had sold and bought stock that brought him one million sterling clear profit. His son LIONEL (1808-79) distinguished himself by his efforts to effect the civil and political emancipation of the Jews in Great Britain. Lionel's son, NATHAN (1840-1915), succeeded to the baronetcy conferred in 1847 on his uncle Anthony, and was raised to the peerage as Baron Rothschild in 1885. His niece Hannah (1851-90) was in 1878 married to the Earl of Rosebery, and his son LIONEL (b. 1868) succeeded to the peerage. See Reeves, *The Rothschilds* (1887), and I. Balla, *The Romance of the Rothschilds* (1913).

Rotifera, or ROTATORIA, a class of minute aquatic animals, popularly called wheel animals. Most are microscopic (yet with a complex multicellular body), very transparent, and exceedingly active. The majority live in fresh water; some occur in brackish and salt water; two or three genera, e.g. *Seison*, are parasitic. Many may be obtained in damp moss from marshes. The body is bilaterally symmetrical, covered with a chitinous cuticle. Anteriorly there is a soft 'disc' fringed by a complex 'wreath' of cilia, the movements of which (suggestive of a rotating wheel) serve for locomotion and food-wafting. The anterior, sometimes ventral, mouth leads into a gizzard or 'mastax,' with a complicated masticating apparatus (often showing two hammers beating on an anvil); the food-canal ends posteriorly, in most cases dorsally. Rotifers feed on microscopic plants and animals and organic particles. The nervous system consists of a ganglion on the dorsal surface of the beginning of the food-canal, sometimes connected with another on the ventral surface. There are usually eyes and bristle-bearing tactile processes. A pair of excretory tubules open into the end of the food-canal. Posteriorly the body

usually bears a 'foot' containing cement glands, and effecting temporary or permanent attachment. In *Pedalion mirum* the body is prolonged into hollow limb-like expansions, suggestive of the limbs of a simple crustacean. The sexes are separate, but parthenogenesis is habitual. The

Hydatina senta :

a, female dorsal view; b, male ditto.
(*The Rotifera*, Hudson and Gosse.)

males are usually pigmies compared with the females, and they often have no food-canal. They are usually rare, and in some species they have not been found. Fertilised eggs become 'winter' or 'resting' eggs, suited to resist drought and other adverse conditions. The unfertilised ova are often of two sizes, large ones which develop into females, and small ones (produced in other conditions or by females of different constitution) which develop into males. Many rotifers are viviparous.

Many can remain in a state of latent life for a long time without losing the capacity of reviving; in some cases the individual dies, but the ova live on. Common genera are Rotifer, Hydatina, Floscularia, Melicerta, Stephanoceros, Brachionus. The affinities of rotifers are dubious; some authorities link them to Chetopoda, others to simple unsegmented worms. See the fine monograph by Hudson and Gosse, *The Rotifera* (1889), and M. Hartog's account in the *Cambridge Natural History* (1896).

Rotomahana. See NEW ZEALAND.

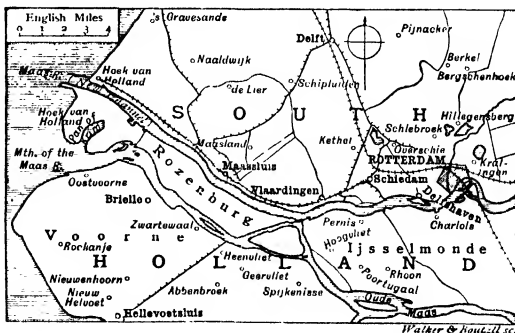

Rotrou, JEAN DE, French tragic poet, was born at Dreux, 21st August 1609, went early to Paris, and became a busy playwright, as well as one of the five poets—the others were Corneille, Colletet, Bois Robert, and L'Étoile—who worked up into dramatic form the ideas of Richelieu. His first pieces, all in the Spanish romantic style, were followed by a busy period of classical influence, culminating in his last years with his three best works, *Le Véritable Saint Genest*, a tragedy of Christian martyrdom under Diocletian; *Don Bertrand*, a comedy; and *Venceslas*, which kept the stage down to the 19th century. Tradition tells that Rotrou led a dissipated life in Paris, and further was inordinately addicted to gambling; more honourable is the authentic history of his death. He held an official post at Dreux, and when he heard that the plague had broken out there, and that the mayor had fled like Montaigne in the same circumstances from Bordeaux, he hastened to the town to preserve order, caught the pestilence, and died a few hours after, 28th June 1650.

As many as thirty-five of his plays are still extant, but many more are lost. A complete edition was edited Violette-Luc (5 vols. 1820-22); six of the plays by de Ronchaud (2 vols. 1882). See *Jarry's Essai* (1868),

two works by Perso (1882), and G. Steffens, *Rotrou-Studien* (i. 1891).

Rottenstone, a soft and earthy stone, consisting chiefly of alumina, with varying amounts of carbonaceous matter and a little silica. It is supposed to be formed by decomposition of shale or argillaceous limestone. It is found in Derbyshire, England, in Wales, and near Albany, in the state of New York. It is brown—either grayish, reddish, or blackish. It is soft and easily scraped to powder, and is well known to housewives, being much used for cleaning and polishing brass and other metals.

Rotterdam, the busiest port of Holland, stands on both sides of the Maas, 19 miles from its mouth, and 16 miles by rail SE. of the Hague and 45 SW. of Amsterdam. Since Holland was separated from Belgium, the trade of Rotterdam has grown at an extraordinarily rapid rate, especially since the middle of the 19th century. New wharves and quays and new docks have been built almost every year since 1847. In 1850 the docks measured scarcely 100 acres. By the end of the century they had more than thrice that area, and at the end of the first quarter of the 20th century the harbour of Rotterdam covered an area of over 625 acres, with 25 miles of wharves all equipped with the most modern appliances. Since 1872 sea-going vessels have ceased to approach Rotterdam by the old channel of Brill (Brielle); they have used instead the New Waterway—i.e. the Maas and the Scheur, the latter of which has been connected with the sea by a canal cut through the Point (Hoek) of Holland. Every effort has been made to render this new waterway available for large ocean-going steamers. The absence of locks makes it possible for heavily laden vessels arriving from the sea to lie moored at the quays or buoys within two hours. At the Boompjes, one of the splendid quays in Rotterdam itself, the river is 30 to 40 feet deep. Taking all the vessels that enter all the ports of Holland from abroad, more than 60 per cent. (estimating by tonnage) enter at Rotterdam, and in 1924 this amounted to over 10,000 vessels of over 15,000,000 tons, an increase from 346,000 tons in 1850, 1,412,000 in 1875, and 5,817,000 in 1901. There is an important trade connection with Germany by way of the river Rhine, and the traffic on the inland canals and

streams is also considerable. In addition, fishing fleets from Vlaardingen and other places enter Rotterdam, and sell herring, cod, &c. The imports, to a large extent from the Dutch colonies, consist chiefly of grain (wheat, rye, oats, maize), coffee, sugar, tobacco, rice, tea, spices, and coal, and the exports of dairy produce, linen, and spirits.

Dutch vessels still do a fair amount of carrying trade. There are flourishing industries, such as iron and other metal works, shipbuilding, distilling, sugar-refining, and the manufacture of tobacco, chemicals, &c.

Rotterdam is intersected by canals, which communicate with the Maas, whilst their banks serve as wharves. On the south side of the river, where the town is expanding rapidly, are the busy iron-works and shipbuilding-yards of the island of Fijenoord, besides some of the largest docks. This island is connected with the other bank by two lofty bridges (one a railway bridge). In the city the more important buildings are the Gothic church of St Lawrence (15th century), with a very large organ, the monumental tombs of the Dutch admirals Witt, Cortenaer, Van Brakel, Van Liefde, and others, and a lofty tower (210 feet high); the Boymans Museum (1847), with a fine collection of paintings by Dutch masters; the old yacht clubhouse, containing an ethnological collection; the new town hall (1909-20), containing a huge complete chromatic carillon; the exchange and similar public buildings. The public institutions include an academy of art and science, schools of music, navigation, and the technical arts, and an excellent zoological garden. Pop. (1830) 72,300; (1858) 104,724; (1890) 203,472; (1905) 379,017; (1922) 531,896. Rotterdam counts as her most illustrious sons Erasmus and the poet Tollens; James, Duke of Monmouth, and Grinling Gibbons, the English wood carver, were also born here. The history of the place is marked by very few notable events, except its capture by Francis of Brederode in 1488, who lost it to the Austrians in the following year, and the occupation by the Spaniards in 1572.

Rotti, an island in the Indian Archipelago, belonging to the Dutch, lies to the south-west of Timor. It is 36 miles in length (655 sq. m.). The surface, though hilly, is nowhere more than 800 feet above the sea, and the fertile soil produces a rich vegetation.

Rottweil, a town of Württemberg, on the Neckar, 68 miles by rail S. by W. of Stuttgart, has manufactures of gunpowder and silk and cotton fabrics, and railway workshops. Near by, on the site of an ancient Roman colony, a number of antiquities, including a valuable piece of mosaic work, have been discovered. Pop. 10,000.

Rotumah, an island in the South Pacific, annexed to the Fiji Islands by Great Britain in 1881, is distant about 300 miles NNW. from the nearest island of that group, of which it is a dependency. Area, 14 sq. m.; pop. 2700, all Christians.

Roturier (according to Littré from *ruptura*, Low Latin for ground broken by the plough), under feudalism, when the feudal theory of knight's-service was recognised as the only principle of gentle tenure, one who continued to hold by the older or allodial tenure, and was accordingly regarded as ignoble. See FEUDALISM, ALLODIUM.

Roubaix, a town in the north of France (dept. Nord), 6 miles by rail NE. of Lille. It rose into importance during the 19th century, and during the Great War was occupied by the Germans. Here cloth for men's clothing, shawls, stuffs for furniture and ladies' dresses, velvet and similar textiles, chiefly of wool, cotton, and silk, are manufactured. Besides these, thread, beer, spirits, machinery, &c. are produced, and there is a very active trade in them. Dyeing is carried on, and there is a cattle market. Pop. (1810) 9000; (1876) 74,946; (1891) 105,191; (1921) 113,265.

Roubillac, LOUIS-FRANÇOIS, sculptor, was born at Lyons in 1695, studied mainly at Paris,

where in 1730 he obtained the second Grand Prix, and shortly thereafter settled in London. In England he spelt his name *Roubiliac*. He visited Rome in 1745. His statue of Handel for Vauxhall Gardens in 1738 first made him popular. His other more famous statues are those of Shakespear (executed for Garrick, and now in the British Museum), of Sir Isaac Newton at Cambridge, and another of Handel in Westminster Abbey. The monuments of the Duke of Argyll and of General Wade in the Abbey are also well known. He contributed greatly to the improvement of British taste in sculpture, though his own work is by no means so perfect as his contemporaries imagined; he has been called 'an exquisite executant but poor designer.' He died in London, 11th January 1762. See the *Life by Le Roy de Sainte Croix* (Paris, 1882); A. Dobson in *Eighteenth Century Vignettes* (1894).

Rouble, the unit of the Russian money system, first cut from silver bars in 1321, and coined in 1655. Russia had nominally a silver standard (though most of the currency was paper) till 1897 when a gold standard was adopted, and gold imperials and half-imperials of 15 and 7½ roubles were coined. Later, gold pieces of 10 and 5 roubles were introduced. The ratio of the gold to the paper rouble was fixed at 1½ to 1. The legal unit of money became the silver rouble, divided into 100 kopecks, of the normal value of 2s. 1½d. During the Great War and especially during the years immediately after, the rouble depreciated enormously, till it was only worth one fifty thousand millionth part of its former value. In 1924 it was re-established approximately at its pre-war rate, and silver and copper coins were issued.

Rouen (Lat. *Rotomagus*), formerly the capital of Normandy, and now the chief town of the department of Seine-Inférieure, and after Lyons perhaps the principal manufacturing city of France, is situated on the right bank of the Seine, 87 miles NW. of Paris by railway. The ramparts have been converted into spacious boulevards, little inferior to those of Paris. The modern streets are well and regularly built, with good stone houses; but a considerable part of old Rouen still remains, consisting of ill-built picturesque streets and squares, with tall, narrow, quaintly carved, wood-framed and gabled houses. The Seine, upwards of 300 yards broad, makes Rouen, although 80 miles from the sea, one of the most important shipping ports of France, with some 30 miles of quays. A stone bridge and a suspension bridge lead to the Faubourg St Sever on the left bank. Rouen possesses several remarkably beautiful Gothic churches—in particular the cathedral (13th century onwards), St Ouen (14th-15th century; perhaps the best specimen of Gothic in existence, larger than the cathedral and containing some good stained glass), and St Maclou (in the florid style of the end of the 15th century). The cathedral, the seat of an archbishop, begun by Philippe Auguste, has a very rich west facade, with two fine west towers—the one on the right (Tour de Beurre) was built (1485-1507) with indulgence money received for permission to eat butter during Lent—but is disfigured by a lofty cast-iron spire (487 feet) erected upon the central tower in 1876 in consequence of an old wooden belfry, which bore the date 1544, having been destroyed by fire in 1822. It contains in its twenty-five highly ornamented chapels numerous monuments of great interest, especially those of Rollo and of his son William Longsword. The cathedral is also noteworthy for its stained glass, the choir, with 96 carved stalls, and the side-portals. The 4th century crypt of the church of St Gervais is reputed to be the oldest Christian building in France. Among other

noteworthy buildings in Rouen are the splendid palais de justice (15th century; the right wing modern), originally built to house the Norman parliament, and now occupied by the law courts; the hôtel-de-ville (13th century, with Renaissance façade); the Grosse Horloge; the Musée des Beaux Arts, containing one of the finest collections of paintings and sculpture in provincial France, and a large library; and the Hôtel de Bourgheulde (15th century, transition period). The principal branches of industry are cotton manufactures of all kinds, including the checked and striped cottons specially designated *rouenneries*. Rouen has also extensive manufactures of hosiery, mixed silk and wool fabrics, blankets, flannels, hats, cordage, linen yarns, chintz, chemicals, paper, &c. Dyeing is carried on, and there are also shipbuilding yards and engineering works. Pop. (1872) 102,470; (1921) 123,712.

History.—Rouen is specially interesting to Englishmen as the capital of the Normen in France, and the first home of the Norman dukes. It was the scene of Rollo's baptism and marriage with Gisela, daughter of Charles the Simple, after that monarch had been constrained to cede Normandy under the treaty of Claire-sur-Epte (912), and there he and his successors lived until Duke William transferred his court to Winchester after the conquest of England (1066). At Rouen William died (1087), and till the time of John it continued the seat of government of the Norman possessions of the English kings. In 1204 it was taken by siege by the French king Philippe Auguste, and annexed along with the main part of the duchy to the French crown. During the wars of Henry V. and Henry VI. of England it was under the power of the English from 1419 to 1449, when it was retaken by the French under Charles VII. It was during this occupation by the English that Joan d'Arc was burned alive (1431) as a witch in the Vieux Marché near the square called in memory of her Place de la Pucelle, in which stands her statue. Rouen was occupied by German troops in 1870-71, and was an important Allied military base during the Great War. It was the birthplace of Corneille (1606), of Fontenelle (1657), of Boileau (1733), of Géricault (1790), of Armand Carrel (1800), and of Flaubert (1821). Clarendon died there.

Rouergue, an old province of southern France, between Langue doc, Auvergne, and Guienne, ruled by counts until 1589, when it passed to the crown. See FRANCE.

Rouge, a powder used to give artificial colour to the cheeks. For commoner purposes vermilion rubbed up with almond-oil is employed, but the safer and better quality is prepared from carmine (the colouring matter of cochineal), either alone or mixed with the safflower colour. These are generally rubbed up with French chalk, and supplied either as powder, or, along with a little oil, in the form of saucers.

Jeweller's rouge is an impalpable preparation of oxide of iron, obtained by gently heating the yellow oxalate of iron or the sulphate till it decomposes, a red powder being left. It is used for polishing silver, and for this purpose should be of the finest quality. Many cheaper varieties are sold under this name.

Rouge Croix, Dragon. See HERALD.

Rouge et Noir (Fr., 'red and black'), TRENTE-ET-UN ('thirty-one'), or TRENTE ET QUARANTE ('thirty and forty'), is a modern game of chance, which is played by the aid of packs of cards on a table covered with green cloth. The table is of a form similar to that shown in the figure. It is divided into four portions, each marked in the centre with a diamond, the diamonds

being alternately red and black; and these quarters are further separated, two and two, by hands which cross the table at its narrowest part. At the end of the table are a series of concentric bands painted of a yellow colour (not represented in the figure). The game is played as follows: one of the *tailleurs* (or dealers, who manage the table, take charge of the bank, and keep an eye on the players) takes up his position at one side of the table, opposite to the *croupier* (another *tailleur*), and unseals, in the presence of the players, six packs of cards, which

Rouge et Noir.

are first counted, then shuffled by several *tailleurs*, and returned to the first *tailleur*, who presents them to one of the players to be cut. This is performed by the insertion of a blank card in any part of the pack, which is then adjusted, and the game proceeds. Each player must stake his money on some one of the four chances, denominated *noir*, *rouge*, *coulour*, and *l'inverse*, which will be afterwards explained. After the stakes have been laid on the table (those for the *noir* being laid on either of the quarters marked with a *black*, and those for the *rouge* on either of the quarters marked with a *red* diamond, those for the 'coulour' on one of the transverse bands, and those for the 'inverse' on one of the yellow circles at the end of the table), the *tailleur* takes a handful of cards from the top of the pack, and deals first for the *noir*, taking one card after another from the top of the handful and placing them on the table side by side, till the number of pips on them amounts to more than thirty, when he stops. He then deals out another row in a similar manner for the *rouge*, till, as before, the number of pips amounts to more than thirty. In reckoning the number of pips, the ace is counted as one, the other plain cards according to the number of pips, and the court-cards ten each. It will thus be seen that the number to which each of the two rows of cards amounts, must be more than thirty and not more than forty. If the value of the first row is nearer thirty-one than that of the second, then the first row, or *noir*, wins; if the contrary is the case, then the second row, or *rouge*, wins. *Coulour* wins if the first card tabled by the *tailleur* is of the winning colour:—for instance, if the first card laid down is a 'spade' or 'club', and if *noir* wins; but if the first card dealt be not of the winning colour, then *inverse* wins, and *coulour* loses. Two (and no more) of the four chances can be winning chances at one time; and the winning players have their stakes increased by an equal sum from the bank, and then withdraw their stake and winnings, while the stakes of the losers are raked by the *tailleurs* to the bank in the centre of the table. When the value of the first, or *noir*-row, is equal to that of the second, or *rouge*-row, it is a *refait*, and the dealer must commence to deal anew from the cards remaining in his hand; when the *refait* occurs the player may either withdraw his stake, or stake on a different chance, with the same or more or less money as he thinks proper. The game of *Rouge et Noir* would be an even one

between the players and the bank were it not for the following regulation: When the points dealt for the noir and the rouge each amount to thirty-one ('un refait de trente-et-un') the half of all the stakes on each of the chances belongs to the bank, and this the players may either pay or have their stakes 'put in prison,' the next deal determining whether they shall belong to the bank or be restored to the player. If a second doublet of thirty-one occurs in the deal immediately succeeding, the stakes which were in prison are diminished by one-half, which goes to the bank, and the other half is 'put into the second prison,' from which it requires two successive winnings of the player to regain them. The chance of 'un refait de trente-et-un' is about once in sixty-four deals. This game superseded *Faro* (q.v.) and *Biribi* in France about 1789, but along with *Roulette* was forbidden by law in 1838. See work cited at *ROULETTE*.

Rouget de Lisle, CLAUDE JOSEPH, author of the *Marseillaise* (q.v.), was born at Lons-le-Saulnier on 10th May 1760. When in 1792 he wrote and composed his celebrated song or hymn he was a captain of engineers stationed at Strasburg. Four months later, as too moderate a republican, he was imprisoned in Paris, but was released after Robespierre's fall. Wounded at Quiberon (1795), he quitted the army, and lived in Paris in narrow circumstances, until Louis-Philippe in 1830 awarded him a small pension. He died at Choisy on 26th June 1836. He published in 1796 a volume of *Essais en Vers et en Prose*; but none of the pieces it contains, nor indeed any of his other books, possess much real merit. The *Marseillaise* was his one inspiration. See books by Poisle-Desgranges (1864), Leconte (1892), and Tiersot (1892, 1915).

Rouher, EUGÈNE, a French statesman, was born at Riom, on November 30, 1814, practised there as an advocate up to 1848, and then was returned to the Constituent Assembly. Towards the end of 1849 he was appointed minister of Justice; and with slight interruptions he was for twenty years a member of the French government. He was chiefly instrumental in negotiating the treaty of commerce between France and England in 1860, and that between France and Italy in 1863, and was thus instrumental in preparing the way for the introduction of the free-trade policy of Napoleon III. In 1863 he was appointed minister of State, and maintained that position until 1870, when he became president of the Senate. A staunch supporter of Napoleon III., and a clever debater, Rouher was, next after the emperor, the chief supporter of the system, domestic and foreign, which came to a disastrous end at Sedan—he was sometimes called the Vice-emperor. After the fall of the empire he fled abroad. But he was returned to the National Assembly for Corsica in 1872, and sat till 1875 as a staunch defender of the ex-emperor. He died at Paris, 3d February 1884.

Roulers (Flem. *Rousselaere*), a town of West Flanders, Belgium, 19 miles by rail SSW. of Bruges, has manufactures of cottons, lace, and chicory, and a trade in linen. Here the French defeated the Austrians on 13th July 1794. During the Great War it was the scene of much fighting. Pop. 26,000.

Roulette (Fr., 'a little wheel'), a game of chance which from the end of the 18th century till the beginning of 1838 reigned supreme over all others in Paris. It continued to be played at German watering-places till 1872, when it ceased in terms of an act passed four years before. *Roulette* then found a home at Monaco. It is played on a table of an oblong form, covered with green cloth, which has in its centre a cavity of a little

more than 2 feet in diameter, in the shape of a punch-bowl. This cavity, which has several copper bands round its sides at equal distances from each other, has its sides fixed, but the bottom is movable round an axis placed in the centre of the cavity, the handle by which motion is communicated being a species of cross or capstan of copper fixed on the upper extremity of the axis. Round the circumference of this movable bottom are 38 holes, painted in black and red alternately, with the first 36 numbers, and a single and double zero; and these 38 symbols are also figured at each end of the table in order that the players may place their stakes on the chance they select. Along the margin of the table and at each end of it are painted six words—*pair, passe, noir, impair, manque, rouge*, which will be afterwards explained. Those who manage the table and keep the bank are called *tailleurs*. The game is played as follows: One of the *tailleurs* puts the movable bottom in motion by turning the cross with his forefinger, and at the same instant throws into the cavity an ivory ball in a direction opposite to the motion of the bottom; the ball makes several revolutions, and at last falls into one of the 38 holes above mentioned, the hole into which it falls determining the gain or loss of the players. A player may stake his money on 1, 2, or any of the 38 numbers (including the zeros), and shows what number or numbers he selects by placing his stake upon them; if he has selected a number or zero corresponding to the one into which the ball falls, he receives from one of the *tailleurs* 36 times his stake—viz. his stake and 35 times more—if he selected only 1 number, 18 times if 2 numbers, 12 times if 3 numbers, &c. The blank rectangles at the bottom of each of the 3 columns of numbers figured on the table are for the reception of the stakes of that player who selects a column (12 numbers) as his chance, and if the ball enters a hole the number of which is found in his column, he is paid 3 times his stake. Those who prefer staking their money on any of the chances marked on the edge of the table, if they win receive double their stake (their stake and as much more), and under the following circumstances: The 'pair' wins when the ball falls into a hole marked by an *even* number; the 'impair,' if the hole is marked *odd*; the 'manque,' if the hole is numbered from 1 to 18 inclusive; the 'passe,' if it is numbered from 19 to 36 inclusive; the 'rouge,' if it is coloured red; and the 'noir,' if it is coloured black. If the ball should fall into either of the holes marked with the single or the double zero, the stakes of those players who venture upon the 6 chances last described are either equally divided between the bank and the players, or as is more commonly the case, they are 'put in prison,' as it is called, and the succeeding trial determines whether they are to be restored to the players or gained by the bank. Should it so happen that at this trial the ball again falls into one of the two holes marked with zeros, then half of the stakes in prison are taken by the bank, and the remainder are 'put into the second prison,' and so on. The *tailleurs* thus have an advantage over the players in the proportion of 19 to 18. The player who bets upon the numbers labours under a similar disadvantage, for although the two zero-points do not affect him in the same way as the player who stakes upon one of the other 6 chances, still (supposing him to bet upon a single number) as the chances are 37 to 1 against him, he ought to receive 37 times his stake (besides the stake) when he does win, whereas he only receives 35 times that amount, a manifest advantage in favour of the bank in the proportion of 37 to 35.

Roumania. See RUMANIA.

Roumanille. JOSEPH (1818-91), born at St Remy (Bouches-du-Rhône), was successively teacher, printer's reader, and bookseller, and obtained the fame of being the greatest of modern Provençal poets, next after Mistral. He was one of the founders of the association of the *Félibres* (see **PROVENÇAL LANGUAGE AND LITERATURE**).

Roumelia (Turk. *Rum İli*, 'land of the Romans')—the inhabitants of the Eastern Roman empire, or Byzantine (Greeks, being known to the Turks as 'Romans'), a name which once applied generally to the whole of ancient Thrace and part of Macedonia. The province aptly enough called Eastern Roumelia is now incorporated with Bulgaria (q.v.). In central Asia *Rum* or *Rumi* means the peoples of western Asia; but the Sultan of Turkey was *Rum-Padishah*. Among the Turks *Rum* means now usually the Greek nation and the Greek Church.

Round, in Music, a short vocal composition, similar to the catch, and like it, peculiar to England. It is in the form of an infinite Canon (q.v.) at the unison or octave, each part in succession taking up the subject at a regular rhythmic interval, and returning from the conclusion to the commencement, and so on, *ad libitum*, till an agreed-on pause. These rounds or *roundelays* are usually termed 'merry,' and many of them deserved the name something too well. The most ancient specimen now extant of vocal composition in polyphony is the famous *Rota* or Round, 'Sumer is iucmen in,' of the 13th century.

Round Churches (see **ROMANESQUE ARCHITECTURE**) are represented in England by the Temple Church (see **TEMPLES**); St Sepulchre's at Northampton (q.v.); the Church of the Holy Sepulchre at Cambridge (q.v.); and the Church of Little Maplestead in Essex.

Roundheads, the nickname given by the adherents of Charles I. during the Great Rebellion to the Puritans, or friends of the parliament, who, with Prynne, denounced the 'unloveliness of love-locks,' and were understood to distinguish themselves by having their hair cut close, while the Cavaliers wore theirs in long ringlets.

Round-robin, a word with various homely meanings—e.g. pancake, disrespectfully used in the 16th century of the consecrated host; specifically a protest or remonstrance signed by a number of persons in a circular form, so that no one shall be obliged to head the list, as by sailors threatening mutiny. In literary history a memorable round-robin is that sent by Burke, Gibbon, Reynolds, and others to Johnson, requesting him to amend the epitaph for Goldsmith's monument, and suggesting that it should be written in English, not Latin. Johnson took it kindly, but told Sir Joshua, who carried it to him, that he would 'never consent to disgrace the walls of Westminster Abbey with an English inscription.'

Round Table. See **ARTHUR**, and **ROMANCES**.

Round Towers. Tall narrow circular towers tapering gradually from the base to the summit, found abundantly in Ireland, and occasionally in Scotland, are among the earliest and most remarkable relics of the ecclesiastical architecture of the

British Islands. They have long been the subject of conjecture and speculation, but there is now no doubt that they are the work of Christian architects, and built for religious purposes. They seem to have been in all cases attached to the immediate neighbourhood of a church or monastery, and, like other early church-towers, they were

Round Tower, Ardmore
(From a Photograph by J. Lawrence, Dublin.)

capable of being used as strongholds, into which, in times of danger, the ecclesiastics could retreat with their valuables. In the Irish records, for two centuries after 950 A.D., they are invariably called *Cloutheach* or bell-towers, and are often mentioned as special objects of attack by the Northmen. About 108 towers of this description are yet to be seen in Ireland, twenty of which are entire or nearly so; and Scotland possesses three similar towers—at Brechin, Abernethy, and Egilsay in Orkney. They are usually capped by a conical roof, and divided into stories, sometimes by yet existing floors of masonry, though oftener the floors have been of wood. Ladders were the means of communication from story to story. There is generally a small window on each story, and four windows immediately below the conical roof. The door is in nearly all cases a considerable height from the ground. The figure represents the tower at Ardmore, County Waterford, which is one of the most remarkable of those remaining in Ireland. Rising from a double plinth course at the bottom to a total height of 95 feet, it is divided into three stages by external bands at the offsets, corresponding to the levels of three floors within, the fourth being also marked by a slight offset. Most of these towers, however, have only a slight batter externally from top to bottom. Some, like that of Devenish, are carefully and strongly built of stones cut to the round, and laid in courses, with little cement; others, such as those at Cashel and Monasterboice, have the stones merely hammer-dressed and irregularly coursed; others, again, like those of Lusk and Clondalkin, are constructed of gathered stones untouched by hammer or chisel, roughly coursed, and jointed with coarse gravelly mortar; while in others, as at Kells and Drumlane, part of the tower is of ashlar, and the rest of rubble masonry. The average height of these towers is from 100 to 120 feet, the average circumference at the base about 50 feet, and the average thickness of the wall at the base from 3 feet 6 inches to

4 feet; the average internal diameter at the level of the doorway is from 7 to 9 feet, and the average height of the doorway above the ground-level about 13 feet. These doorways always face the entrance of the church to which the towers belonged. All the apertures of the towers have inclined instead of perpendicular jambs, which is also an architectural characteristic of the churches of the same period, and the sculptured ornamentation of the apertures or walls of the towers is in the same style as that of the churches. These remarkable structures are assigned to a period ranging from the 9th to the 12th century. The source whence this form of tower was derived, and the cause why it was so long persisted in by the Irish architects, are points, however, on which there is not the same unanimity of opinion. Two round towers, similar to the Irish type, are to be seen in the yet extant plan of the monastery of St Gall in Switzerland, of the first half of the 9th century; and, in the Latin description attached to the plan, they are said to be *ad universa superspicienda*. The church and towers as rebuilt at that date are no longer in existence; but a passage in the life of St Tenganan of Brittany shows that this type of round tower detached from the church was in use on the Continent in the 7th century, 'wherein to deposit the silver plate and treasure of the church and protect them from the sacrilegious hands of the barbarians should they wish to pillage the church.' Lord Dunsraven traced the type from Ireland through France to Ravenna, where there are still six remaining out of eleven recorded examples. Suffolk and Norfolk contain more round-towered churches than does all the rest of England, probably because the flint there prevalent is worked into this form more readily than any other stone. A modern round tower is 'O'Connell's monument in Glasnevin Cemetery, which is 160 feet in height.

Roundway Down, a hill about 1½ mile N. of Devizes, in Wiltshire, the scene of Waller's defeat by the royalists under Lord Wilmot in July 1643. Waller was besieging Devizes when Wilmot came up to relieve the town, whereupon he turned at once to meet him, but was quickly crushed between Wilmot on the one side and a sally of the garrison on the other. Waller escaped, but only with the loss of his artillery and most of his men.

Round Worms (*Nematode*), a class of worms in which the body is elongated and more or less cylindrical. Most are parasitic, such as *Ascaris lumbricoides* and *Oxyuris vermicularis*, common in man, and numerous species of *Tylenchus*, which infest plants. Many genera, however, live in water or in moist earth, and many of the parasites are free-living during part of their life. They are called round worms, in contrast to the flat worms or Plathelminthes, such as tapeworms and flukes. For classification, see **THREAD-WORMS**.

Roup is one of the most serious diseases which the poultry or pheasant keeper has to fight, because in it there is generally an affection other than the mere cold which develops and makes it apparent. It is usually found that the system is scrofulous, which is the milder form; but sometimes it takes a diphtheric development, and this is the most severe and deadly disease known to poultry-keepers. Whether scrofulous or diphtheric, it is highly contagious, and very seldom is any bird in a yard attacked without nearly all the others being also affected. The difference between ordinary cold and roup is very easy to determine, though the symptoms are in some respects the same. But when it is merely cold the running at the eyes and nostrils is not at all offensive, whereas it is strongly so in the case of roup from scrofula, the breath being most repulsive. This fact, as well as the swelling

of the face, may be taken at once to determine when it is roup. The cause may generally be sought for in bad feeding, housing, or ventilation, which have charged the blood with scrofulous matter, and the outward symptoms are induced by cold. When first noticed the birds affected should at once be isolated, in order to prevent the spreading of the disease, which will speedily follow if all are kept together. The treatment must be dual, namely to cure the cold and to remove the scrofula from the blood. For the former any of the roup pills sold can be used, or it may be removed by homoeopathic tincture of aconite given three or four times a day, the birds being kept in a warm and draughtless place. The scrofula is not so easily eradicated, and will require patience. Ordinary-sized pills made of powdered charcoal 10 parts, dried sulphate of iron 1 part, and capsicum 1 part, made up with butter, and given twice a day, form an excellent medicine, when the roup proper in its more active state is removed. To do this, however, it is desirable to clear the mouth, nostrils, and eyes from the mucus which accumulates there and which will suffocate the bird if not removed. In milder cases it is enough to wash the parts with vinegar and water, but in more severe cases it is better to use solution of chlorinated soda, as it is much more effective. Should the nostrils be very full of mucus, a small bent syringe should be filled with the solution, which must be inserted into the slit in the bird's mouth, through which the liquid is forced, and will effectually clear the passages. It is most essential in returning the birds to the house again to see that they are entirely recovered. When diphtheric roup is present the matter assumes a more serious aspect, because of the danger not only to other birds, but also to human beings, who have been known to contract this fell disease from birds. For that reason the greatest care must be taken, and, except in the case of very valuable fowls, it is much safer to kill those affected and bury them in quicklime. The outward symptoms in diphtheric roup are not nearly so apparent at first sight, because less prominent; still, the bird is noticed to be dull and lethargic. Unless checked the disease runs its course in a few hours, and the bird dies. Very often it is not known that diphtheric roup is present until several deaths have taken place. Its presence is easily distinguished by the skin-like substance formed over the throat. Treatment is doubtful, and Professor Whalley recommends that it should take the heroic form of dabbing the throat with carbolic acid, which will kill or cure.

Roup, in Scotland. See **AUCTION**.

Rous, FRANCIS, was born at Halton, Cornwall, in 1579, and educated in Oxford at Broadgates Hall, now Pembroke College. He was a member of the Long Parliament, sat in the Westminster Assembly of Divines, and in 1643 was made provost of Eton. He died at Acton, 7th January 1659, his writings having been collected two years before. Wood is abusive even beyond his wont to 'the old illiterate Jew of Eaton' and his 'enthusiastic canting.' His metrical version of the Psalms was recommended by the House of Commons to the Westminster Assembly, and is still substantially the Presbyterian Psalter. It is easy to abuse his version—Sir Walter Scott's verdict was that, though homely, it is 'plain, forcible, and intelligible, and very often possesses a rude sort of majesty, which perhaps would be ill exchanged for mere elegance.'

Rousseau, JEAN BAPTISTE, a great lyric poet of France, was born at Paris, 8th April 1671, the son of a shoemaker who gave him a sound education. At an early age he became acquainted with Boileau, and began to produce pieces for the theatre,

with but little success. Among his earliest patrons were Breteuil and Tallard, and the latter carried him in his suite to London. His turn for satire soon brought him troubles as well as reputation, and some lampoons upon the literary frequenters of the Café Laurent, chief of whom were La Motte and Saurin, brought down upon his head a quarrel that distressed the remainder of his life. Defeated by La Motte in 1710 in his canvass for T. Corneille's chair at the French Academy, he was soon after taken by everybody for the author of a fresh series of scurrilous and indecent couplets. He charged Saurin with writing them and attempting to foist the paternity upon him, and raised an action against him. Failing to make good the charge, he found himself in 1712 condemned in absence to perpetual banishment *par contumace*. Henceforth he lived abroad under the patronage of the Comte de Luc, French ambassador to Switzerland, and afterwards of Prince Eugene and the Duc d'Arenberg. At Brussels he made the acquaintance of Voltaire, but from a friend the latter soon became a bitter enemy. Rousseau visited England, and there published in 1723 a new edition of his works. He was never successful in getting his banishment annulled, although once at least he visited Paris incognito. He died at Brussels, March 17, 1741. Rousseau was not a great, only a supremely clever poet. His sacred odes and *cantates* are splendidly elaborate, frigid, and artificial; his epigrams, on the other hand, are bright, vigorous, sharp, with stinging satire, and unerring in their aim.

Editions are by Amar (1820) and A. de Latour (1869). See his *Œuvres Lyriques*, by Manuel (1852), *Contes inédits*, by Luzarche (1881), and *Œuvres Posthumes*, with Essay by Auger.

Rousseau, JEAN JACQUES, was born on June 28, 1712, in Geneva, where his family had been settled since 1550, when Didier Rousseau, a French Protestant, sought shelter from persecution. His mother died immediately after his birth, and he was left to the companionship of his father, Isaac Rousseau, a watchmaker and dancing-master, a man selfish and sentimental, passionate, dissipated, and frivolous. In 1722 his father having involved himself in a brawl fled the city to escape imprisonment, and left him to the charitable care of his relations. When he was thirteen his uncle apprenticed him to a notary, who soon found him utterly incompetent, and sent him back as a fool; and thereafter he was apprenticed to an engraver, whose cruelty during the three years he lived with him, he says, made him stupid by tyranny, cunning from fear, and wretched by ill-treatment. One evening, having rambled beyond the city walls till the gates were closed, he was too terrified to face his master, and resolved never to return, but to seek elsewhere his fortune. Now, in 1728, began his adventurous and vagrant career, for the details of which his *Confessions* form our chief authority, in which with picturesqueness and charming vivacity, with marvellous frankness, if not with scrupulous accuracy, he tells the story of his life. As he wandered on he was entertained by a priest of Savoy, eager for proselytes from heresy, and Jean Jacques, pretending to be eager to espouse the Catholic faith, was sent off to Madame de Warens at Annecy, who should look after the Calvinistic vagrant. By her he was hospitably received and then transmitted to a hospice in Turin filled with some fellow-catechumens; and soon initiated into the faith and duly baptised, he was discharged with a few francs in his pocket. He in vain sought work as an engraver, till a shopkeeper's wife gave him employment, and to her he acted in the double capacity of servant and lover, till on her husband's return he was kicked

out of doors. He next became footman to a Comtesse de Vercellis, and on her death not long after he took service again as lackey to Comte de Gouvon, and as nondescript secretary to the abbé, his master's son, till he became intolerable both to his masters and his fellow-servants, and was summarily dismissed.

Now in 1731 he travelled back to Madame de Warens, who welcomed him and installed him as permanent inmate of her house. Madame de Warens or, as her name was otherwise written and pronounced, Vorrans or Vuarans, lived apart from her husband a very independent life, having a pension, which late investigation suggests may have been earned by acting as a political spy. She was twenty-eight years old, pretty and piquant, kindly in disposition, not rigid in morals, but rich in sentiment. She was clever and flighty, dabbling in chemistry and alchemy, dabbling also in commercial speculations which made her the dupe of adventurers, and indulging in religious speculations which combined Deism in creed with Roman Catholicism in worship. To her Jean Jacques, now nineteen years old, became pupil and friend, factotum, and ultimately lover, through nearly nine years. This period was diversified by adventurous interruptions: he at one time set himself up in Lausanne as a teacher of music though hardly able to play a tune, and as a composer though not able to write a score; became secretary to an archimandrite of the Greek Church, collecting subscriptions to recover the Holy Sepulchre; and then went to Paris as servant to an officer. Thereafter he returned to live with Madame de Warens at Chambéry, and from 1736 at Charmettes, in which lovely retreat his happiest and iddest years were spent, in desultory reading with his *manan*, in music, indolence and sentiment. This attachment and companionship ceased ingloriously at last when on returning from recruiting his health at Montpellier he found himself supplanted in the heart of Madame de Warens by one Vintzenried, whom he describes as a journeyman wig-maker, ugly and a fool, who as a lover was tyrannising over his feeble mistress, mismanaging her affairs and dissipating her money. In disgust in 1740 Jean Jacques quitted his beloved Charmettes, the idyllic memories of which lived in his heart, as by his picturesque description they live immortal in literature. He became now tutor in Lyons to the sons of M. de Mably, the brother of the famous Condillac and of the once well-known Abbé de Mably, where he taught with lamentable incapacity.

In 1741 he set off to seek his fortune in Paris, with a little money, some letters of introduction to Parisian notables, and a system of musical notation by which he expected to make his reputation. He had to live in a dirty, shabby inn, and to earn a meagre livelihood by copying music, while his musical system was pronounced by the Academy of Sciences 'neither useful nor original.' After a sojourn of eighteen months at Venice, where he acted as cheap secretary to the embassy till he quarrelled with the ambassador, he returned to his inn, his copying, and a secretaryship with M. de Francueil. Meanwhile he had formed a companionship with a girl he found acting as drudge at the inn, called Thérèse le Vasseur, utterly illiterate, densely stupid, plain-featured, mean and vulgar, although he imagined her possessed of every grace in body, mind, and soul. By her he had five children, each in turn deserted and consigned by him to the hospital for foundlings. He had gained acquaintance with men of letters, with d'Alembert and Diderot, as needy as himself; and when they were producing the famous encyclopædia he wrote articles, of which the most

notable were those on music and political economy. His first distinguished appearance in literature was in 1749 by a *Discourse on Arts and Sciences*, written successfully for a prize offered by the Academy of Dijon on the problem whether science and the arts have corrupted or purified morals. Here with bold paradox he denounces fiercely and eloquently letters, arts, sciences, and all culture as alike proofs of and causes of corruption. The audacious independence of his thought, the freshness of his brilliant style, made him at once celebrated in literary and welcome to fashionable circles of society. In 1753 he next made himself distinguished as a composer by his opera the *Dévon du Village*, full of novel and sparkling airs (one of which, slightly modified, is the well-known hymn-tune called *Rousseau's Dream*), which was first played with success before the court at Fontainebleau, and when performed in Paris achieved for him a popularity which was not sustained by subsequent efforts. It was in the same year that there appeared his *Discourse on the Origin of Inequality*, which, though unsuccessful in winning the prize from the Academy at Dijon, was successful in establishing his position as a writer in France. In this discourse he argues that all civilisation is a state of social degradation, that all science and literature, all social institutions and refinements are forms of degeneration from the primeval savage life, which, with all its ignorance and brutishness, he audaciously pronounces the state of human simplicity and perfection. All property is asserted to be derived from confiscation, all wealth is a crime, all government is tyranny, all social laws are unjust.

His brilliant denunciation of society made him the more attractive in society; but hating alike the company of wits and of courtiers, and despising fashionable conventions, he lived poorly, dressed meanly, and acted churlishly to show his independence, with that morose self-consciousness, blended with vanity, which was becoming with him a disease. Gladly he accepted from Madame d'Épinay the offer of a retired cottage, the Hermitage, on the skirts of the forest of Montmorency, near her own château Chevrete. There he retired with Thérèse, her obnoxious mother, and his meagre chattels. Still earning his living by copying music, which produced about £60 a year, he employed his days amidst the woods of Montmorency with conceiving and writing his romance, *The New Héloïse*, inspired in the composition of its rapturous passages by a passion he had formed for Madame d'Houdetot, sister-in-law of Madame d'Épinay. His suspicious temper fostered misunderstandings with his patroness, and bitter quarrels with her friend Baron Grimm, and with his own warm friend Diderot; and he quitted the beloved Hermitage with reluctance for a cottage at Montlouis not far off, where he found kind friends in the Duke and Duchess of Luxembourg. In 1760 the *New Héloïse* was published, and was instantly received with applause, and Rousseau became the idol of the sentimental artificial society of Paris. His work was followed in 1762 by the treatise on the *Social Contract*, published in Amsterdam in order to escape French censorship; and there two months later also appeared *Émile*. By the first work the recluse rose to the first rank as a writer of the romance of sentiment; by the second as a political socialist; by the third as an educationist.

But the views in *Émile* on kings and government made him obnoxious to the state, and the parliament condemned the author to be arrested and his book to be burned; while its deistic teaching in the Savoyard vicar's confession made him hateful to the church, and called forth a denunciatory pastoral from the Archbishop of Paris. Rousseau in terror

fled from France, and found shelter at Motiers, an obscure village in Nenchâtel, where he was safe under the tolerant rule of Frederick the Great, and the friendship of the Earl Marischal, George Keith, the governor of the province. Although he lived unobtrusively in botanising rambles, in making lace, and in writing his aggressive *Letters from the Mountain*, and his powerful reply to the Archbishop of Paris, religious rancour followed him to the remote and peaceful Val de Travers. The ministers stirred up the villagers against the heretic, and to escape their open hostility he took flight in 1764. A residence of delicious quietude in St Pierre on Lake Bienné was ended by threat of prosecution from the government of Berne; and he accepted the offer of a home in England, given through David Hume. Under the charge of the good-natured historian, the irritated and sensitive fugitive came to England in January 1766. During about eighteen months he lived at Wootton in Staffordshire, solitary and quiet: here he busied himself with botany and his *Botanical Dictionary*, and especially in composing his *Confessions*, in which he determined to write his memoirs, to expose his enemies, to reveal himself—in spite of every fault, which he resolved to own—as one of the very 'best of men.' His suspiciousness, his morbid distrust and fears, had increased with his trials and his years. He had quarrelled with almost every friend, imagining the worst meaning in the best of motives; he believed that his truest friends, like Hume, acted with the most sinister designs, that the English government sought his life, and that he was everywhere dogged by spies. Suddenly he quitted Wootton, and, crossing the Channel, got a shelter from the *dortuaire* Marquis de Mirabeau, and then from the Prince de Conti at Trye; and there he lived, under the name of 'M. Renou,' till he fancied that he was insulted by the domestics and that he was suspected of poisoning a servant. After various shifty changes he lived at Monquin, a retired, quiet spot, where he composed those later parts of his *Confessions*, in which each incident is coloured by his gathering delusions as to the motives of every one with whom he came in contact. In 1770 he returned to Paris, and remained unmolested, following his old life as copyist at ten sous a page, in a fifth story in the Rue Plâtrière, maintaining a surly independence, distrusting his friends, rebuffing admirers, insulting his customers. During these years, in different moods of mind and changing conditions of his broken health, he wrote the wild, half-mad dialogues, *Rousseau juge de Jean Jacques*, in which he vindicates his character in a strain which casts doubt on his sanity, and his *Rêveries du Promeneur Solitaire*, which, in singular contrast, are calm in their tone, idyllic in their beauty, and perfect in their style. Still the delusions increased, and his mental misery deepened till he even craved for shelter in a hospital; everywhere he felt watched by spies, hated by the very children in the streets. In 1778 he accepted the last of these many offers of shelter, and retired to a cottage given him by M. de Girardin on his estate at Ermenonville, 20 miles from Paris. There he suffered from the misconduct of Thérèse, and from inveterate delusions, till, with a suddenness which has given much ground for suspicion of suicide, Jean Jacques Rousseau died on July 2, 1778. His body now rests in the Panthéon.

If the character of Rousseau can be learned from the judgment of his friends and foes, it can be also discovered from his own writings, which tell the story of his life—his *Confessions*, his *Letters*, his *Reveries*. We may receive his own version of many of his own acts with doubt, and his interpretation of the acts of others with reserve, while

under Busby, and studied law in the Middle Temple; but early inheriting a small competency by the death of his father, he devoted himself to literature. Between 1700 and 1714 he produced eight plays, of which three were long popular, and deservedly: *Tamerlane* (1702), *The Fair Penitent* (1703), and *Jane Shore* (1714). The character of Lothario in *The Fair Penitent* was the prototype of Lovelace in Richardson's *Clarissa Harlowe*, and indeed the name is still the proverbial synonym for a fashionable rake. Rowe translated Lucan's *Pharsalia*, and his work, says Dr Johnson, 'deserves more notice than it obtains, and as it is more read will be more esteemed.' His edition of Shakespeare (7 vols. 1709-10) at least contributed to the popularity of his author. Rowe's comedy, *The Biter* (1705), lived only to be damned as it deserved. Rowe, we are told, had no heart, yet his vivacity and engaging manners procured him many friends and several lucrative offices. The Duke of Queensberry made him his Under-secretary of State. In 1715 he succeeded Tate as poet laureate; and the same year he was appointed one of the surveyors of customs to the port of London; the Prince of Wales made him Clerk of his Council, and the Lord Chancellor Parker secretary of Presentations in Chancery. He died December 6, 1718, and was buried in Westminster Abbey. See Hart's edition of *The Fair Penitent* and *Jane Shore* (1907).

Rowing. The oarsman sits with his face to the stern of the boat, his feet planted flush against his 'stretcher' or footboard, and the handle of his oar in his hands, the loom of the oar resting in the rowlock, the 'button' being inside the thowl-pin. He should sit upright, with a rigid back, and do his work mainly with his back and legs, using his arms as couplings between his body and the oar handle, and only bending them towards the finish of his stroke. To row a stroke, swing the body forward from the hips straight towards the toes; extend the arms rigidly, brace the shoulders, and keep the head up. The hands should be holding the oar-handle about $3\frac{1}{2}$ inches apart. The grasp should be with fingers and not fist—i.e. the lower knuckles of the hand should be very slightly bent, almost straight, the hold being retained by the upper joints of the fingers and by the thumb. This mode of holding the oar gives freer play to the wrist-joints for the 'feather,' of which more anon. The body being thus extended, and the legs opened at the knees to allow the body free swing forward, and the hands thus grasping the oar-handle, then the stroke is begun by raising the hands enough to allow the blade of the oar to sink into the water square. (It is most important that the blade should be square to the plane of the surface of the water; otherwise, as soon as the stroke commences, the blade fails to preserve its own plane, and sinks too deep, or springs out of water, according as the face of it is inclined at an obtuse or acute angle to the water.) When the oar has been thus lowered into the water, by raising the hands over the stretcher, the stroke should commence sharply, by bracing the muscles of back, loins, shoulders, and legs, and throwing the body backwards, swinging from the hips, the feet firmly pressing against the stretcher, the arms rigid; so that the weight of the body is eased as much as possible off the seat, and is transferred to the oar-handle and the stretcher. When the body has reached the perpendicular in the swing back, the arms should begin to come in. The action of bringing them in should be from the shoulders, the elbow-joints gradually bending, but the forearm remaining as near as possible parallel

to the water. The 'biceps' should not be exerted, else the forearms bend upwards, the hands rise, and the blade buries. The body should not 'wait' for the arms and hands to overtake it: it should be still swinging back till the hands overtake it.

When the hands reach the breast-bone they should be sharply dropped about two inches: this raises the oar out of the water. After this drop of hands they should be turned sharply from the wrists till the knuckles touch the body. This turn produces the 'feather.' If the turn is made too soon, before the hands have reached the chest, the action is faulty, and produces what is called 'feather under water,' by turning the oar edgewise in the water instead of after the oar has left the water. So soon as the drop and turn of wrists has ended and 'feather' has been performed, the 'recovery' should commence. The body should instantly, and without 'hang' or delay, commence to swing forward again like a pendulum. The hands should at the same instant be shot out and the arms extended, reaching their extension by the time that the body has once more attained the perpendicular in its forward swing. The swing should continue forward till full reach has been attained for a new stroke; then once more the hands should be raised, the oar lowered into the water, and a new stroke rowed. In rowing behind another oarsman the eyes should catch the back in front of the oarsman, who should take time and swing from it—keeping 'eyes in the boat.' The oarsman at first finds it difficult to 'govern' his blade—i.e. to keep it in the right plane and at the correct elevation or depression, according to whether he is rowing the stroke or is 'recovering.' In time his wrists become more apt, and time their action to the ever-varying positions of the body. The more he attends to a correct grasp of his oar-handle the easier will be the play of his wrists, and the greater facility will he find in regulating the plane of his blade. It has been said before that the blade should be 'square' to the water throughout the stroke. So it appears to the oarsman; but in well-constructed boats the 'thowl' is slightly inclined in the direction in which the oarsman is looking; this inclination gives the oar-blade a correspondingly slight inclination forward, making it describe a trifle less than a rectangle with the water, and so obviates any tendency to row 'deep.' It will suffice if the beginner thinks of keeping his blade 'square'; and the small deviation from the square, reducing the angle that is effected by the slope of the thowl for his benefit, will then be produced naturally by the mechanism of his work. If this inclination of the thowl is made too great the oar has a tendency to fly out of the water.

To stop the way of a boat she should be 'held.' This is done by laying the blade flat, and thus slightly sinking the edge which lies towards the direction in which the boat is travelling. This causes the blade to bury at an acute angle to the plane of the water. This checks the way until it is reduced enough to allow the oarsman to turn the blade square, reverse way, and to 'back' water. If he tries to back water with any pace on, before he has first 'held' the boat, the resistance to his blade not only risks fracture, but is likely to be beyond his strength, to lay him flat on his back, and to make him 'catch a crab.' In backing water the process of the stroke, described above, should be reversed, so far as circumstances will allow—i.e. the oarsman has no stretcher to press against, and is 'pushing' with his weight instead of 'pulling.' In most 'tub' boats, and in all racing boats, straps are laid across the stretcher, to hold the feet at the instep, and so to facilitate recovery. The strap should only be used as an adjunct to recovery, not as the sole

means: the loins should play their part in swinging the body forwards; and the arms, by being rapidly shot out, should aid the action of the loins. If a tyro is found to rely too much on his strap, a mentor may with advantage remove the strap until proper use of the loins has been effected.

Sculling.—In sculling each hand holds one scull, instead of there being two hands on one oar as in 'rowing.' The principles of action of body, legs, and arms are the same as in rowing, except that the body, when sculling, may with advantage be swung farther back at each stroke than in rowing. The grip of a scull should be on the same principle, as regards holding in fingers and not in fist. The thumb should not chafe under the handle, but cap the butt of the scull with the top joint. In rowing this would be wrong; but in sculling it is found to secure the better hold, and to give freer play to the wrists for feathering. It is important that both hands should work together, both blades entering and quitting the water together, and both wrists feathering simultaneously. If one hand is later than the other the course of the boat is distorted at each stroke.

BOAT-RACING.—Virgil, in *Æneid*, iv., describes a boat-race between four Trojan galleys; and the word 'regatta' is of Italian origin. But modern boat-racing may be said to be an Anglo-Saxon sport. Since 1895 America, Canada, Belgium, Germany, and Australia have invaded Henley regatta with considerable success, and Belgium and Australia have displayed examples of cultivated styles which many British clubs might wisely study as regards elbow finish and clean feather. Twice this century have Ghent eights won the Grand Challenge; and Sydney, Australia, scored in their only essay, 1912 (though Leander beat them at the Olympic Stockholm regatta later on). The body swing of the best British eights is longer and more effective than that of the visitors aforesaid; but in finish of the stroke, and thence in accuracy in quitting the water, those same visitors can teach us much. British 'finish' of the stroke has become slovenly since 1900. Canadians put up many a good light, but have not yet had the luck to win. American Cornell and Pennsylvania University eights have reached final heats in the Grand, but failed to win outright.

Eton and Westminster schools practised boat-racing in the early part of the 19th century; thence the pastime seems to have spread to the universities. One of the earliest races was between Westminster boys and the 'Temple' crew, in six oars, the boys winning. As early as 1815 college 'bumping' races in eight oars had begun at Oxford. In those days only three or four colleges manned eights. Cambridge adopted a similar sport at much the same date, or a year or so later. In 1829 the first Oxford and Cambridge match was rowed—Hambleden Lock to Henley Bridge. The next was in 1836, Westminster to Putney; after that at intervals till 1856, since which date these matches have been annual. Each university has won about the same number of matches. Also, five times have the U.B.C.'s been drawn together in the same heat for the 'Grand Challenge' at Henley, of which Oxford won 3 and Cambridge 2 encounters; and once Oxford beat Cambridge in an encounter for the 'Gold Cup' at the now extinct Thames regatta of the 'forties.' 'Outriggers' were first used by the two university crews in 1846. Sliding seats were first used by them in 1873. 'Keelless' eights were first used by them in 1857. In 1845 the Putney to Mortlake course was first adopted for these matches. Outriggers are a contrivance for artificially extending the gunwales of a boat, so as to give the required leverage for the oar in the rowlock, while the rest of the hull is narrowed to

offer less resistance to the water. The earliest application of the principle was with wooden outriggers on the Tyne before 1836. Iron outriggers were first used by H. Clasper for a Tyne firm in a Thames regatta in 1844.

Professional Racing.—The earliest recorded professional championship sculling race was in 1831, when one Campbell, Thames waterman, beat one Williams for the championship of the Thames from Westminster to Putney. In 1847 the Putney to Mortlake course was first adopted for these watermen's matches. In 1859 the title first left the Thames, and was won by R. Chambers of the Tyne. About 1850 professional oarsmen were far more numerous than now; and regattas were got up for them, on and off, including four-oar and pair-oar racing as well as sculls. After the 'seventies' these meetings became extinct. In the earlier decades four oars from Tyne and Clyde used to oppose Thames oarsmen. In the present time professionals almost exclusively limit themselves to sculling matches. In sculling, the professional class is far ahead of the amateur, by reason of more leisure for practice. Strength doubtless tells in sculling, but accuracy of blades (for equal and simultaneous immersion and emergence) is the crux; and amateurs have not time to study to obtain this. Besides, most of them are also oarsmen, and work at an oar tends to destroy equilibrium of hands on sculls. In oarsmanship—eights and fours—best amateurs have been, on the other hand, superior to watermen since about 1865. Probably three or four amateur eights could annually be seen which could smother the best watermen's eight of the year (if such a crew were trained and practised).

Decadence of watermen's regattas, coupled with wilful misuse of the true principles of sliding seats, have much to do with deterioration of British professional sculling. From 1876, when E. Trickett, of Australia, beat the then gray-haired J. H. Sadler of Britain, colonials continued to hold the title of world's champion, until, in 1912, at last Ernest Barry brought the title back to Britain, beating R. Armit (New Zealand) on the Thames course. Barry remained unbeaten until 1919, when he suffered defeat at the hands of A. Felton of Australia, but in 1920 he regained the title by defeating Felton on the Parramatta River, New South Wales. Barry thereafter retired. His style was a renaissance of all that is best in sculling—as to slide, combined correctly with swing and level arm work.

'Watermen' on the Thames are a licensed body; but their quondam calling as carriers from river stairs has died out, superseded by rail and road carriage.

Amateur Sculling Championship.—This is symbolised by the 'Wingfield Sculls,' established in 1830. The trophy now carries with it the amateur championship of England. The holder has to meet the best of all challengers once a year, on a date fixed by a committee of old champions, about July, or to abandon in favour of the best challenger.

Regattas.—Henley regatta was founded 1839. In 1886 the course was changed as to some 300 yards of its length, to avoid a corner which gave unfair advantages. It is now a four-days meeting, and comes off early in July each year. The prizes are 'Grand Challenge,' for best eight oars; 'Stewards' Cup,' for best four oars; 'Ladies' Plate,' for college and school eights; 'Thames Cup,' for second-class eights; 'Wyfold Cup,' for second-class fours; 'Visitors,' for college and school fours; 'Silver Goblets,' for any pair of oarsmen; and 'Diamond Sculls,' for single scullers. By first- and second-class eights and fours are meant the classes which usually compete at the races referred to—e.g. no one who rows for 'Grand Challenge' may

row for 'Thames Cup' the same year; nor if 1 row for 'Stewards' fours may he row in a 'Wyfold crew'; the better eights and fours usually elect to do battle for the 'Grand' and 'Stewards', and the weaker reserve themselves for the lesser races. There are other regattas of less importance—e.g. 'Metropolitan,' on the Thames tideway, Kingston-on-Thames, Walton-on-Thames, Monksley, Reading &c.; and provincial regattas at Tewkesbury, Bridgorth, Worcester, Tyne, Durham, Burton-on-Trent, Bedford, &c.

The best regattas are held under the rules of the 'Amateur Rowing Association,' a sort of jockey club of oarsmanship, the object of which is to promote rowing and to put a stop to performance inconsistent with amateur status—e.g. rowing for money prizes. The Amateur Rowing Association publishes a code of regatta rules. All clubs which are affiliated to the Amateur Rowing Association adopt this code. Oarsmen who row at regatta where this code is not in force may become thereby ineligible to row afterwards at regattas where it holds good.

Bumping Races.—In 'bumping' races at the universities the various boats start in line, 120 ft. apart, by signal of cannon. The order of starting depends on order of precedence in the last previous race, whether the same year or the year before.

A boat is touched from behind in the race, both boats row into the bank, and the 'bumped' boat loses a place and changes order next time with the boat that so 'bumped' it. The head boat of the river at Oxford holds a challenge cup given in 1862 by the late Mr G. Morrison.

Time Races.—At Oxford and Cambridge, owing to the narrowness and curvatures of their respective rivers, other races, such as for four oars or sculls, are rowed as 'time' races. The boats start two at a time, 80 yards apart, their respective winning post are the like distance apart, and their respective arrivals at their goals are announced by pistol shots.

Level Racing Rules, &c.—In regattas and matches boats start abreast, and in modern times to ensure equal starting the rudder of each competitor is held from a starting-boat, one for each racing crew moored in line. 'Fouling' is not allowed; each boat has to keep its own water; the umpire is sole judge of the course and of fouling, and usually follows the race in a launch. All boats abide by their accidents—e.g. of broken gear or upsets.

Sliding Seats.—The use of sliding seats began in 1871 in England. Americans had previously used but thought little of the novelties. A Tyne crew, captained by F. Taylor, matched against another Tyne crew, used such seats in a match, November 1871, and won. Next year four Henley crews adopted them with marked success, and the London Rowing Club used them in a winning match v. Atalanta Rowing Club, of New York. In 1873 they became universally adopted. Leading amateur clubs prohibit use of slides by their beginners, till swing on fixed seats has been first mastered, else there is a tendency to sacrifice swing to slide. Slide and swing should begin, continue, and end contemporaneously; the legs should extend gradually as the body swings back, and the sliding seat should on no account touch the back stool until the moment when the oar reaches the chest.

Faults in Rowing.—A 'coach' or tutor of a crew endeavours to cure faults by admonition, so as to get his crew into 'form' and style. Uniformity of oars and of action of bodies has much to do with pace in a racing boat, though, of course, strength is also an important factor. Still a strong oar who mars uniformity among his comrades often does more harm than good, and is well replaced by a lighter and neater oarsman. Among salient

faults may be specified 'rowing out of time,' by letting the oar enter or leave the water too soon or too late; 'rowing light'—i.e. not covering the blade; 'rowing deep'—i.e. burying the shank as well as the blade of the oar; 'feathering under water,' 'sliding too soon' or too suddenly. Among 'faults of swing' are 'hanging' with the body before recovery, or when forward before dropping the oar in; delay in shooting out the hands; 'bending the arms' too soon; bending the back in the middle of the stroke instead of swinging from hips; lurching the shoulders; 'screwing'—i.e. not swinging straight in a line with the keel; 'meeting the oar'—i.e. swinging to meet the oar-handle instead of rowing it well home; 'rowing short'—i.e. not swinging to full reach forward.

Stroke and 'No. 7.'—A 'stroke' is selected to set a good style to the men who are to copy him. Hence style more than rough strength is of importance for this post. A stroke should be lively in swing; sharp in catching hold of the first part of the stroke; long in reach; even in swing; even in time, like a pendulum; a good judge of the pace of stroke which he is rowing; capable of 'spurring'—i.e. of quickening the pace of stroke when extra speed is needed, and this without getting short in reach. Thirty strokes a minute is a fair practice stroke. In racing for a mile or mile-and-half course as many as forty-four a minute can be rowed long by good crews. Over a four mile course thirty-seven a minute, well rowed at full length of reach, is about as much as can be done, excepting a final 'spurt.' 'No. 7' is second to none in importance in an eight oar. He copies stroke to the crew. A weak No. 7 takes many points of merit off a crew, and cripples the work of good but rough men behind him.

Steering.—Four oars are now rowed without coxswains, except in junior or second-class races. One of the oarsmen steers with levers attached to his stretcher and connected with the rudder by wires. In an eight, a coxswain is an important factor; he should have nerve and judgment, and be capable of reminding his crew of faults, when, as in a race, no 'coach' or mentor can attend them. The main art in steering is to keep the boat in a straight course by gentle touch and adjustment of the rudder lines, not by hard pulls, which tend to spoil equilibrium, and to bring the boat round too sharply. In going round a curve the bows should not be expected to point in the direction required. They must of necessity point outwards, because the boat lies as a tangent to a curve.

Rowing Clubs.—Among leading amateur rowing clubs, besides the universities, may be mentioned the Leander, the London Rowing Club, Thames Rowing Club, Kingston, Molesey; these usually supply the competitors at Henley, together with the universities. There are good provincial clubs at Durham, Worcester, Bridgorth, Bedford, Huntingdon, Burton, &c. Among schools Eton, Ladley, Westminster, Shrewsbury, Cheltenham, Bedford 'Grammar' and Bedford 'Modern' supply good oarsmen—Eton especially. Of university crews, nearly one-half are made up on the average of 'old Etonians.'

Training.—'Condition' promotes endurance in contest, whether of horse or man. Hence training is an important item in preparation for a boat-race. Hard work trains; regulated diet keeps the oarsman up to this hard work, and puts on extra muscle to replace fat which hard work has sweated off. Five weeks is a minimum time for full training where oarsmen have been out of work for some time; a shorter period may suffice if they have not been inactive for long. Professionals usually train for three months before a match. The usual rules are early rising—say 7 A.M.—a

short morning walk, bath, breakfast, morning row (if studies or business hours admit of it), luncheon or midday dinner, afternoon or evening row (according to season of year), late dinner or supper, a short post-prandial stroll, a cup of gruel or chocolate, and bed for nine hours. After each row the body should be well washed and rubbed down. As to diet. For breakfast: fish, eggs, watercress or lettuce; and two cups of tea; stale bread or toast. For luncheon: cold meat and some green food; or broiled meat and vegetables. Dinner: fish; joints of beef or mutton; vegetables—any greens, asparagus, spinach, a potato or two, &c.; now and then a modicum of poultry as an extra course; stewed fruit; rice or plain farinaceous pudding. Drink: at luncheon or dinner, ale, or light wine. A pint at each meal usually suffices; in sultry weather a little more fluid may be allowed, in which case it is best to let the extra supply be water only. Oranges or strawberries are allowed for dessert, and a glass of port. Pork and veal are tabooed, as being indigestible in the large quantities which hungry men consume. Such is modern training. In earlier decades less liberality was allowed. Steaks, chops, and plain joints formed the staple supplies, and the hobby was to have them 'underdone,' almost to semi-rareness. This system often produces disorder of blood, resulting in boils, the effect of too much animal food without sufficient green meat. Professionals still adhere to old creeds of training more tenaciously than do modern amateurs.

Boats, Oars, and Pace of Races.—The boats used for racing have been gradually evolved from the old pleasure craft. The ship in which Oxford won the first Oxford and Cambridge Boat Race is still preserved by the O.U.B.C. She is simply an elongated fixed-seat, irrigated gig, and is 'clinker-built,' i.e. built of narrow planks, each of which overlaps the next. After the introduction of outriggers, racing-boats were made much narrower and longer, but the greatest step in the evolution of racing craft was the introduction of the keelless boat. All modern racing-boats are keelless, i.e. the timber which takes the place of the keel (called the 'kelson'), and runs the whole length of the boat, is inside the outer covering or skin. A racing-boat is built upside down. First the timbers which take the place of the gunwale (now called the inwale) are placed in position on the bench. On this inwale are placed, at fixed intervals, the ribs fixing it to the kelson, which is then placed in position. At this stage the boat somewhat resembles a skeleton. The skin of thin cedar is then superimposed and attached to the ribs with copper nails. Before being thus fitted the cedar planks are cut exactly to the required size. They are moistened on one side and heated on the other so as to make them curve, and are fixed in position before they have time to regain their normal shape. By this process the hull of the boat, when completed, is absolutely smooth and without excrescence of any kind. The hull is then turned over, and the seats, stretchers, sax-boards (running along the top of the side), and outriggers fixed. A complete racing eight is a beautifully finished piece of cabinet work, and costs approximately £110 to £120.

In spite of many arguments and discussions as to the correct lines for the longitudinal and transverse sections of a racing-boat, there has been no very great change since 1875. An eight is pointed at bow and stern, is about 60 feet long, has its greatest beam (about 23 inches) at No. 4's seat; it gets very gradually narrower from that point to 'stroke's' seat, and then tapers off to a point at the stem. The leverage of the oars, measured from the centre of the seat to the rowlock, is 31 inches. The slide comes level with the rowlock when the oarsman is

fully extended forward, and travels back about 16 inches. Racing oars range from 12 feet to 12 feet 4 inches in length; the button is 3 feet 8 inches from the handle, and the blades from 5½ inches to 7½ inches wide.

There have from time to time been improvements in the manufacture and fitting of racing-boats, and in the material and construction of oars, but they have not had any very marked effect on the time records of competing crews. Between Putney and Mortlake the sloping banks of the river have been gradually replaced by vertical concrete embankments, and the tide runs faster now than it formerly did. As a result, the times occupied by the university crews, both in practice and in the race itself, have improved; but at Henley Regatta the record time for the Grand Challenge Cup (6 min. 51 sec.) made in 1891 by Leander Club, and in 1897 by New College, Oxford, has not been beaten. Making all due allowances for conditions of weather and stream, it is believed that the fastest piece of eight-oared rowing ever accomplished was in the race between the United States (Naval College) and Great Britain (Leander Club) at the Olympic Regatta of 1920. The Americans won by four-fifths of a second, and their time over 2000 metres was 6 min. 5 sec. The race was rowed at Villevorde on the Antwerp-Brussels canal.

Rowlandson, THOMAS, caricaturist, was born in the Old Jewry in July 1756. He was sent to Paris at fifteen, and there he studied art and gained a taste for the pleasures of the town. The over-indulgence of a wealthy French aunt first taught him improvidence, and the £7000 she left him he quickly gambled away, once continuing at the gaming-table, we are told, for thirty-six hours continuously. Yet he maintained his uprightness of character, hated debt, and when he had played the fool turned to his work as his resource. He travelled over England and Wales, often visited Plymouth, Portsmouth, Southampton, and especially Yarmouth, and, being a humorist to the marrow, enjoyed life to the full in his tavern, with his tankard and his pipe, and the company of friends like Moreland, Gilbray, and Banbury. He died April 22, 1827. Rowlandson took little pains over his work, yet his drawings never lack the essential elements of his strength, variety, and humour. He possessed rare dexterity of touch, fertility of imagination, and knowledge of the human figure, and, though he was not seldom vulgar, he was never feeble. He was a relentless hater of Napoleon to his fall, belittling his greatness by countless travesties; and though he took his part in many of the political contests of his day, he was never a mere party satirist. His strength lay in broadly human humour, as seen at its richest among the lower orders of the population, as in his famous Vauxhall drawing. Well known are his *Imitations of Modern Drawings* (1784-88), and his illustrations to *Dr Syntax's Three Tours*, *The Dance of Death*, *Johnny Newcome*, *Sterne's Sentimental Journey*, *Peter Pinder*, *The Bath Guide*, and *Manchhausen's Travels*. See **CARICATURE**, and books by Grego (1880); and A. P. Oppé (1923).

Rowley, THOMAS, the pretended monk on whom Chatterton fathered the 'Rowley Romance'; see **CHATTERTON**.

Rowley, WILLIAM, an actor and playwright under James I., of whose life but little is known,

save that he was honoured by collaborating with such illustrious dramatists as Dekker, Middleton, Heywood, Webster, Massinger, and Ford, most probably for his skill in stage situation. Four plays published with his name are extant: *A New Wonder, a Woman never veat* (1632; and in Dodsley); *All's Lost by Lust* (1633; ed. Morris, 1907; Stork, 1910); *A Match at Midnight* (1633); and *A Shoemaker a Gentleman* (1638; ed. Stork).

Rowley Regis, a town of Staffordshire, 3 miles S.E. of Dudley. Four parish churches in succession have occupied the same site (1199, 1840, 1904, 1923). There are collieries, ironworks, stone-quarries, potteries, implement-works, &c. Pop. (urban district) 40,000.

Rowton Heath, a battle of the Great Rebellion, fought under the walls of Chester, 24th September 1645. After the crushing disaster of Naseby the king fled to Wales, and next formed the desperate project to march northwards to Montrose. The city of Chester was then being besieged by Sir William Breton, but the king succeeded in finding an entrance, and charged Sir Marmaduke Langdale to raise the siege. The parliamentarians had just been reinforced by Poyntz's Yorkshire Horse when Sir Marmaduke attacked them. He was utterly defeated, with a loss of 300 killed and 1000 prisoners, and the disaster, added to Philiphaugh, stripped the king of his last hope.

Roxburgh. WILLIAM (1759-1815), botanist, born at Underwood, Ayrshire, was appointed director of the Calcutta Botanical Gardens in 1793. His books, *Plants of the Coast of Coromandel* and *Flora Indica*, made him a recognised authority on Indian botany. The family Roxburghiaceæ was named after him by Sir Joseph Banks.

Roxburgh Club. See BOOK-CLUB.

Roxburghiaceæ. See STEMONACEÆ.

Roxburghshire, a Scottish Border county, bounded by Berwickshire, Northumberland and Cumberland, Dumfriesshire, Selkirkshire, and Midlothian. Its greatest length is 42 miles; its greatest breadth 30 miles; and its area 670 sq. m., or 428,494 acres. In the north the Tweed winds 25 miles eastward, receiving in this course the Leader and the Teviot, which latter runs 37 miles north-eastward from above Hawick to Kelso, and itself receives the Ale, Slitrig, Rile, Jed, &c. Thus the whole county, often called Teviotdale, drains to the German Ocean, with the exception only of Liddesdale, or Castleton parish, in the extreme south, whose 106 sq. m. belong to the basin of the Solway Firth. The Cheviots (q.v.) extend along the south-eastern boundary, their highest point here Aulopcairn (2382 feet); in the interior rise Ruberslaw (1392) and the triple Fildons (1385). Much of the low ground is of fair fertility, and great improvements have been made in agriculture; but rather less than two-thirds of the entire area is in cultivation, and the raising of crops is of much less importance than the grazing of sheep. Roxburgh, which gave the county its name, has been quite superseded by its neighbour Kelso (q.v.); and Jedburgh, the county town, is very much smaller than Hawick; other places are Melrose, Denholm, St Boswells, Yetholm, &c. Chief seats are Floors Castle, Monnt Teviot, Minto House, and Abbotsford; and the dukes of Buccleuch and Roxburgh are much the largest proprietors. The antiquities include hill-forts; the Catrail; Dere Street; the Roman station at Newstead; the castles or peel-towers of Hermitage, Branxholm, Harden, Ferniehirst, Snailholm, &c.; and the noble monastic ruins of Melrose, Jedburgh, and Kelso. Besides many more worthies, five poets—James Thomson, Jean Elliot, Leyden, Aird, Pringle—were natives; but, although not his birthplace, Roxburghshire is

pre-eminently the land of Scott. It witnessed many a fray, but no battle greater than Auncun Moor (q.v.). The county returned one member to parliament till 1918; since then one in conjunction with Selkirkshire. Pop. (1801) 33,721; (1831) 43,663; (1861) 54,119; (1891) 53,741; (1921) 44,989.

See Jeffrey's *History of Roxburghshire* (1857-64); Sir G. Douglas, *Roxburgh, Selkirk, and Peebles* (1899); Sir James Murray, *Dialect of the Southern Counties of Scotland*; G. Watson, *Roxburghshire Word-book* (1923); W. S. Crockett, *Berwickshire and Roxburghshire* (1926); and BORDERS, BALLAD, HAWICK, TWEED, MELROSE, &c.

Roxbury, was annexed in 1867 to Boston (q.v.).

Roy, WILLIAM, the first of British geodesists, was born 4th May 1726, at Miltonhead, in Carlisle parish, Lanarkshire, his father being factor and gardener to the Hamiltons of Hallerail. He was educated at the parish school and Lanark grammar-school, and in 1747 is found acting as deputy-quartermaster in the Royal Engineers corps, engaged on the survey of Scotland. His name first figures in the *Army List* in 1757, and he gradually rose to be lieutenant-colonel (1764), colonel (1777), and major-general (1781). In 1784 he measured a base line (see ORDANCE SURVEY) on Honnslow Heath of 27,404 feet, or about 5½ miles, which, though the first measurement of the kind in Britain pretending to accuracy, was executed with such care that, on remeasurement after Roy's death, the difference between the two results was found to be only 2½ inches. For this splendid labour Roy received the Royal Society's Copley medal. Ill-health necessitated his removal to Lisbon in the winter of 1789; but he returned to London, and died there suddenly, 30th June 1790. In 1767 Roy was elected a Fellow of the Royal Society, to whose *Transactions* he contributed, in 1777, 'Experiments made in Britain to obtain a Rule for Measuring Heights with the Barometer.' He had also during survey-work in Scotland (1764) paid particular attention to the camps and other Roman remains in that country, and his *Military Antiquities of the Romans in Britain* was published in 1793 by the Society of Antiquaries. Roy was also surveyor-general of the coasts of Great Britain.

See two articles in the *Proc. Soc. Antiquar. Scot.* (i. p. 147, 1856; and ix. p. 562, 1873).

Royal Academy. In 1745 Hogarth and other painters, with the view of making their works known, presented certain of them to the Foundling Hospital. The public having been greatly attracted, they, in 1760, opened a free exhibition in the rooms of the Society of Arts; and, in the following year, a series of exhibitions was begun in Spring Gardens, and its promoters, styled 'The Incorporated Society of Artists of Great Britain,' received a royal charter in 1765. Disputes having arisen, twenty-nine members of this society (not—according to Redgrave—twenty-two only, as stated by Sandby) memorialised George III. to establish an academy for the encouragement of the arts of design, and the plan they submitted having been approved, the 'Royal Academy of Arts in London' was founded, 10th December 1768. The instrument of foundation provided for forty academicians, from whom the president and other officials, including professors of fine art in its various branches, should be elected; and annual exhibitions were stipulated for, their proceeds to be devoted to the aid of indigent artists and to the support of the Academy. In 1769 a class of twenty associates (to have no share in the government of the body, a restriction since modified) was created, and also a class of six associate-engravers, on the same footing, excepting that they were ineligible for election as academicians, a restriction now withdrawn. In 1771 George III. assigned rooms to the

academy in Somerset House, and during twelve years (1768-80) he contributed £5116 to its funds from the privy purse; after 1780 the help became unnecessary. In 1837 it removed to quarters in the National Gallery, and in 1867 obtained a lease of Old Burlington House. As tersely stated by Redgrave, 'the strength of the new institution consisted in its combining, under a well-framed code of laws, the most esteemed artists of the day, empowered to manage their own affairs.' The thirty-nine named in the instrument, include Reynolds, Gainsborough, Wilson, and ten foreigners; Sir Joshua was elected the first president. See Sandby, *History of the Royal Academy* (1862); Hodgson and Eaton, *The Royal Academy* (1905); A. Graves, *The Royal Academy* (a dictionary, 6 vols. 1904-6); and for the Chantry Fund, CHANTREY.

The Royal Hibernian Academy, founded by charter in 1823, consists of twenty-five academicians and eight associates. Its first president, Francis Johnston, presented ground and erected buildings thereon for the use of the body. The Academy suffered badly in the rebellion of 1916.

The Scottish Academy, the successor of such exhibiting bodies as the society of 'Associated Artists' and the Royal Institution, was founded in 1826, under the presidency of George Watson, consisting of thirty academicians and sixteen associates (the latter increased in 1830 to twenty). In 1838 it received a charter, entitling it to the style of 'The Royal Scottish Academy of Painting, Sculpture, and Architecture'; and in 1891 a supplementary charter was granted, admitting associates to a share in the management of the body, and removing any limit to their numbers (but providing that only twenty shall participate in the pension fund), and granting extended powers for dealing with non-resident and non-exhibiting members. See Sir G. Harvey's *Notes of the Early History of the Royal Scottish Academy* (2d ed. 1873).

Royal Academy of Music. The name first given in England to an association for performing operas, mainly those of Handel, founded by the king and the principal nobility and gentry of the country, which survived for but a few years. The well-known educational institute now bearing the name was founded in 1822 by Lord Broughsham (1784-1859, afterwards eleventh Earl of Westmorland, and not less distinguished as a musician than as soldier and diplomatist), who saw with regret the great disadvantages under which natives of Great Britain suffered as compared with those of foreign countries in respect of musical education. The institution, which received a charter in 1830, was designed to give concerts as well as to provide musical education; and it has instructed many of the leading instrumentalists and vocalists of both sexes. Since its reconstitution in 1866 the most distinguished principals have been Sir George Macfarren (1876-87), Sir A. C. Mackenzie (1888-1924), and John McEwen. The Royal Academy of Music is distinct from the Royal College of Music (see CONSERVATOIRE), though allied with it for promoting musical education throughout the country by means of an 'Associated Board.' The Royal College of Organists dates from 1864. It received a royal charter in 1893, and was accommodated in its present buildings (Kensington Gore) in 1904.

Royal Assent. See PARLIAMENT; and for royal prerogative, &c., see SOVEREIGN, WARRANT, SUPREMACY, COMMISSIONS, CHARGE, BOUNTY, HOUSEHOLD, HUMANE SOCIETY, HERALDRY, CIVIL LIST, SOCIETIES.

Royal Family. By the law of England royal rank is conceded to the wife or husband, children or other descendants, and collateral relatives of the

sovereign. For the position and rights of a Queen-consort or Queen-dowager, see the article QUEEN. The husband of a reigning queen does not acquire any share in her prerogative rights, but it is usual to grant him special precedence; King Philip and William III. were associated in title and power with their wives by act of parliament. Of the sovereign's children the eldest son is, of course, heir-apparent; he is born Duke of Cornwall, and he is always created Prince of Wales (q.v.). The Prince and Princess of Wales and the Princess Royal (the eldest daughter of the sovereign) are within the protection of the statute of Edward III. relating to Treason (q.v.). An heir-presumptive to the throne has no special rank or precedence as such. The younger children of the sovereign take rank after the heir-apparent; by a statute of 1540 a place is assigned to them at the side of the cloth of estate in the parliament chamber; it is customary to confer peerages on all the younger sons. On a reference by George II. to the House of Lords it was held that Edward, Duke of York, second son of the Prince of Wales, was entitled to a place among the king's children. Members of the royal family enjoy considerable privileges; they pay no tolls or duties, and they are exempted from succession duty and some other taxes.

In order to protect the succession to the crown against the dangers which might arise from unsuitable alliances, the following special rules are applied to members of the royal family: (1) by the Royal Marriage Act of 1772 it is enacted that no descendant of George II. (other than the issue of princesses married into foreign families) may marry without the consent of the sovereign; any marriage contracted without such consent is void. But any such descendant, if above the age of twenty-five, may, after twelve months' notice to the Privy-council, contract marriage without such consent, unless both Houses of Parliament declare their disapproval. All persons who solemnise or are present at a marriage contrary to the act are liable to the penalties of *Premunire* (q.v.). The act was passed in consequence of the marriage of the Duke of Gloucester with the widow of Lord Waldegrave and of the Duke of Cumberland with the widow of Colonel Horton. In 1793 the Duke of Sussex was married at Rome to Lady Augusta Murray; the marriage was declared void by the Prerogative Court, and the claims of Sir Augustus d'Este, eldest son of the marriage, were rejected by the House of Lords in 1844. (2) The grandchildren of the sovereign (not being the issue of princesses married to foreigners and residing abroad) are under the control of the sovereign, who may order the place of their abode, without regard to the wishes of their parents. The law was so laid down by a majority of the judges in the case of the children of Frederick, Prince of Wales, in 1737. The policy of these rules has been much questioned, and the conduct of George IV. in regard to his marriage with Mrs Fitzherbert (q.v.) in 1785 affords a strong argument against the existing law. See also CIVIL LIST.

Royal Fern (*Osmunda*), the most striking of British ferns; it grows in damp places, and used to be fairly common in districts of a very moist climate in Scotland and Ireland, but is disappearing before collectors. It has two kinds of leaves, sterile and fertile; the sterile are bipinnate; the fertile, covered with spore-cases, have the appearance of a panicle inflorescence, due to the absorption of the central tissues—hence the name Flowering Fern. The genus is allied to another, *Todea*, which has only one kind of leaf, and the two are included in the *Osmundaceæ*. There are only a very few species. The spores give rise at once to the prothallus without the intervention

of a protonema; and the prothalli tend to be unisexual—i.e. to have the male and female

Royal Fern (*Osmunda regalis*):
a, leaflet of barren frond; b, portion of fertile frond.

organs on separate plants; or the male organs appear on the prothallus before the female.

Royal George. See WRECKS.

Royal Institution, founded in 1799 by Count Rumford, Sir Joseph Banks, and others, received a royal charter in 1800, and had for its objects the facilitating of mechanical inventions, the promotion of their use, and the teaching of science and its applications by means of lectures and experiments. It was reconstituted in 1810. Among its lecturers have been many of the most eminent English men of science. It maintains professors of natural philosophy, chemistry, and physiology, and has laboratories (including since 1896 the Davy-Paraday research laboratory presented by Dr Ludwig Mond).

Royal Military Asylum, commonly called the 'Duke of York's School,' an institution for educating the sons—generally orphans—of British soldiers, was established at Chelsea in 1801-3 by the Duke of York, but transferred in 1909 to Gaston, near Dover. The boys have a completely military organisation, with scarlet uniform, band, &c. A similar institution is the Queen Victoria School at Dunblane. As a result of their training a large proportion of the pupils ultimately volunteer into the army; and the military bands are largely recruited from these schools. See MILITARY SCHOOLS, BAND.

Royal Society. The origin of this society may be traced back to those stirring years of civil strife that brought in the Commonwealth. Clubs for political, theological, and sectarian purposes, were then numerous and active; and in the year 1645 'divers worthy persons, inquisitive into natural philosophy, and other parts of human learning, did, by agreements, meet weekly in London on a certain day, to treat and discourse of such affairs.' Among these worthy persons were certain medical men, Dr Wilkins, afterwards Bishop of Chester; Foster, professor of astronomy in Gresham College; Wallis, the mathematician; and others, including Hank, a learned German from the Palatinate; and out of their meetings arose the now world-famous Royal Society. Wallis records that the subjects discussed of were 'the circulation of the blood; the valves in the veins; the venæ lacteæ; the lymphatic vessels; the Copernican

hypothesis; the nature of comets and new stars; the satellites of Jupiter; the oval shape of Saturn; the spots in the sun, and its turning on its own axis; the inequalities and selenography of the moon; the several phases of Venus and Mercury; the improvement of telescopes, and grinding of glasses for that purpose; the weight of air; the possibility or impossibility of vacuities, and nature's abhorrence thereof; the Torricellian experiment in quicksilver; the descent of heavy bodies, and the degrees of acceleration therein; and divers other things of like nature.' In 1662 the persevering 'philosophers' (as students of the mathematical and natural sciences were then usually called) were, through the 'grace and favour' of Charles II., incorporated by charter, in which they were described as the Royal Society of London for the Promotion of Natural Knowledge. The king gave them also a mace, and subsequently granted two other charters conferring additional powers and privileges. They are inscribed in a handsome volume known as the Charter Book, which, containing, as it does, the sign-manual of the founder, of other royal personages, and of nearly every Fellow elected into the society, presents a collection of autographs unequalled in the world.

Through many difficulties the young society pursued its way. Its meetings were interrupted by the plague and the great fire; but in March 1661-65 it had published the first number of the *Philosophical Transactions*, and thus commenced a record of its labours and researches, and at the same time a history of science of the highest value. Besides this, the society has published since 1800 an octavo serial entitled *Proceedings*. The *Catalogue of Scientific Papers* contains the titles of scientific papers published in all parts of the world from 1800 to 1900. In 1901 its place was taken by the *International Catalogue of Scientific Literature*, the publishing of which is in the hands of the Royal Society. The society's publications are not restricted to the Fellows, but are sold to the general public. By increase of numbers—including scientific men on the Continent, who were elected as foreign members—the society widened its sphere of usefulness. It promoted the publication of Newton's *Principia* and optical works; it lent instruments to Greenwich Observatory in its early days, and its Fellows were appointed visitors of that establishment by Queen Anne a function which they still exercise; it aided travellers and scientific investigators; advised the government on scientific subjects; Cook's celebrated voyage to observe the transit of Venus was undertaken at its instance; and since the voyage of the *Endeavour* many scientific expeditions have been equipped under the advice of the Royal Society. In 1710 the society removed to a house which it bought in Crane Court, Fleet Street. In 1780, by order of George III., quarters were assigned to it in the then new palatial building, Somerset House. In 1857, at the request of the government, it migrated westward to Burlington House, a wing of which it now occupies.

Various bequests and gifts (including £100,000 from Sir Alfred Yarrow) enabled the society in 1922 and 1923 to establish a number of research professorships in order that men of ability of the highest type should be able to give their whole time to research. The society sends two representatives to the Meteorological Committee, and otherwise controls certain departments of meteorological research, while, from its inception in 1902, the National Physical Laboratory has been under its scientific control. In fulfilment of trusts the society awards annually, in recognition of scientific work and discoveries, several medals, including the Copley medal and two Royal medals; the Rumford medal every two years for researches in

light or heat; the Darwin medal for biological research; and the Davy medal for chemical investigations. Some of the most illustrious names in the annals of science appear on the roll of presidents of the Royal Society. See the *Record of the Royal Society* (3d ed. 1912) and the society's *Year-book*; and for the two dining clubs (amalgamated in 1901), the *Annals of the Royal Society Club* (ed. Sir A. Geikie, 1917), and *Annals of the Philosophical Club of the Royal Society* (ed. T. G. Bonney, 1919).

The ROYAL SOCIETY OF EDINBURGH, which took the place of the Philosophical Society of that city, was incorporated by royal charter in 1783. It owed its origin to Principal Robertson the historian, who successfully laboured to found in Edinburgh a society on the model of the Berlin Academy, for the investigation and discussion of subjects in every branch of science, erudition, and taste. In obtaining the royal charter the Principal was aided by the influence of Henry, Duke of Buccleuch, who zealously co-operated in the foundation of the society. The society was formally constituted at a meeting held in the College Library on the 23d June 1783, where the subsequent meetings were held till 1810, when the society purchased a house in George Street. In 1826 the society

list of members included the names of most of the literati of Scotland—such as David Hume, Unguid Stewart, Henry Mackenzie, Adam Smith, Thomas Reid, Joseph Home, Sir James Hall, Joseph Black, James Hutton, and James Watt. The first president was Henry, Duke of Buccleuch; and amongst his successors have been Sir Walter Scott, the Duke of Argyll, Sir David Brewster, Lord Kelvin, Sir William Turner, Professor James Geikie, Dr John Horne, and Sir Alfred Ewing.

The papers read are published in the society's *Transactions*, and in its *Proceedings*. It has an extensive library consisting mainly of scientific serials of all countries. There are some valuable prizes, which are bestowed on the authors of the best communications on scientific and other subjects. These are the Keith Prize, founded by Alexander Keith of Dunnottar; the McDougall Brisbane Prize, by Sir Thomas M. Brisbane; the Neill Prize, by Dr Patrick Neill; the Gunning Victoria Jubilee Prize, by Dr R. H. Gunning; the James Scott Prize, and the Buce Memorial Prize. See the history of the society in Neill's index to the *Transactions*.

Royalty, originally the seigniorage paid to the crown for a manor of which the king is lord, or a tax paid to the king for lands or to a superior as representing the crown; but most familiar nowadays in two derived senses of modified signification. Royalty is the term for the sum paid on minerals removed from a mine, not necessarily to the crown, but to the landlord, on the theory that the landlord owns the soil to the centre of the earth, and accordingly all the minerals found beneath his land (see MINING). This burden is by many regarded as a grievance, and its abolition advocated. Another sense of the word is the sum paid to the holder of a patent, by percentage for each article manufactured under the patent, or for the use of patent articles hired out by the patentee (see PATENT). Another is the sum paid from time to time by a publisher to an author, calculated on the number of copies sold (see BOOK-TRADE, COPYRIGHT).

Royan, a small seaport of France (dep. Charente-Inférieure), stands on the north side of the estuary of the Gironde, 60 miles N.W. of Bordeaux. It is one of the most frequented seaside places on the Atlantic coast of France. Pop. 10,000.

Roy Bareilly. See RAI BAREIL.

Royden, AGNES MAUDE, preacher, was born in 1876, the youngest daughter of Sir Thomas Royden, first baronet of Frankly Hall, Birkenhead. Educated at Cheltenham Ladies' College and Lady Margaret Hall, Oxford, she thereupon allied herself closely with the women's movement. She lectured in English literature to the Oxford University Extension Delegacy, and edited the *Common Cause* till 1914. In 1917 she became assistant preacher at the City Temple, and in 1920 began services at Kensington.

Royer-Collard, PIERRE PAUL, a French statesman, was born 21st June 1763, at Sompuis (dept. Marne). On the outbreak of the Revolution he was elected a member of the municipality of Paris, and from 1790 to 1792 acted as joint-secretary. Having incurred the enmity of the Jacobins, he lived in hiding at Sompuis during the Reign of Terror. Three years afterwards (1797) chosen to the Council of the Five Hundred, he took an active part in the work of that assembly, until the 18th Fructidor. In 1811 he was appointed professor of Philosophy in Paris, and exercised an immense influence on the philosophy of France. Rejecting the purely sensual system of Condillac, he proceeded eclectically, giving special prominence to the principles of the Scottish Philosophy (q.v.) of Reid and Stewart. Strongly 'spiritualist' as opposed to materialism, he originated the 'Doctrinaire' school, of which Joffroy and Cousin were the chief representatives. He was appointed president of the Commission of Public Instruction in 1815, but resigned that post in 1820; in 1815 also he returned to political life as deputy for the department of Marne. The French Academy opened its doors to him in 1827; and in 1828 he was named president of the Chamber of Representatives, and in that capacity presented the address of the 221 deputies (March 1830) withdrawing their support from the government, which the king refused to hear read. Next day the Chamber was prorogued. From 1842 Royer-Collard completely withdrew from public life; he died, 4th September 1845, at his country seat of Châteauneuf, near St Aignan (Loir-et-Cher). His salon was latterly the resort of such men as Cousin, Guizot, De Broglie, Casimir Périer, Villmain, De Rémusat, and others. He never was a writer, and he became a philosopher only by accident: his true interest in life was politics, his real eminence as a political orator after the ancient pattern, rather than that of the modern parliamentary debater. His idea of the monarchy was utopian; the famous *charte* was found impracticable as the sheet-anchor of liberty; even his best speeches, triumphs of dialectic as they often were, fell short of the effect that seemed secure, whether because ever in human things facts overturn the conclusions of reason, or because reason does not reach the profound depths in which are generated the opinions of men.

See biographies by Philippe (1857), De Barante (new ed. 1878), and Spuller (1895); R. de Nesmes Desmonets, *Les Destinées politiques de Royer-Collard* (1908); Schérer's *Études sur la Litt. Contemp.*, vol. 1., and Faguet, *Politiques et Monarchistes du XIX^e Siècle* (1891).

Royston, an urban district of Hertfordshire, 20 miles north of Hertford. There is an ancient church (1250-80), and in the middle ages the Austinian canons had a priory here. In 1742 a cavern was discovered under one of the streets. It is said to date back to before Roman times and to have served later as a sepulchre, a hermitage, and an oratory. Pop. 4000.

Royston, a town of Lancashire, 2 miles NNW. of Oldham, with large cotton-factories; pop. 17,000.

Rsheff, or RJEV, a town of European Russia, on the Volga, 135 miles NW. of Moscow, is a river-port; pop. 25,000.

Ruabon, a town of Denbighshire, $\frac{1}{2}$ miles SSW. of Wrexham, with collieries and brickworks; pop. 3600.

Rubasse, a mineral prized for ornamental uses, is rock-crystal, limpid or slightly amethystine, filled internally with minute brown spangles of specular iron, which reflect a bright red, equal to that of the most brilliant ruby. An artificial rubasse is made by heating very pure rock-crystal red hot and plunging it into a coloured liquid.

Rubber. See INDIA-RUBBER.

Rubble, a common kind of masonry, in which the stones are irregular in size and shape. Walls faced with ashlar are generally packed with rubble at the back. Rubble is of various kinds, according to the amount of dressing given to the stones. Common rubble is built with stones left almost as they come from the quarry. Hammer-dressed rubble is so called when the stones are squared with the mason's hammer; coursed rubble, when the stones are squared and equal in height, &c.

Rubefacients are external agents employed in medicine for the purpose of stimulating, and consequently reddening, the part to which they are applied. All agents which, after a certain period, act as Blisters (q.v.) may be made to act as rubefacients if their time of action is shortened. The mildest rubefacients are hot poultices, cloths soaked in very hot water, moderately stimulating liniments—as, for example, soap liniment, with various proportions of liniment of ammonia, or chloroform, &c. Spanish fly, in the form of *Emplastrum Calefaciens*, or warm plaster, in which the active ingredient is blunted by the free admixture of soap-plaster, resin-plaster, &c., is a good form of this class of agents. Capsicum or Cayenne pepper, in the form of an ointment, is an excellent rubefacient; it is much used in the West Indies, but is seldom employed in this country. Mustard, in the form of *Cataplasma Sinapis*, or mustard poultice, and oil of turpentine are perhaps the best of the ordinary rubefacients. The former is applied to the chest, with much advantage, in many cases of pulmonary and cardiac disease, such as bronchitis, pneumonia, &c., and to the surface of the abdomen in various affections of the abdominal viscera. Mustard is also used by mixing with hot baths for the feet in cases of catarrh, or in general baths as a stimulant to the whole skin. The best method of employing turpentine is to sprinkle it freely on three or four folds of clean flannel, wrung out of boiling water. The sprinkled surface of this pad is placed upon the skin, and a warm dry towel is laid over the flannel. Two or three such applications will produce a powerful rubefacient effect. Turpentine thus applied is serviceable in all the cases mentioned in the above remarks on mustard, as well as in sore throat, chronic rheumatism, neuralgia, &c.

Rubella, or GERMAN MEASLES. See MEASLES.

Rubens, PETER PAUL, the most celebrated painter of the Flemish school, was born on the 28th of June 1577 at Siegen, in Westphalia, where his father, John Rubens, an eminent lawyer, was living in disgrace, in consequence of his intrigue with Anne of Saxony, second wife of William the Silent. In 1578 his parents settled in Cologne; and upon the death of her husband in the year 1587, his mother returned to her native city of Antwerp, where the boy was educated in the Jesuits' college. He served for a short time as a page in the household of Margaret de Ligne, widow of the Count of Lanaing, and was intended for the pro-

fession of law; but he was animated by a strong desire to become a painter, and at the age of thirteen he began the study of art, first, for a brief period, under Tobias van Haeght, a skilful landscape-painter; then for four years under Adam van Noort, a painter of religious subjects, distinguished for his excellent colouring; until finally, in his nineteenth year, he passed into the studio of Otho van Veen, court-painter to the Archduke Albert, governor of the Netherlands.

In 1599 he was admitted a master of the Brotherhood of St Luke in Antwerp; and in the following year he started for Italy, making his way to Venice, where he studied the works of Titian and Veronese. He next entered the service of Vincenzo Gonzaga, the magnificent and luxurious Duke of Mantua, as gentleman of the chamber and court-painter; and in 1605 was despatched on a mission to Philip III. of Spain, thus beginning the career of a diplomatist, for which his keen intellect, his polished urbanity, and his linguistic attainments so admirably qualified him. While at Madrid he executed portraits of many of the Spanish nobility, as well as several historical subjects. On his return from Spain he travelled in Italy, copying celebrated works for the Duke of Mantua; and to this period is referable the sketch, now in the National Gallery, London, from one of the subjects of Mantua's 'Triumph of Julius Caesar.' In 1608, while in Genoa, he received news of his mother's illness, and returned home, but too late to see her alive. Settling in Antwerp, he was appointed in 1609 court-painter to the Archduke Albert and his wife Isabella, and soon afterwards married his first wife, Isabella Brant, whom his pencil has often portrayed, and who appears, seated hand in hand with himself, in the famous full-length group at Munich.

The painter was now rapidly approaching his full artistic maturity, and his 'Descent from the Cross,' in the cathedral of Antwerp, begun in 1611 and completed in 1614, and usually regarded as his masterpiece, is a work in which both his earlier and later manner may be traced. It is a triptych, showing on the interior of its wings The Visitation and The Presentation in the Temple, and on their exterior subjects of St Christopher and a Hermit bearing a lantern.

In 1620 Rubens was invited to France by Marie de' Medici, the queen-mother, who was then engaged in decorating the palace of the Luxembourg in Paris; and he undertook for her twenty-one large subjects commemorating her marriage to Henry IV., works, completed with the aid of assistants in 1625, which are now in the Louvre, most of the sketches by the master's own hand being at Munich. In 1628 he was despatched by the Infanta Isabella upon a diplomatic mission to Philip IV. of Spain. He remained for nine months in Madrid, and there he made the acquaintance of Velasquez, and executed some forty works, including five portraits of the Spanish monarch. In 1629 he was appointed envoy to Charles I. of England, to treat for peace; and, while he conducted a delicate negotiation with perfect tact and success, his brush was not idle, for he painted the 'Peace and War,' now in the National Gallery, London, and the portrait of the king and his queen as St George and Cleopatra, a work now at Windsor, and also made sketches for the Apotheosis of James I. for the Banqueting-hall at Whitehall, completing the pictures on his return to Antwerp. In acknowledgment of his services he was knighted by Charles I.; and he received a similar honour from Philip IV.

In 1630 Rubens married his second wife, Helena Fourment, a beautiful girl of sixteen; in 1635 he designed the decorations which celebrated the

entry of the Cardinal Infant Ferdinand into Antwerp as governor of the Netherlands; and, having with much difficulty completed a picture of 'The Crucifixion of St Peter' for the church dedicated to that saint in Cologne, he died at Antwerp on the 30th of May 1640, and was interred with great pomp in the church of St Jacques, his body being deposited, two years afterwards, in a chapel specially built there for its reception.

Not only was Rubens great as a subject-painter, but he was equally distinguished as a portraitist, an animal-painter, and a landscapist. The main characteristics of his productions are their power, spirit, and vivacity, their sense of energy, of exuberant life. As Reynolds has truly said, 'Rubens was perhaps the greatest master in the mechanical part of the art; the best workman with his tools that ever used a pencil; and he was great alike in handling and as a colourist. It is, however, mainly on technical grounds that he claims supremacy, for his works are wanting in the dignity, quietude, refinement, and in the profound imagination which distinguish the greatest Italian painters. He was a most prolific artist; his works number in all several thousands, of which Smith in his *Catalogue* has described over thirteen hundred; and about twelve hundred prints have been executed after his paintings and designs, frequently under his personal supervision by such of the best contemporary engravers as Pontius, Vosterman, Soutman, and the Bolswerts. Many of his finest works are still at Antwerp; but his art may probably be most adequately studied in the Pinakothek at Munich, which contains nearly a hundred examples of his brush, several of them ranking with his noblest efforts. Among the most distinguished of his many pupils were Van Dyck, Van Diepenbeck, Jordans, and Snyders.

See *Lettres Inédites de P. P. Rubens*, publiées par Emile Gachet (Brussels, 1840); *Life by De Waagen in Hauser's Hist. vresches Taschenbuch* (Berlin, 1833; trans. Noel, 1840); W. Noel Sainsbury, *Original Unpublished Papers Illustrative of the Life of Rubens* (1859); A. Michiels, *Rubens et l'École d'Anvers* (Paris, 1877); the volume by Kett (1880); that by Kuelens; the *Life by Michel* (trans. 1890); and books by Hope Koe (1906), Rosenberg (1905), Dillon (1909); Rooses and Kuelens, *Cotex. Diplomaticus Rubenianus* (1887 et seq.); and the monumental quarto of Max Rooses (1903; trans. 1904).

Rube'ola. See MEASLES.

Rübezahl. See RIESENBERGHE.

Rubiaceæ, a family of dicotyledonous plants, in which, according to many botanists, the Cinchonaceæ are included as a sub-family; but which, as restricted by others, consists entirely of herbaceous plants, with whorled leaves, angular stems, and numerous very small flowers; the calyx superior, with four, five, or six lobes, or almost wanting; the corolla wheel-shaped, or tubular, regular, inserted into the calyx, and with the same number of divisions as the calyx; the stamens equal in number with the lobes of the corolla; two styles; the fruit a dry pericarp with two cells, and one seed in each cell. The wider limits include well over 4000 species, chiefly tropical. To this family belong Madder (q.v.), Bedstraw (q.v.), and Woodruff (q.v.).

Rubianus. See CROTUS RUBIANUS.

Rubicon, a stream of Central Italy, falling into the Adriatic a little north of Ariminum, has obtained a proverbial celebrity from the well-known story of its passage by Cæsar, in the middle of January, 49 B.C. It formed the southern boundary of his province, so that by crossing it he virtually declared war against the Republic. Cæsar himself makes no mention of its passage; Suetonius, Plutarch, and Lucan tell how he hesitated awhile

on the bank and then crossed with the words, *Jacta est alea* ('the die is cast'). Hence the modern phrase 'crossing the Rubicon' is derived (with its applications to games of cards, &c.). A papal bull of 1756 identified the Rubicon with the modern Furo, but a comparison of distances shows that it must rather have been the Fiumicino or Rugone.

Rubidium (sym. Rb; atom. number, 37; atom. wt. 85.45) is one of the alkali metals. Its salts exist in very minute quantities in numerous mineral waters, and in these rubidium salts, along with cesium salts, were detected by Bunsen and Kirchhoff by means of spectrum analysis. The mineral lepidolite is the best material to prepare rubidium compounds from. The metal is, like cesium, silver-white. It melts at 38.5° C., but is still soft at -10° C. Its sp. gr. is 1.52. Like cesium, it takes fire spontaneously in the air, and it decomposes water at the ordinary temperature, in the latter respect resembling all the other alkali metals. The salts of rubidium resemble generally those of potassium. The name rubidium is derived from *rubidus*, 'dark red,' in allusion to the colour imparted to a flame by the salts of the metal.

Rubinstein, ANTON, pianist and composer, was born of Jewish parents near Jassy in Moldavia in 1829, and received an early education in music. Liszt heard him play as an infant prodigy in Paris in 1841, and recognised his genius at once. After some further touring and some serious study in Berlin and Vienna, Rubinstein taught music in St Petersburg from 1848 to 1854. From 1862 to 1867 he was the director of the conservatoire, of which he had been one of the founders, and in 1887 he was induced to resume the directorship. Otherwise his life was spent in brilliant concert tours all over Europe. He visited England in 1842 and in 1857, and had an enthusiastic reception in the United States in 1872. As a pianist he held the highest rank, with a supreme mastery of technique. Opinions differed about his fidelity to a composer's intentions, but his playing was always characterised by deep emotional feeling and powers of expression. Rubinstein was also a prolific composer, but few of his works have survived, except in the smaller forms. His works include several operas, of which *The Demon* and *The Maccabees* are the best, five symphonies, the 'Ocean' and the 'Dramatic' being the best known, various cantatas, concertos, songs, and pieces of chamber music. His style, influenced by Schubert and Mendelssohn, tends to be diffuse without being specially distinctive, and it is very unlikely that his works will ever again come into favour. He died in 1894.

His brother, NICHOLAS RUBINSTEIN (1835-81), also an excellent pianist, founded the conservatoire at Moscow.

See *Autobiography of Anton Rubinstein*, trans. from the Russian by Aline Delano (1891), and studies and biographies by M'Arthur (1889), Zabel (Leipzig, 1892), and Cuthbert Cronk (1900).

Ruble. See ROUBLE.

Rubrics (Lat. *rubrica*, from *ruber*, 'red'), in classic use, meant the titles or headings of chapters in law-books, and is derived from the red colour of the ink in which these titles were written, in order to distinguish them from the text. In mediæval and modern use the name is applied to the directions in the service-books of the church as to the ordering of the prayers and the performance of the ceremonies that accompany them. The first printed missals have few rubrics, and the printing of both the words and ceremonies of the mass in full dates only from 1485. The same name, together with the usage itself, is retained in the Book of Common Prayer; and in all cases, even where the direction has ceased to be printed in red ink, the name

rubric is still retained. Where red ink is not employed the rubric is distinguished from the text by italics or some other variety of print.

Rubruquis, WILLIAM DE, a mediæval traveller, was born, it is pretty certain, at Rubronck (8 miles N.E. of St Omer, in northern France), and not at Ruysbroeck, near Brussels, early in the 13th century. He entered the Franciscan order, and was sent by Louis IX. of France into central Asia for the purpose of opening up communications with Sartak, the son of the Mongol prince, Batü Khan, a supposed Christian. Friar William travelled (1253) by way of Constantinople across the Black Sea and the Crimea to the Volga. Sartak referred him to his father, Batü, and that prince sent him forward to the Mongol emperor, Mangü Khan, whom he found on 27th December, about 10 days' journey south of Karakorum in Mongolia. With that sovereign he remained until July 1254, then returned to the Volga, penetrated the defiles of the Caucasus, proceeded through Armenia, Persia, and Asia Minor, to Syria, and arrived at Tripoli in August 1255. King Louis had meanwhile returned to France, and Friar William wrote him the account of his journey which has come down to us. It has been called the greatest geographical masterpiece of the Middle Ages by virtue of its truthfulness and freedom from invented marvels. Of the later history of Rubruquis the only fact known is that he was living in 1293, when Marco Polo was returning from the East.

Rubus, a genus of plants of the family Rosaceæ, distinguished by a 5-lobed calyx without epicalyx, and the fruit formed by an aggregation of small drupes adhering to each other upon a long *torus*. The fruit is eatable in all, or almost all, the species. The genus is a large one, comprising some 300 species, widely distributed over nearly every part of the globe. Among the most important species are *R. Chamaemorus*, the Cloudberry (q.v.); *R. Idæus*, the Raspberry; *R. cæsius*, the Dewberry; *R. arcticus*, characterised by Linnaeus as the prince of wild berries; *R. fruticosus*, the Common Bramble (q.v.); and *R. saxatilis*, the Stone Bramble. Of the Common Bramble, a number of varieties having very large luscious fruit have been introduced into Britain from North America with the view of cultivating them for their fruit. They are much appreciated in Canada and in the United States. The Loganberry is a hybrid between Blackberry and Raspberry. The ornamental species frequently planted in British gardens are *R. odoratus*, the Virginian Raspberry; *R. laciniatus*, with large flowers and elegant leaves; and *R. biflorus*, whose snow-white bark contrasts strikingly with the dark-green leaves.

Ruby, a gem much prized, is a pure transparent, red-coloured Corundum (q.v.), just as Sapphire (q.v.) is a blue variety of the same mineral. It is inferior in hardness to the diamond only among gems. Although usually red, yet violet, pink, and purple rubies are met with, but the most highly esteemed are those which have the colour of pigeon's blood. The finest true oriental rubies are more highly prized than diamonds of similar size and quality; those over a carat in weight are worth on an average £30 per carat, and no stone increases so much in value in proportion to increase in size. But perfect specimens, as regards colour, transparency, and freedom from flaws, are much less common than good diamonds. Gems of this character seldom exceed 8 or 10 carats; but Gustavus III. of Sweden presented one to the Empress Catharine, which was of the size of a pigeon's egg. The throne of the Great Mogul, according to Tavernier, was adorned with 108 rubies of from 100 to 200 carats each. One possessed by the king of Ceylon was,

according to Marco Polo, a span in length, as thick as a man's arm, and without a flaw; Kublai Khan offered for it the value of a city, but the king would not part with it. The Burmese government sent two rubies to London in 1875, one of which, reduced by recutting to 32½ carats, was sold for £10,000; the other, of 38½ carats, was sold for £20,000. The specific gravity of the ruby (3·900 to 4·2833) exceeds that of all other gems. When rubbed it becomes electrical, and remains so for some time. The finest rubies—those having the colour of pigeon's blood—come from Upper Burma, near Mogok, north of Mandalay (see BURMA). Dark-red rubies, sometimes with a brownish tint, are found in Siam, and purplish rubies in Ceylon. Rubies are also met with in the mountain-region of Yunnan in China, in Afghanistan, and in the basin of the Oxus. The true or oriental ruby, as above described, occurs in crystalline limestone in Burma, and in alluvial deposits which have been derived from the denudation of granitoid igneous and schistose rocks. Ruby-bearing gravels and sands occur sparingly in Europe, as in Auvergne, Bohemia, the Urals, &c. Small rubies have also been detected in such rocks as basalt, as in Victoria and New South Wales; and fine rubies have been reported to be found in New Guinea. Many of the so-called rubies of jewellers are not true or oriental rubies, but varieties of Spinel (q.v.), a mineral composed chiefly of alumina and magnesia, inferior in hardness and of less specific gravity than the oriental ruby, and crystallising in the cubical system. Oriental rubies belong to the hexagonal system, and, unlike the spinel, are always dichroic. Spinel rubies are found in the form of crystals or rounded pebbles in alluvial deposits and in the beds of rivers in Ceylon, Siam, Pegu, Badakshan, and other eastern countries, having been derived like the true ruby from crystalline igneous and schistose rocks. They occur also in crystalline limestone and in serpentine. Small rounded spinel-rubies occur in the sands of mountain-streams in Wicklow; and large crystals have been found in various parts of North America, but rarely, if ever, fit for the purposes of the jeweller. Spinel rubies are also found in Australia. *Spinel-ruby* is the name given by jewellers to a stone of a deep cambrine-red; a rose-red stone is distinguished as *Bates ruby*; red with a decided tinge of orange is *Vermel* or *Vernicle*; yellow or orange-red is *Rubicelle*; violet is *Almandine ruby*. There are also transparent spinels, which when large and fine are treated as jewels. All these, however, are merely variously-tinted varieties of one and the same mineral—spinel—which is allied to Corundum (q.v.), being composed mainly of alumina, with a smaller proportion of magnesia.

Synthetic rubies are made from precipitated alumina by fusion in an inverted blowpipe flame, the characteristic colour being obtained by adding 2 to 3 per cent. of chromium alum to the ammonium alum from which the alumina is precipitated. The artificial rubies can be distinguished from natural stones, as a rule, by the presence of air-bubbles and curved streaks not found in the latter.

Rückert, FRIEDRICH, German poet, was born at Schweinfurt, 16th May 1788, and educated there and at Würzburg. For some years he led a wandering life, studying philology and poetry, and cultivating the muses. During this period of his life he helped Arndt and Theodor Körner to fan the flame of German patriotism by his *Deutsche Gedichte* (1814), especially by the *Geharnischte Sonette* included in this volume. From 1826 to 1841 he filled the chair of Oriental Languages at Erlangen; but the greater part of his summers were passed at the country seat of his wife's parents, Nenns near Coburg. After learning

Persian, Arabic, and Turkish, incited thereto by Hammer-Purgstall at Vienna (1818), Rückert recast in German verse, with great skill, several of the famous poems of the East, as *Die Verwandlungen des Abu Seid of Hariri* (1826), *Nal und Damajanti* from the *Mahābhārata* (1828), *Rostem und Sohrab* from Firdaus's *Shah-Namah* (1838), *Amrirkais* (1843), *Hamisa* (1846), a collection of Arabic folk-songs, and others. His most popular books are the collection of lyrics entitled *Liebesfrühtling* (1844) and the reflective poems gathered together as *Die Weisheit des Brahmanen* (1836-39). In 1841 Frederick-William IV. invited him to Berlin, making him professor of Oriental Languages; but the poet preferred his idyllic life at Neuses, and went back there in 1848. There he died on 31st January 1866. Rückert wrote with fatal ease; he tried nearly all forms of poetical composition, and produced too much. Nevertheless he penned several charming little lyrics, which may be read in the selected *Gedichte* (1841). Two qualities distinguish his work in general: a marvellous command of language and rhyme, and the gift of giving poetic expression to philosophic thought. The former sometimes led him into mannerisms of form and unpleasant *lours de force*; the latter often betrays him into throwing a poetic glamour over dull, pedantic, and unimportant ideas. His posthumously published work includes German adaptations of Theocritus, Aristophanes, Kālidāsa's *Sākuntala* (1867), *Sādi's Bostān* (1882), and a good deal of original poetry.

Rudbeckia, a North American genus of Composite, of the Sunflower sub-family.

Rudd. See RED-EYE.

Rudder. See STEERING.

Rudder-fish, a name loosely applied to at least three different kinds of fish, of which the Pilot-fish (q.v.) is one.

Ruddiman, THOMAS, Latin grammarian, was born near Banff in 1674, and in 1690 gained a bursary at King's College, Aberdeen, taking his M.A. four years later. In 1695 he became parish schoolmaster of Laurencekirk, and here in 1699 accidentally made the acquaintance of the celebrated physician and Latinist, Dr Archibald Pitcairne, who was so impressed with his learning and sagacity that he got him appointed assistant-keeper of the Advocates' Library, Edinburgh. His new office gave him ample opportunity for prosecuting his favourite studies, but the remuneration was so small (£8, 6s. 8d. *per annum*) that, in 1707, he started business as a book auctioneer. In that year he edited Florence Wilson's Latin *Dialogue on the Tranquillity of the Mind*, to which he prefixed a life of the author; in 1709 Arthur Johnston's *Poetical Paraphrase of the Song of Solomon and Cantica*, both also in Latin. In 1714 appeared his well-known *Rudiments of the Latin Tongue*: in 1715 his great edition of Buchanan's works. He now exchanged the calling of a book auctioneer for the more congenial one of printer; and in 1728 he was appointed printer to the university, in 1730 principal keeper of the Advocates' Library. In 1725-32 he published his great *Grammaticæ Latinæ Institutiones*, on which his philological reputation mainly rests; in 1739 he completed Anderson's magnificent *Diplomata et Numismata Scotticæ*, writing the learned Latin introduction and appendices. Controversy as to the respective merit of the Latin verse of Johnston and Buchanan, and as to the hereditary right of the kings of Scotland to the crown, consumed a great part of his time, but did not so preoccupy his thoughts as to prevent him from publishing in 1751 an edition of Livy, still known as the 'immaculate,' from its entire exemption from errors of the press.

Ruddiman died in Edinburgh 19th January 1757. He was in politics, like his friend Pitcairne, an ardent Jacobite, and in private life a most upright and estimable man. Besides the publications already noted, and much else, he edited Gavin Douglas's translation of the *Æneid* (folio, 1710), and appended a very valuable glossary which became the basis of Jameson's Dictionary and so of Scottish lexicography. He also founded the *Caledonian Mercury* newspaper. See his Life by George Chalmers (1794).

Rüdesheim, a town of Prussia, on the right bank of the Rhine, opposite Bingen, at the foot of the Niederwald (q.v.), and 16 miles W. of Mainz. Round Rüdesheim is grown one of the most esteemed of the Rhine-wines, the Rüdesheimer.

Rudolf, or RUDOLPH, German king and founder of the late imperial dynasty of Austria, was born in Limburg castle in the Breisgau, on 1st May 1218. He became a warm partisan of Frederick II., distinguished himself in arms, and spent much of the early years of his manhood in quarrels with the bishops of Basel and Strasburg. His possessions were greatly increased by inheritance and by his marriage, until he was the most powerful prince in Swabia. In 1273 the electors chose him to be German king; as never having been crowned by the pope, he was not entitled to be called kaiser or emperor. His accession was opposed by none; the pope's consent was secured at the price of certain rights already parted with by Rudolf's predecessors. Ottocar of Bohemia, however, refused to tender his allegiance. He was put under the ban of the empire in 1276, but, submitting on Rudolf's approach with an army, was invested with Bohemia. Having soon afterwards taken the field against his suzerain, he was defeated and slain in 1278 on the Marchfeld beside the Danube. Rudolf spent the greater part of his life that remained in suppressing the castles of the robber knights and putting an end to their lawless practices. He died at Spiers, 15th July 1291, and was buried in the cathedral there. His son Albert, to whom (and his brother Rudolf) Austria, Styria, and Carniola had been given in 1278, succeeded him as German king. Rudolf was a pattern knight, tall in person, upright, pious, valiant, and energetic. See Lives by Schönbrunn (1844), Kopp (1845), and Hirn (1874); Lorenz, *Deutsche Geschichte in 13. und 14. Jahrhundert* (1863-67); and a work by Kaltenbrunner (Prague, 1890).

Rudolf II., eldest son of the Emperor Maximilian II., was born at Vienna on 18th July 1552, and educated at the Spanish court by the Jesuits. He was made king of Hungary in 1572, king of Bohemia, with the title King of the Romans, in 1575, and on the death of his father in 1576 succeeded to the imperial crown. Gloomy, taciturn, bigoted, indolent both in body and mind, he put himself in the hands of the Jesuits and low favourites, and left the empire to govern itself. His attention was given to his curiosities, his stable, his alchemical and magical studies; nevertheless his taste for astrology and the occult sciences, and his desire to discover the philosopher's stone, made him extend his patronage to Kepler and Tycho Brahe. The astronomical calculations begun by Tycho, and continued by Kepler, known as *The Rudolphine Tables*, derive their name from this emperor. Meanwhile the Protestants were bitterly persecuted by the Jesuits throughout the empire; the Turks invaded Hungary and defeated the archduke Maximilian (1596); Transylvania and Hungary rose in revolt; and at last Rudolf's brother Matthias wrested from him the crowns of Hungary and Bohemia, and the states of Austria

and Moravia. Less than a year after losing the crown of Bohemia he died, unmarried, on 20th January 1612, and was succeeded by Matthias. See works by Gindely (1865) and Von Bezold (1885).

Rudolf, LAKE, a lake in Kenya, Sudan, and Abyssinia, near the edge of the Kaffa or South Ethiopian highlands, is long and narrow, stretching 160 miles N.E. and S.W. by 40 broad, with an area of 3000 sq. m., at a height of 1300 feet above the sea. It is crossed by 4° N. lat. and 35° E. long. It has no visible outlet, and its waters are very brackish. It was discovered by L. von Höhnel and Count Teleki in 1888. See von Höhnel's *Discovery of Lakes Rudolf and Stephanie* (Eng. trans. 1894).

Rudolstadt, a town of Thuringia, lies in a hill-girt valley, on the left bank of the Saale, 18 miles S. of Weimar. There are two castles, a library, picture-gallery, &c., and factories for porcelain, chemicals, and wool. Pop. 16,000.

Rudra is, in Vedic mythology, a collective name of the gods of the tempest, or Maruts. In later and Puranic mythology Rudra ('the terrible') is a name of Siva, and the Rudras are his offspring.

Rue (*Ruta*), a genus of Rutaceæ, half-shrubby plants, natives of the south of Europe, the north of Africa, the Canary Isles, and the temperate parts of Asia. Common Rue, or Garden Rue (*R. graveolens*), grows in sunny stony places in the countries near the Mediterranean. It has greenish-yellow flowers, the first of which that open have ten stamens, the others eight only (they are of unequal length, and each one is bent inwards in turn to touch the pistil, and when the pollen is shed it bends back again), and glaucous evergreen leaves with small oblong leaflets, the terminal leaflets obovate. It is not a native of Britain, but is frequently cultivated in gardens. It was formerly called *Herb of Grace* (see *Hamlet*, act iv. scene 5), because it was used for sprinkling the people with

Common Rue (*Ruta graveolens*).

holy water. It was in great repute among the ancients, having been hung about the neck as an amulet against witchcraft in the time of Aristotle. The smell of fresh rue is very offensive to many. — *Meadow rue* (*Thalictrum*) belongs to the Ranunculaceæ.

Ruff (*Machætes pugnax*), a bird, the sole representative of the genus, belonging to the Sandpiper (q.v.) sub-family of the Snipe family (Scolopacidae). In the British Isles it is now little more

than a visitor in its spring and autumn migrations, owing to the draining of its marshy breeding-places and the practice of capturing it in spring when game is out of season. It is more common on the east than on the west coast of England. The same is true of the east coast of Scotland, where it is found from Berwick to the Orkneys and Shetlands, but it has been recorded from the Outer Hebrides. As a straggler it is found on the Faroes and Iceland, in Canada, in some of the eastern United States, and it has been found once in Barbadoes and once on the Upper Orinoco. It breeds over the greater part of northern Europe; it is found as a migrant over the rest of Europe, the southern shores of the Mediterranean, and the east and west coasts of Africa as far as the Cape; in Asia it extends from Siberia to Japan, Burma, and India. The male bird, the *Ruff*, is about a foot long. In spring it sheds the feathers of the face; curled tufts of feathers appear on the sides of the head; and an erectile ruff is developed which lasts for a couple of months. This ruff, as well as the feathers on the back, shows every variation of colour in different birds; but each bird annually regains its own peculiar colour. After moulting the neck and upper breast are of a buff colour; the under parts dull white; the feathers of the upper parts are dark brown with buff margins; and the primary wing-feathers are dusky brown. The female, the *Reeve*, is about one-fourth smaller in size, and shows very much the same colours as the mottled male. In habit these birds are polygamous; the males fight for possession of the females, and in battle the ruff serves for defence. The nest is made among the coarse grass of a dry tussock in a moist swampy place. The eggs, four in number,

Ruff (*Machætes pugnax*).

are grayish green marked with reddish brown. The food consists of insects and their larvae, worms, seeds, rice, and other vegetable substances. When captured and being fattened for the table, the birds are fed on boiled wheat, bread and milk, and bruised hemp-seed.

Ruffe, or POPE (*Acerina cernua*), a small freshwater fish of the Perch family (Percidae), abundant in the lakes, slow rivers, and ditches of many parts of the middle of Europe and of England. It is five or six inches in length, of an olive-green colour mottled with brown, and has only one dorsal fin. The flesh of the ruffe—also spelt ruff—is highly esteemed for the table.

Rufiji, or RUFJI, a river of Tanganyika Territory, which rising far in the interior enters the sea through a delta opposite the island of Mafia. Shoals and bars at the month prevent the access of large ships; but the river is navigable by smaller

boats throughout great part of its course. The valley is extremely fertile.

Rugby, a town in Warwickshire, near the river Avon, 82 miles NW. of London, 12 miles E. of Coventry, is an important junction of the L.M.S. Railway. Although known in Doomsday as Rocheberie (later Rokeby), most of the town is modern, and it is chiefly known by its famous school. In March 1645 the town was occupied by Oliver Cromwell. In 1923 a government wireless station was erected here to provide a means of radio communication throughout the British empire. The high-frequency valve generators have a maximum output of 500 amperes, into an aerial supported on 12 masts, each 820 feet in height. The industries are principally concerned with electrical engineering; there is a large cattle market. It is a well-known hunting centre. Pop. of urban district (1901) 16,830; (1911) 21,758; (1921) 25,088.

The school was founded in 1567 by Lawrence Sheriff, a native, who made a fortune as a grocer and dealer in spices, but the original buildings have long since disappeared. Mainly fed at first by boys from the midlands, its reputation gradually increased under such men as Dr Henry Holyoake and Dr Thomas James, but its national fame came under Dr Thomas Arnold, who, in raising the school, raised the dignity of his whole profession. After Arnold came successively Archibald Campbell Tait (1842-50), afterwards Archbishop of Canterbury; Dean Goulburn (1850-58); Dr Temple (1858-69), afterwards Archbishop of Canterbury; Dr T. W. Jex-Blake (1874-87); Dr John Percival (1887-95), afterwards Bishop of Hereford; Dr H. A. James; Dr David, afterwards Bishop of Liverpool; and W. W. Vaughan (1921). From Rugby went the first head-master to Marlborough, Wellington, Clifton, Haileybury, and other schools. Illustrious Rugbyans include Dean Stanley, who wrote the biography of his famous head-master; Thomas Hughes, who immortalised the school in his *Tom Brown's School-days*; Dean Vaughan; Dr Samuel Butler; 15th Earl of Derby; Viscounts Cross and Goschen; Lord Davey (Lord of Appeal); Rondell Palmer (Lord Chancellor); Sir Richard Temple; Judge Bowen; Professor Henry Sidgwick; Judge Farwell; Walter Savage Landor; Arthur Henry Clough, the poet; Matthew Arnold; H. W. Fox, a missionary to India, to whose memory a fund was raised to support one Indian missionary (a 'Fox Semion' is preached annually); Sir Henry Wilmot, V.C.; W. C. Macready, the actor; M. H. Bloxam, author of *Gothic Architecture*, who left his collections of antiquities and books to the school; Charles Appleby (better known as 'Nimrod'); C. L. Dodgson, the author of *Alice's Adventures in Wonderland*; F. C. Selous, the hunter; H. O. Arnold-Forster, Dr Arnold's grandson; Rupert Brooke, poet; Sir Austen Chamberlain; Sir Charles Nicholson, Bt., architect; P. F. Warner, the famous cricketer; Baron Stuart of Wortley; Baron Killbracken; Sir E. Maunde Thompson; and Judge Tobin. The Memorial Chapel, completed in 1923 to designs by Sir C. Nicholson, is to the memory of 682 old boys who fell in the Great War (1914-18), whose names are inscribed on the walls. More than £50,000 was raised for this memorial and for a fund to provide for the education of the sons of the fallen Rugbyans. Rugby football (see FOOTBALL) was originated here in 1823 by William Webb Ellis.

See, besides Stanley's *Life of Arnold* and Hughes's *Tom Brown's School-days*, *Rugby School Registers, 1675-1904* (3 vols.); Bloxam and Smith's *Rugby: its School and Neighbourhood* (1889); W. H. D. Rouse's *History of Rugby School* (1898), which has a full bibliography; Bradley's *Rugby* (1900); W. Eadon's *Guide to Rugby School* (pamphlet, 1923); and W. N. Wilson's *Rugby School Memorial Chapel* (1923).

Rugby, TENNESSEE. See HUGHES (THOMAS).

Rugeley, a market-town of Staffordshire, on the Trent, 10 miles ESE. of Stafford. It has good public buildings (1879), a grammar-school, iron-works, and neighbouring collieries. Pop. 4600.

Rügen, an island of Prussia, lies in the Baltic, off the coast of Hither Pomerania. Greatest length, 33 miles; greatest breadth, 25 miles; area, 374 sq. m. It is separated from the mainland by a strait about a mile in width. The island, which is deeply indented by the sea, terminates at the north-eastern extremity in the precipitous cliff called the *Stubbenkammer* (400 feet). Erratic boulders are common all over the island. Numerous barrows exist. Heitha Lake was once believed to be the place where, according to Tacitus, the Germanic goddess Nerthus was worshipped. The soil is productive, and yields good wheat; cattle are reared; and fishing is carried on. The scenery, everywhere pleasing, is frequently romantic, and, together with the facilities for sea-bathing, attracts numerous visitors. Chief town, Beign, in the middle of the island. Rügen was occupied originally by Germanic tribes, then by Slavs, was conquered by the Danes in 1168, was thereafter ruled by native princes under Danish suzerainty, passed to a branch of the ruling family of Pomerania in 1325, in 1478 was incorporated with Pomerania (q.v.), and shared its destinies.

Ruhmkorff, HEINRICH DANIEL, electrician, born at Hanover in 1803, in 1839 settled in Paris, and died there 21st December 1877. His Induction Coil, exhibited in 1855, is described and figured at INDUCTION.

Ruhnkens, DAVID, classical philologist, was born 2d January 1723 at Stolpe, in Pomerania, received his education at Königsberg, at Wittenberg University, and at Leyden under Hemsterhuis, who taught him Greek. Ruhnkens's first works were to prepare a new edition of Plato, to collect the scholia on that author, and publish an edition of Timæus's *Lectiones Vocum Platoniarum* (Leyden, 1754: a much improved edition, 1789). In 1755 he went to Paris, and spent a whole year there examining the MSS. of the Royal Library and of the Library of St Germain. Hemsterhuis then got him appointed assistant to himself (1757) at Leyden. In 1761 he succeeded Oudendorp in the chair of Eloquence and History. In 1774 he succeeded Gronovius as librarian to the university, which he enriched with a multitude of valuable books and MSS. He died 14th May 1798. One of the best scholars and critics of the 18th century. Ruhnkens possessed fine taste and sagacity, vast learning, and a remarkably lucid and graceful Latin style. His principal literary works embraced *Epistolæ Criticæ* (1749-51), an edition of Rutilius Lupus (1768), of Velleius Paterculus (1779), of Muretus (1789), &c. His pupil Wytenbach wrote his *Life* (Leyden, 1799).

Ruhr, a right-hand affluent of the Rhine, rises in Westphalia, near the south-west frontier of Waldeck, flows generally west, and, after a course of 144 miles, joins the Rhine at Ruhrort. The Ruhr basin, a very important mining and manufacturing district, played an important part in the revolution. In accordance with M. Poincaré's policy of putting pressure upon Germany, a great part of it was occupied by French and Belgians in 1923-25.

Ruhrort, a great Rhine port, at the influx of the Ruhr, is now part of Duisburg (q.v.).

Ruisdael. See RUYSDAEL.

Rule, ST. See REGULUS.

Rule of Faith, not the sum of the Christian faith as laid down in Creeds (q.v.) and Confessions

(q.v.); but, in polemical theology, the sources whence the doctrines of the faith are to be authoritatively derived—the Scriptures, the tradition of the Church, the teaching of the fathers, &c. See ROMAN CATHOLIC CHURCH, REFORMATION, CHILLINGWORTH, NEWMAN, &c.

Rule of the Road. This phrase includes the regulations to be observed in the movements of conveyances either on land or at sea. *On Land:* In Britain drivers, riders, and cyclists keep the side of the road next their left hand when meeting, and that next their right when overtaking and passing other horses or vehicles. The person neglecting this rule is liable for any damage that may happen through such neglect. A man riding against a horse, or a conveyance driving against another that is standing still, is answerable for any damage that may ensue. On the Continent and in America drivers and riders keep to the right. *At Sea:* If two steamers are meeting end on or nearly end on, both alter their courses to starboard—i.e. both turn to their right hand. If two steamers are crossing each other, the one which has the other on the starboard (right hand) side keeps out of the way. A steamer must keep out of the way of a sailing ship. A steamer shall slacken speed or stop and reverse if necessary. If two sailing ships are approaching each other, whether meeting or crossing, one running free keeps out of the way of one close-hauled; one close-hauled on the port tack keeps out of the way of one close-hauled on the starboard tack; one with the wind free on the port side keeps out of the way of one with the wind free on the starboard side; where both have the wind free on the same side the one to windward keeps out of the way of the one to leeward; and a ship with the wind aft keeps out of the way of the other ship. Notwithstanding the above rules, a ship, whether a sailing ship or steamship, overtaking any other must keep out of the way of the overtaken ship. Where one ship is to keep out of the way, the other must keep her course. Regard, however, is to be paid to all dangers of navigation, and to any special circumstances which may render a departure from the rules necessary to avoid immediate danger. For lights, see **SIGNALLING**.

Rullion Green. See **PENTLAND HILLS**.

Rum, a mountainous island of Inverness-shire, belonging to the group of the Inner Hebrides, 15 miles N. by W. of Aidnamurchan Point. It is 8½ miles long, 8 miles broad, and 42 sq. m. in area, only 300 acres being arable, and the rest deer-forest and moorland. The surface presents a mass of high sharp-peaked mountains, rising in Halival and Haiskeval to the height of 2368 and 2659 feet.

Rum, a kind of spirit made by fermenting and distilling the 'sweets' that accrue in making sugar from cane-juice. The summings from the sugar-cans give the best rum that any particular plantation can produce; summings and molasses the next quality; and molasses the lowest. Before fermentation water is added, till the 'sett' or wort is of the strength of about 12 per cent. of sugar; and every ten gallons yields one gallon of rum, or rather more. The flavour of rum depends mainly on soil and climate, and is not good where canes grow rankly. Pine-apples and guavas are at times thrown into the still, but on the great scale no attempt is made to influence flavour artificially. The finest flavoured rums are produced by the old-fashioned small stills. The modern stills, which produce a strong spirit at one operation, are unfavourable to flavour. The colour of rum is imparted after distillation by adding caramel.

RUM SHRUB, a liquor in which the alcoholic base is rum, and the other materials are sugar,

lime or lemon juice, and the rind of these fruits added to give flavour.

Rumania (*România*), a kingdom in the south-east of Europe, situated between 20° and 30° E. long. and 43½° and 48½° N. lat. Its general boundaries are on the east the river Dniester and the Black Sea, on the south the river Danube (except for the Dobrudja, a province on the extreme south-east), but on the north and west natural physical boundaries have given way to an ill-defined line extending from Hotin on the Dniester west to Mako (the meeting-place of Rumania, Hungary, and Yugo-Slavia) and then south to Bazias on the Danube. The kingdom is compact, the frontier being 1783 miles in length. As a result of the Great War the area of Rumania was more than doubled (see *History*).

Country.	Area, square miles.	Estimated Population.	Chief Town.
Wallachia	29,960	5,226,000	Bucharest
Moldavia	14,710	2,337,000	Jassy.
Dobrudja	8,819	722,000	Constanza.
Bessarabia	17,146	2,957,000	Chisinau.
Bukovina	4,030	820,000	Cernauti.
Transylvania	22,312	2,860,000	Cluj.
Crisana	8,038	1,158,000	Oradea Mare.
Maramuresh	6,258	520,000	Sighetula.
Banat	11,000	950,000	Temesovar.
	122,282	17,500,000	

Of this total population about 13,200,000 are Rumanians, 1½ million are Magyars, a million are Jews, three-quarters of a million are Germans (Saxons), and the remainder are mostly Russians, Ruthenians, Bulgarians, and Turks, while there are also a considerable number of Gypsies. At the end of the 19th century there were about 5½ million Rumanians in the old kingdom, with some 4½ million living in the adjoining countries. The capital and seat of government is Bucharest (Rum. *Bucuresti*) with some 600,000 inhabitants. Other towns are Chisinau (Russ. *Kishinev*, 200,000), Cluj (Germ. *Klausenburg*, 105,000), Czernowitz (Rum. *Cernauti*, 90,000), Temesovar (90,000), Oradea Mare (90,000), Jassy (Rum. *Iasi*, 76,000), Galatz (Rum. *Galati*, 75,000), and Arad (75,000). Curtea d'Argesh, the medieval capital of Wallachia, now a village, is famous for its 13th century cathedral, built of a grayish-white limestone resembling alabaster, in the Byzantine order of architecture, with a profusion of Moorish or Arabesque ornamentation. Simau, on the river Prahova on the lower slopes of the Carpathians, is the fashionable summer resort for the court and society.

There are separate articles on the BANAT, BESSARABIA, BUKOVINA, DOBRUDJA, TRANSYLVANIA, &c.

Physical Aspects.—In the south and east the Wallachian plain extends into Bessarabia and the Dobrudja (Rum. *Dobruja*), and continues into the Ukraine. The main chain of the Carpathians, entering the centre of the kingdom

the north, eventually curves west, encircling the Transylvanian plateau. The Carpathians are characterised by no outstanding peaks, but rather by rolling uplands, hardly any of the hills exceeding 8000 feet. Rumania is plentifully supplied with rivers, those on the north-west of the Carpathian water-shed, including the Maros, flowing mostly into the Theiss (Rum. *Tisa*), and those on the south-east, including the Pruth and the Oltu, direct into the Danube. The Dniester and the Danube both act as frontiers for part of their courses, but the embouchures of the latter are wholly in Rumanian territory. There are three

zones of country: the Carpathians, which are covered with forests and rich mountain pasture, and have an annual rainfall of over 35 inches; the hill-region, consisting of the Transylvanian slopes and the western part of Moldavia, well adapted for every kind of agricultural industry; and the Southern Steppes, hot and arid, with an annual rainfall of less than 15 inches. The Balta region round about the mouths of the Danube is, however, extremely marshy, being flooded to the extent of some 2 million acres for five months every summer. Here there is a profusion of wild-duck and other marsh fowl, with otters, beavers, hedge-hogs, &c., and various brightly-coloured butterflies and other insects. In the higher lands stags, bears, wild boars, wolves, grouse, eagles are numerous, but the chamois is rare. The sylvan scenery of the Carpathians is very lovely, and either there or in the plains are to be found the oak, elm, beech, and less frequently the maple, sycamore, mountain-ash, lime, horse-chestnut, and acacia.

Occupations.—About four-fifths of the total population are peasants engaged in agricultural pursuits, the system of peasant proprietary being very remarkable. Before 1865 the whole of the land of the country was practically held by the boyars or inferior nobles (who were frequently absentees), or by the state, the peasants merely owning small patches of land contiguous to their huts, which were, and in some cases still are, semi-subterranean. The peasantry had been robbed of their land during long ages of feudal oppression and foreign conquest, but when the government became democratic it was determined to restore a portion of the land (about one-third) to its original owners at very moderate prices to be fixed by the state. Under Prince Conza the process began about 1865, the government advancing the purchase-money and creating a loan for the purpose. The greater portion of the debt was paid off by the peasant proprietors by 1881, but large ownership still preponderated. Nearly one-half of the whole country remained in the hands of little over five thousand owners, while many of the peasant holdings were too small to admit of the most advantageous and economical farming. The second restoration process began in 1918, when all lands (except forests, vineyards, and orchards) that were inalienable or that belonged to foreigners, absentees, corporations, institutions, and to the crown were expropriated. Further, private owners were called upon to supply between them 5 million acres of cultivated land, according to a sliding scale, which left no former owner with more than 1250 acres or with less than 250 acres. Altogether about 7 million acres changed hands, the peasant being given a minimum of 12½ acres. In compensation the landlords were given 5 per cent. bonds, amounting to 50 per cent. of the value of the holding in 1914. Eventually the government took over 35 per cent. of the debt, leaving the remainder to be payable by the peasants in fifty years' time. Owing to various economic causes, chiefly the enormous depreciation of the currency, this valuation has been very unfair on many landlords. Now the peasants possess 85 per cent. of the whole area, one of the highest proportions existing in any country.

Production and Industry.—The industries of Rumania suffered severely on account of the Great War. The German occupation, the threat of Bolshevism (which delayed the demobilisation of the army), the disorganisation of the railways, all the changes of the Agrarians Reforms, the great expense (for the peasants) of agricultural machinery, and the lack of capital have all hindered the proper development of the exceptionally rich agricultural and mineral resources. The chief agricultural crops

—maize, wheat, oats, and barley—are cultivated over an area of some 24 million acres, the total harvest averaging 10 million metric tons, of which one-half is maize and one-quarter wheat. Normally, after the United States of America and Russia, Rumania is the greatest grain-producing country in the world. Tobacco is grown extensively, and there are about 600,000 acres of vineyards, besides orchards of plums, peaches, apples, pears, &c. The best agricultural districts are found in Wallachia, Moldavia, and Bessarabia, while there is excellent pasture for cattle, sheep, goats, and pigs in Transylvania. Horse-breeding is also important. The forests in Greater Rumania cover some 17 million acres, and the total water-power resources have been estimated at 1½ million h.p., but the timber trade so far has not been very extensive, and only a very small proportion of the hydraulic resources has been exploited at all.

The chief mining industry is that of petroleum, the production of which has increased from 250,000 metric tons in 1900 to 1,783,000 in 1914 and 2,313,000 in 1925, most of the petroleum wells being in the region round Ploësti in Wallachia. Lignite is produced to the extent of 2½ million tons annually, and there are salt-mines near Ocna in Moldavia, with an annual output of ½ million tons. Transylvania is said to possess the richest gold-mines in Europe, and other minerals, including iron and copper, are present in the soil. All mines (except stone quarries), springs, and natural sources of energy, such as water-power, are now under the control of the state (see *History*), but a vast amount of capital is required for their development.

Manufactures include breweries, paper-mills and wool-factories, while the state subsidises the petroleum-refineries, sugar-factories, and the flour and saw mills. The fisheries, especially of carp and sturgeon, are of considerable importance.

Commerce.—For the years immediately preceding the Great War, the imports averaged annually 22 million sterling in value, and the exports 26 million sterling, but after the war this standard was only regained in 1924, in spite of the annexation of so much territory. The chief imports are now cotton manufactures (about ⅓ of the total), metal and woollen manufactures and machinery; the chief exports are cereals and flour (about ⅓ of the total), mineral oils, wood manufactures, livestock and vegetables. Most of the trade is done with the countries of central Europe. Rumanian exports to Great Britain average annually 2½ million sterling in value (mainly for barley, maize, and petroleum) and the imports from Great Britain 4 million sterling (mainly for cotton piece goods, and iron, wrought and unwrought).

The principal ports are Brăila, Galatz, and Constantza (Rum. *Constanța*), but petroleum is also exported from Giurgiu on the Danube. Rumania is represented on the International Danube Navigation Commission (see DANUBE), which has its seat at Galatz. The total railway mileage amounts to 7246 miles, of which 2707 are in the Old Kingdom, but several projects of new lines, chiefly in Transylvania are under consideration, as the war made imperative a thorough reorganisation of the whole railway system.

Defence.—Military service is compulsory for all Rumanians from the ages of 21 to 50. The term of service for the infantry is two years in the active army and eighteen years in the regular army reserve, and for other ranks three and seventeen years respectively. Thereafter, all pass into the militia for nine years. The peace footing of the army, divided into seven army corps, is 11,400 officers and 135,000 other ranks. There is a small fleet stationed in the Black Sea.

Religion and Education.—Freedom of worship is supposed to be assured to all sects, but persecution of Unitarians, Baptists, and others has nevertheless continued; the state religion is that of the Orthodox Church. In 1925 a Patriarchate of Rumania was created, and there are other four archbishops and a number of bishops. There are also an archbishop and three bishops of the Greek Catholic Church, and Roman Catholic, Lutheran, Reformed, and Unitarian bishops. Of the total population, there are about 10 million belonging to the Orthodox Church, 1½ million Greek Catholics, 1½ million Roman Catholics, 1½ million Protestants, 800,000 Jews, as well as Mohammedans and others.

Education is free and compulsory 'wherever there are schools,' but about half the population over seven years of age can neither read nor write. Rumania has four universities, at Bucharest (1864), at Jassy (1860), at Cluj or Klausenburg (1919), and at Cernăuți (1920).

Constitution.—The revised constitution of 1923 allows for a king, who nominates the ministers, and has the right of vetoing the legislation proposed by the two chambers of Parliament. The Senate or Upper House is for the most part elective, but there are a few life members chosen for merit and position. Senators must be over forty years of age and deputies over twenty-five. The term of office is five years, all male Rumanian tax-payers over twenty-one having the franchise.

History and Political Relations.—The early Greek historians mention a Thracian tribe, the Getae, from whom were descended the Dacians, a brave race who occupied the northern side of the Ister or Danube, and flourished as a free people down to about the end of the first century of our era. Before that time the Dacians had come into conflict with both Greeks and Romans, but in the year 101 A.D. the Emperor Trajan undertook the first of two expeditions against their king, Decebalus, which terminated in the complete subjugation of the country. Historians are now generally agreed that the modern Rumanians are descended from the Roman colonists established by Trajan for the defence of this frontier. Pressed by the barbarian races who eventually compassed the downfall of the Roman empire, Dacia was evacuated by the Romans in the reign of Aurelian (about 274 A.D.), and for about a thousand years the banks of the Danube served as halting places for various wandering tribes, amongst whom the most conspicuous were the Goths; the Huns under Attila; the Lombards under Alboin; the Bulgari, who afterwards settled on the plains south of the Danube and founded Bulgaria; the Ungri, a savage race who settled in Hungary; and the Wallachs, from whom Wallachia has derived its name. For a considerable period both banks of the Danube formed part of the powerful Slavonic-Bulgarian state, which, however, was crushed by the Byzantine Empire in 1018, after Hungary had already conquered Transylvania. Later the Rumanians of the south formed an independent state, finally overwhelmed by a Tatar invasion about the year 1250 A.D. After that there gradually arose out of a number of smaller states an independent realm in Wallachia, with its traditions of heroes and chiefs, Mirecea the Old, Michael the Brave (d. 1601), whose memory is perpetuated by a beautiful equestrian statue at Bucharest, and others; whilst the neighbouring state of Moldavia had also its heroes in Stephen the Great (d. 1504), &c. These rulers for a long time resisted the Musulman advance, but were eventually reduced to vassalage by the victorious Turks, and were compelled to sign what are known as the 'Capitulations,' and to pay an annual tribute to the sultan. The first treaty with Wallachia

known by that name was signed as far back as 1393; but that with Moldavia, which country was supported by the king of Poland, followed as late as 1513.

Although Wallachia and Moldavia thus became states tributary to the Porte, they retained sufficient independence to be in a sense autonomous; but in the course of time their princes, or voivodes as they were called, where Turkish nominees, whose tenure of office may be judged by the fact that in the course of ninety years (from 1723 to 1812) the government of Wallachia passed through the hands of no less than forty of those rulers. They were mostly Greeks, known as Phanariotes or Fanariots (q.v.), who during their brief tenure of power practised the most scandalous extortions upon the people in order to enrich themselves and remit the annual tribute to Constantinople. The great majority of those Fanariot voivodes either were assassinated or were disgraced through the intrigues of their rivals at the Sublime Porte; and some of them did not scruple to appeal during their brief tenure of power for the support of Russia, which country was constantly at war with their suzerain.

The Muscovites began to make inroads into the Danubian principalities as early as the year 1769, under Peter the Great, and continued to invade them at intervals, especially in the reign of the Empress Anne in 1755 and in that of Catharine IV. in 1768. In the first instance the Tsar Peter was invited to enter the states by the voivodes Brancovano of Wallachia and Cantemir of Moldavia, who desired to secure their independence under his protection; but no such inducement was afterwards requisite; and although the Russian invasions and occupations were always undertaken on the pretext of liberating the Christians from the Musulman yoke, the real object has been to advance step by step to Constantinople and to secure possession of the whole Balkan peninsula. At different times the Russians exercised absolute sway in the principalities, notably from 1789 to 1792 and from 1806 to 1812, when the princes under their protection were called Hospodars (q.v.), a Slavonic word. In 1848 they helped to suppress the national rising there, as they did in Hungary, but in 1853, before the Crimean war, their power began to wane. At the termination of that war they were compelled by the allied powers to cede Bessarabia to the principalities.

In the year 1858 both principalities, united under the name of Rumania, elected Prince Conza (born at Galatz, 1820), under whose rule the important Agrarian Reforms of 1865 (see *Occupations*) were carried out, but in 1866 he was deposed on account of extortions and gross immorality, and was succeeded by Prince Charles of Hohenzollern. This revolution was mainly led by two able statesmen, Bratiano and Rosetti, who may be said to have been jointly the counterpart of the Italian Cavour, and who for many years enjoyed great popularity as the chief ministers of state. On the outbreak of the Russo-Turkish war in 1877 the Rumanians espoused the Russian cause. Prince Charles was actually appointed commander-in-chief of the allied armies, the Russian Cossack serving under him, and the Rumanians helped very materially to bring the war to a triumphant close. The conquerors, however, deprived their allies of part of their territory, Bessarabia, giving them in exchange the Dobrudja, which they exacted from the Porte—an exchange subsequently confirmed by the Berlin Conference (June 1878), when Rumania was recognised as a completely independent power. The effect of that exchange was, however, unfortunate for Russia in two respects. It caused a permanent estrangement between the Rumanians and their guardian allies, and the Dobrudja served

as a barrier against Russian aggression in Bulgaria. Indeed, throughout her history, Rumania has acted as a buffer state between Austrian and Russian interests in the Balkans. In 1881 Prince Charles, whose qualities as a statesman and soldier were invaluable in organising the country, was invested with the kingly dignity with the acquiescence of the European Powers.

A financial crisis 1899-1901, caused by undue extravagance, was surmounted with foreign loans, chiefly from Germany, and after the disturbances among the peasants in 1907, the government granted them fresh facilities for obtaining credit. Rumania took no part in the first Balkan war (1912), but declared war on Bulgaria the next year, and after a bloodless campaign annexed part of the Dobruja. The accession in October 1914 of King Ferdinand, Italy's declaration of war in 1915, and the victorious Russian offensives in Galicia led Rumania to enter the Great War on the side of the Allies in August 1916, but by December both the petroleum region and the capital Bucharest were occupied by the Central Powers. A second Rumanian offensive in 1917 met with inevitable failure after the collapse of Russia, and an armistice was concluded in December, but in April, November, and December 1918 respectively, Bessarabia, Bukovina, and Transylvania, were annexed, and the ancient empire of Michael the Brave was revived. A Bolshevik invasion of Rumania in 1919, organised by Bela Kun (see KUN), ended in the Rumanians occupying Budapest, and in 1922 the 'Little Entente' was concluded between Rumania, Yugoslavia, and Czechoslovakia. Since the war legislation has chiefly concerned itself with agrarian reforms (see *Occupations* above), with the unification of the new kingdom, and with the promoting of state control of certain industries, including the mines. The financial policy of the brothers Brătianu, though designed to prevent the foreign exploitation of the national resources, has rather discouraged the inflow of foreign capital that is so sorely needed for the country to recover from the effects of the Great War.

Language and Literature.—Rumanian (or Walachian) is one of the Romance Languages (q.v.), a daughter of the Latin; but, though the language is unmistakably Romance in type and in grammatical construction, the vocabulary is mixed, the number of Latin roots being variously estimated at more or less than half of the total, the next greatest element being Slavonic words, with the addition of some hundreds of Turkish, Greek, Albanian, and, in recent times, French words. Most Rumanians speak what is practically the same language—the Daco-Rumanian—throughout the kingdom. The Macedo-Rumanian (see KUTZO-VLACHS), south of the Danube and amongst the Balkans and Pindus, is largely modified by Greek; and the Istro-Rumanian, spoken by 2000 or 3000 in Istria and Croatia, has been much Slavonised.

The Rumanian language has been almost entirely kept alive by the common people, except for a brief period in the 17th century: the state, the church, and the aristocracy used Slavonic from the 6th to the 17th centuries, Greek under the Phanariot régime of the 18th century, and French during part of the 19th century. The first Rumanian book, a psalter, was printed in 1577, but the chronicles of the 17th century are the earliest specimens of national literature. Only about the middle of the 19th century can Rumanian literature be said to have flourished. France, both in politics and in art, gave an enormous impetus to Rumanian national life, classic authors of different countries, especially England, being retranslated from the French. Few countries have greater wealth of folk-lore and folk-song than Rumania, but no printed records

existed till the collection made in 1866 by Alexandri (q.v.), himself one of the most notable of native Rumanian poets. Contemporary with him were Bolintineanu and Alexandrescu. This renaissance of letters began with the foundation by the critic Maiorescu of the Yunimea Society in Jassy. Other writers are the novelist Dora d'Istria (see GHICA), the essayist Ion Ghika (q.v.), the poet Eminescu, the dramatist Caragiale, the novelists Sadoveanu and Voinesci, the poet Cerna, the historians Xenopol and Iorga, and the essayist Maren Beza.

See various standard works by N. Iorga, including his *History of Rumanian Land, People, Civilisation* (Eng. trans. 1926), and by A. D. Xenopol, including his *Histoire des Roumains* (1894) and *Les Roumains* (1909), also the vol. of memoirs of King Charles I., *Aus dem Leben König Karls von Rumänien* (1894-1900). In English, see Samuelson, *Rumanian, Past and Present* (1882); Strati-lesco, *From Carpathians to Pindus* (1906); M. Beza, *Rumanian People and Literature* (1920); V. Clark, *Greater Rumania* (1922); E. O. Hoppé, *In Gypsy Camp and Royal Palace* (1924); J. L. Evans, *The Agrarian Revolution in Rumania* (1924). In French, the history of F. Dané (1900); Stourdza, *La Terre et la Race roumaine* (1904); studies by Gubernatis (1898), Căteley (1908), Pittard (1919), and Gillard (1922); N. Xenopol, *La Richesse de Roumanie* (1916); and various economic works by Colescu (1903-13). In German, studies by Bergner (1897), Krauss (1916), Dungen (1916), Schmalz (1921), and Capitan (1926), and the histories of the literature by Gaster (1901), and Alexi (1906).

Rumex. See DOCK, SORREL, POLYGONACEÆ.

Rumford, COUNT. Benjamin Thompson, a man of many talents, was born of an old colonial stock at Woburn, in Massachusetts, on 26th March 1753. His youth was spent as an assistant in a goods store at Salem and at Boston, and as a school teacher. But having married a rich widow, he was made major in a New Hampshire regiment, and, through his royalist opinions, incurred the hostility of the colonists to such an extent that he found it best to cross the ocean to England (1775). In London he gave valuable information to the government as to the state of America, and was rewarded with an appointment in the Colonial Office. From his boyhood he had had a passion for physical investigations; in England he experimented largely with gunpowder, and was elected a Fellow of the Royal Society (1779). In 1782 he was back in America, with a lieutenant-colonel's commission in the king's army. After peace was concluded he was knighted, and entered the service of the Elector of Bavaria. In this new sphere he showed great reforming energy: he thoroughly reformed the army, drained the marshes round Mannheim, established in Munich a cannon-foundry and a military academy, cleared the country of the swarms of beggars and planned a poor-law system, spread widely the cultivation of the potato, disseminated a knowledge of cheap and good dishes (especially the Rumford soup) and foods, devised an economical fireplace, kitchen, and oven (the Rumford roaster), improved the breeds of horses and cattle in Bavaria, and laid out the English Garden in Munich. For these services he was rewarded by election to membership of the Academies of Science in Munich, Mannheim, and Berlin, by being put at the head of the War Department of Bavaria, and by being made a count of the Holy Roman Empire—he chose the title of Rumford, the former name of the town of Concord in New Hampshire. During the course of a visit to England in 1796 he endowed the two Rumford medals of the Royal Society of London, and he also endowed two similar medals of the American Academy of Science and Art, all four for researches in light and heat. Three years later was founded on his initiative the Royal Institution (q.v.) for diffusing the knowledge

of mechanical inventions. Going back to Munich in the same year, he found it threatened by the opposing French and Austrian armies. The Elector fled, leaving Count Rumford president of the Council of Regency, generalissimo of the forces, and head of the police. In 1799 he retired from the service of the Elector. His remaining years were principally occupied with physical investigations, especially in heat, which he clearly recognised to be some form of motion, besides showing that a definite quantity of heat could be produced by a definite amount of mechanical work. In 1804 he married the widow of Lavoisier, the celebrated chemist, and soon after settled at Auteuil, near Paris, where he died on 21st August 1814. See the Memoir by Ellis prefixed to his *Complete Works* (5 vols. London, 1876), and the *Life* by Bauernfeind (Munich, 1889).

Rumi, JALÂL-UDDIN. See PERSIA (*Literature*).

Ruminants, a name applied to those even-toed or Artiodactyl Ungulates which 'chew the cud.' These are (a) the Tragulidae, often called musk-deer; (b) the Cetylphora, including antelopes, sheep, goats, oxen, giraffes, deer; (c) the Camelidae, or camels and llamas. Their characteristics and the process of rumination are described in the article ARTIODACTYLA, with which those on DIGESTION and on CATTLE should be compared.

Rumphius, Latinised name of GEORG EBERHARD RUMPH (1687-1702), who, born at Hannau, became Dutch under-stadthouder at Amboyna. He was author of *Herbarium amboinense* and *Plinius indicus*, and a distinguished conchologist. His drawings of shells are marvellously accurate.

Rump Parliament. See LONG PARLIAMENT, CROMWELL.

Runcorn, a thriving manufacturing town and canal and river port of Cheshire, on the left bank of the tidal Mersey, 12 miles ESE. of Liverpool and 28 WSW. of Manchester. It is connected with Widnes on the Lancashire side of the river by a high railway viaduct (1864-69), and a transporter bridge (1902) which carries road traffic on a suspended platform. An ancient place, where a castle was founded by the Princess Ethelfleda in 916, and a priory in 1133, it yet dates its prosperity from the construction of the Bridgewater Canal (1762-72), which at Runcorn descends to the Mersey by a succession of locks. More canal-boats plied to and from Runcorn than any other place in the kingdom even before the opening of the Manchester Ship-canal (1887-94; see MANCHESTER and CANALS); and there are besides spacious docks with considerable shipping. Sole-leather and chemicals are the chief products. Other industries are boat-building and iron founding. Pop. (1851) 8049; (1871) 12,443; (1901) 16,491; (1921) 18,393.

Runeberg, JOHAN LUDVIG, the greatest poet who has written in Swedish, was born in Finland, at Jacobstad, on the Gulf of Bothnia, on 5th February 1804. His father, a retired sea-captain, gave him a good education; though from the time he entered (1822) the university of Åbo he supported himself. In 1830, after three years of private coaching, Runeberg was given a secretaryship in the university (removed to Helsingfors in 1827) and was named reader in eloquence (Latin literature), and in the following year added to these offices that of teacher in the lyceum. In these years he published his first books—in 1830 a volume of *Lyric Poems* and in 1831 a narrative poem, *The Grave in Perrho*, for which the Swedish Academy gave him its minor gold medal. Other books followed in quick succession, as a beautiful epic idyll, *The Elk-hunters* (1832), one of his finest pieces of work; a second volume of *Poems* (1833), contain-

ing amongst other things a second epic idyll, *Hanna*, which is almost equal to *The Elk-hunters* in beauty and finish of style; and a third, *Christmas Eve*. All three are written in hexameters, which Runeberg manages with admirable effect; like other poems of the same class, they deal with the rural life of the interior of Finland, *Hanna* with the joys and sorrows of the quiet parsonage, *The Elk-hunters* with the peasantry and country-folk, and *Christmas Eve* with the manor-house and its dependents. Runeberg describes the fresh, unconventional manners and the old-world, patriarchal style of living of these people with great wealth of picturesque detail, with excellent taste, with tender sympathy, with grace and simplicity and beauty of form. The atmosphere that envelops his poetry was the immediate creation of his own wholesome, healthy, manly temperament and genius; one sterling ingredient is a quaint natural humour, deep-sented and pure in quality. Runeberg's poetry is moreover the written embodiment of the deepest feelings and sentiments of the dual people of Finland, of the Finns no less than of the descendants of the Swedish immigrants, and with his name all Finlanders associate their passionate devotion to their country.

From 1832 Runeberg added to his already numerous duties those of editor of the bi weekly *Helsingfors Morning News*. But, with all these irons in the fire, he had too much work and too little pay, and there was little prospect of a good permanent position in the university; so in 1837 he applied for, and obtained, the post of reader of Roman Literature in the college of Borgå, where he spent the rest of his life, and died 6th May 1877. During these last years he wrote an epic of Russian life, *Nadeschda* (1841); a third volume of *Poems* (1843); an epic of old Norse times, *King Fjalar* (1844); *Ensign Stål's Stories* (2 vols. 1848 and 1860); a slight but merry little comedy, *Can't* (1862); a fine tragedy in the old Greek spirit, *The Kings in Salamis* (1863); and some short *Prose Writings* (1854). *King Fjalar* is, artistically, his greatest achievement, if not the greatest achievement in Swedish literature; but its fame has been eclipsed by Ensign Stål's glowing stories of Finland's heroic struggle against the giant Russia in 1808-9. The opening poem of the series, 'On land, our land,' has been fittingly chosen as the national song of Finland. In 1857, after four years' labour, Runeberg edited for the Lutheran Church of Finland a *Psalm-book*, in which were included above sixty pieces from his own pen. He also excelled as a translator of folk-songs from Serbian, German, and other languages. There is only one single poem in all his longer works that lacks the finished simplicity, beauty, and classic restraint which are so characteristic of him; that is a cycle entitled *Nights of Jealousy*, written in early youth.

See J. E. Strömberg's biography (4 parts, Helsingfors, 1880-96); and Söderlindh's (1904-96); Nyblom's preface to Runeberg's *Samlade Skrifter* (6 vols. Stockholm, 1873-74); and monographs (in Swedish) by Dietrichson and Rencken (Stockholm, 1864), Cygnäus (Helsingfors, 1873), and Vasenius (Helsingfors, 1890); a *Life* (in German) by Peschier (Stuttgart, 1881); and the preface to Eigenbrodt's excellent German translation of Runeberg's epic poems (2 vols. Halle, 1891). English readers will find a useful account of Runeberg's life, with specimens of his poems translated, in Gosse's *Northern Studies* (1879); a fairly faithful translation of his lyric poems, with a biographical notice, in Magnusson and Palmner's *Runeberg's Lyric Songs* (1878).

Runes (literally 'secrets,' 'mysteries,' 'whispers'), the letters of the oldest alphabet of the Germanic peoples, especially the Scandinavians and the English. In Sweden, Denmark, and Norway

thousands of inscriptions have been found. In England they are commonest in the north. They are rare in Germany. The Goths knew them before they became Christian, and Wulfila adopted some for his Gothic alphabet. In like manner the English retained the letters *wyn* and *thorn* (q.v.) when they took over the Irish alphabet.

The runic alphabet is called the Futhorc, from the first six letters *f, u, th, o, r, c*. The form, number, and value of the rune-staves changed considerably during the many centuries they were in use, and those of different countries exhibit considerable differences. They may, however, be arranged in three main divisions: (1) those of the earliest inscriptions (perhaps 3d or 4th century to 6th century) in a language not yet differentiated; (2) the Anglian runes, used in Northumbria from the 7th to the 9th century; (3) the later Scandinavian runes, used in Sweden and Norway in the 7th and following centuries. These futhorcs are shown in the table. The oldest is of twenty-four runes,

divided into three families or octaves. In the Anglian futhorc some new runes (not shown above) were obtained by differentiation, and the phonetic values underwent considerable changes. The Anglian runes are from 25 to 40 in number. The later Scandinavian futhorc, in which the greater number of runic inscriptions were written, had dwindled down to 16 runes. The names of the runes are given above in their Old English forms (*feoh*, 'wealth'; *ur*, 'aurochs'; *thorn*, 'thorn,' &c.). There have been preserved verses in Old English, Norwegian, and Icelandic, descending upon the significance of these names.

The origin of the runic writing has been a matter of prolonged controversy. Isaac Taylor held that it was derived from a northern Greek alphabet of about the 6th century, B.C.; Wimmer from the Latin alphabet; Von Friesen from both Greek and Latin. The forms of the runes were considerably modified by the fact that they were cut with a

knife on wooden slabs; consequently horizontal strokes, which would follow the grain of the wood, are necessarily avoided, and all the strokes are either vertical or slanting. This accords with the famous passage in the Old English poem *The Husband's Message*. Naturally the inscriptions that survive are mostly on more durable materials—stone and metal.

There are several interesting runic inscriptions in Britain, among which may be mentioned that on the Ruthwell (q.v.) Cross in Dumfriesshire, and that on the Bewcastle (q.v.) Cross in Cumberland, a fac-simile of which is given here. It is a memorial of Ælfred, son of Oswin, king of Northumbria, and dates from the 7th century. Several crosses in the Isle of Man are carved with the old Irish interlaced ornament, and are in the form of the old Irish cross. As they have also runic inscriptions, this style of Irish ornament has wrongly acquired the name of runic knot-work, and the Irish form of cross is often called the runic cross. These names originated at a time when archaeological knowledge was less advanced than it is now, and should be rejected.

Fac-similes of the chief runic inscriptions have been conveniently collected by Dr G. Stephens of Copenhagen in his *Handbook of Runic Monuments* (1884), which is an abridgment of his larger work on the *Old Northern Runic Monuments* (1 vol. 1866-1901). See Isaac Taylor, *The Alphabet* (1883), and *Greeks and Goths: a Study on the Runes* (1879); the works of Dr Wimmer, Dr Ingge, and Von Friesen; and *Runic and Heroic Poems of the Old Teutonic Peoples* (ed. Bruce Dickins, 1915).

Runn of Cutch. See CUTCH.

Runner, in Botany, is a long, slender branch proceeding from a lateral bud of a herbaceous plant with very short axis, or, in popular language, without stem. It extends along the ground, and produces buds as it proceeds, which often take root and form new plants. Strawberries afford a familiar example. Another is found in *Potentilla anserina*. Runners are common in the genus *Ranunculus*.

Runners. See BEAN.

Runnimead, a long stretch of green meadow, lying along the right bank of the Thames, 1 mile above Staines and 36 miles by river WSW. of London. Here, or on Chert Island, a little way off the shore, Magna Carta (q.v.) was agreed to by King John, 15th June 1215.

Running. See ATHLETIC SPORTS.

Runrig Lands, or, as they are variously called, runridge or rundale lands, formerly frequent in Ireland and Scotland, are survivals of the simple form of open-field husbandry by a village community. Under this system the arable portion of the area of land occupied by a group of families, forming a township or village community, was periodically distributed among the families of the community, the share allotted to each family consisting of discontinuous rigs or strips of the open field; the pasture-land was held in common (see LAND LAWS). With the increasing tendency towards the recognition of separate proprietary rights, redistribution became more and more rare, and then ceased altogether. In the result, while the pasture-land continued to be held in common, the arable land came to be parcelled out

in severalty among individual proprietors, forming a congeries of small detached and interspersed estates. It was also formerly a common practice in Scotland, when an estate had to be divided among heir-portioners or adjudgers, to parcel it out by 'kavels,' or, in other words, in the form of runrig, the alternate ridges being allotted to separate proprietors. The obstruction to agricultural improvement resulting from the land being thus dispersed in small parcels intermixed with each other led in Scotland, in the end of the 17th century, to the introduction of a process of compulsory apportionment of such lands. By Statute 1695, chap. 23, it was provided that 'wherever lands of different heritors be runrig,' application may be made to the judge ordinary, or justices of the peace, 'to the effect that these lands may be divided according to their respective interests.' By this process, which is really a process of excambion or exchange, the land is apportioned so that each of the proprietors thereafter has his holding in one or more compact blocks which can be enclosed. This remedy, however, does not apply to burch acres or to parcels of land exceeding four acres in extent. The Small Landholders (Scotland) Act, 1911, sect. 24 (6), gives to the Land Court, on application by the parties interested, wide discretionary powers to apportion land held runrig among the holders thereof.

Ruppee, a silver coin current in India, of the value of 2s. English (see INDIA). A lac (or lakh) of ruppees is 100,000 (at the old value of 2s. = £10,000), and a crore is 10,000,000. Coins are struck in silver of the value of 1, 2, $\frac{1}{2}$, $\frac{1}{4}$, and $\frac{1}{8}$ rupee. The first rupee was struck by Sher Shah, the Afghan emperor of Delhi (1540-45), and was adopted by Akbar and his successors; but in the decline of the Mohammedan empire every petty chief coined his own rupee, varying in weight and value, though usually bearing the name and titles of the reigning emperor. The rupee is the official money of account in the island of Mauritius.

Rupert, PRINCE, third son of the Elector Palatine Frederick V. and Elizabeth, daughter of James I. of England, was born at Prague on 18th December 1619, his parents having the month before been crowned king and queen of Bohemia. He studied at Leyden, and became well grounded in mathematics and religion ('indeed, made Jesuit-proof'), as well as in French, Spanish, and Italian, and above all the art of war. After a year and a half at the English court, where it was proposed to make a bishop of him or viceroy of Madagascar, he served in 1637-38, during the Thirty Years' War, against the Imperialists, until at Lengo he was taken prisoner, and confined for nearly three years at Linz. In 1642 he returned to England, in time to be present at the raising of the king's standard at Nottingham; and for the next three years the 'Mad Cavalier' was the life and soul of the royalist cause, winning many a battle by his resistless charges, to lose it as often by a too headlong pursuit. He had fought at Worcester, Edgehill, Brentford, Chalgrove, Newbury, Bolton, Marston Moor, Newbury again, and Naseby, when in August 1645 his surrender of Bristol after a three weeks' siege so irritated Charles, who the year before had created him Duke of Cumberland and generalissimo, that he curtly dismissed him, and sent him his passport to quit the kingdom. A court-martial, however, completely cleared him, and he resumed his duties, only to surrender at Oxford to Fairfax in the following June. He now took service with France, but in 1648 accepted the command of that portion of the English fleet which had espoused the king's cause. As admiral or corsair, Prince Rupert acquitted himself with all

his old daring and somewhat more caution; and for three years he kept his ships afloat, escaping at last the blockade in which for nearly a twelve-month he was held at Kinsale on the Irish coast by Blake. But in 1651 the latter attacked his squadron, and burned or sunk most of his vessels. With the remnant the prince escaped to the West Indies, where, along with his brother Maurice, till the loss of the latter in a hurricane (1652), he led a buccaneering life, maintaining himself as before by the seizure of English and other merchantmen. In 1653 he was back in France, where and in Germany he chiefly resided till the Restoration. Thereafter he served with distinction under the Duke of York, and, in concert with the Duke of Albemarle, in naval operations against the Dutch; and he died at his house in Spring Gardens, 29th November 1682, in the enjoyment of various offices and dignities, being a privy-councillor, governor of Windsor, an F.R.S., &c. He left a natural daughter, Ruperta, born to him in 1673 by Margaret Hughes, actress. His last ten years had been spent in retirement in the pursuit of chemical, physical, and mechanical researches, for which he evinced considerable aptitude. Though he was not the inventor of mezzotint (see ENGRAVING), Prince Rupert no doubt improved the processes of the art, which he described to the Royal Society in 1662, after executing several interesting engravings on the new principle. Among his discoveries were an improved gunpowder, the composition known as 'Prince's metal,' and perhaps the 'Prince Rupert's Drops,' or curious glass bubbles described under Annealing (q.v.).

See Eliot Warburton's *Memoirs of Prince Rupert and the Cavaliers* (3 vols. 1849); Lord Ronald Gower's *Rupert of the Rhine* (1890); Eva Scott, *Rupert, Prince, Palatine* (1899); Miss Erskine, *A Royal Cavalier* (1910).

Rupert's Land. See HUDSON'S BAY COMPANY.

Rupia is a somewhat severe form of skin disease. It is characterised by flattish, distinct *bullæ* or blebs, containing a serous, purulent, or sanious fluid, which become changed into thick scabs. Several varieties of this disease have been established by dermatologists. In its simplest form the blebs are not preceded by any inflammatory symptoms, are about an inch in diameter, and contain a fluid which is originally thin and transparent, but soon thickens, becomes purulent, and dries into brown, ragged scabs, which are elevated in the centre. The scabs are easily separated, and leave ulcerated surfaces, on which several successive scabs usually form before healing ensues. In a more severe form, known as *Rupia prominens*, the scab projects so much in the centre as to resemble a limpet-shell in form.

Rupia is a chronic disease, and is usually limited to the limbs, the loins, and the nates. It is not contagious, and generally attacks persons debilitated by old age, intemperance, bad living, or previous diseases, especially smallpox, scarlatina, and syphilis. The general treatment consists mainly in the administration of tonics, the mineral acids, ale, wine, animal food, &c.; and there is no doubt that certain cases, especially those caused by syphilis, which will not yield to tonics, rapidly improve when treated with iodide of potassium. The local treatment consists in puncturing the blebs as soon as they arise, in removing the scabs by poulticing, and in applying a slightly stimulating application—such as a solution of nitrate of silver—to the subjacent ulcers. The disease is frequently tedious and obstinate, but the patient almost always ultimately recovers.

Ruppin, NEG, a town of Prussia, on a lake (Ruppin See), which communicates with the

Elbe, 48 miles by rail N.W. of Berlin. It was built by Frederick William II. after a fire in 1787, and is a handsome town with a 13th century abbey church. Pop. 17,000.

Rupture. See HERNIA.

Rural Dean. See DEAN.

Rurik, the founder of the Russian monarchy. See NORTHMEN, and RUSSIA.

Rurki, a town in the United Provinces of India, 22 miles E. of Saharanpur, with an engineering college and meteorological observatory. Pop. 16,700.

Rush, BENJAMIN, an American physician, was born in what is now the twenty-third ward of Philadelphia, December 24, 1745, graduated at Princeton in 1760, studied medicine in Philadelphia, Edinburgh, London, and Paris, and in 1769 was made professor of Chemistry in the Philadelphia Medical College. Elected a member of the Continental Congress, he signed the Declaration of Independence (1776). In April 1777 he was appointed Surgeon-general, and in July Physician-general, of the Continental army. His duties did not prevent him from writing a series of letters against the articles of confederation of 1776. In 1778 he resigned his post in the army, because he could not prevent frauds upon soldiers in the hospital stores, and returned to his professorship. He was a founder of the Philadelphia dispensary, the first in the United States, and of the College of Physicians, was active in the establishment of public schools, was a member of the state conventions which ratified the Federal constitution and formed the state constitution. He next became professor of the Theory and Practice of Medicine at Philadelphia, to which chair he added those of the Institutes and Practice of Medicine and Clinical Practice (1791), and of the Practice of Physic (1797); and during the epidemic of 1793 he was as successful as devoted in the treatment of yellow fever. Violently attacked, owing to his methods of practice, by William Cobbett, who published a newspaper in Philadelphia, he prosecuted him for libel, and recovered \$5000 damages. In 1799 Rush was appointed treasurer of the United States Mint, which post he held till his death, 19th April 1813. He was called 'the Sydenham of America,' and his medical works brought him honours from several European sovereigns. The chief of them were *Medical Inquiries and Observations* (5 vols. 1789-93), *Essays* (1798), and *Discourses of the Mind* (1821; 5th ed. 1835).—His son, RICHARD (1780-1859), a lawyer and statesman, was minister to England in 1817-25, where he negotiated the important Fisheries and North-eastern Boundary Treaties, and was Secretary of the Treasury from 1825 to 1829. In 1828 he was an unsuccessful candidate for the vice-presidency of the United States; and in 1836-38 he secured for his country the whole of the legacy which James Smithson had left to found the Smithsonian Institution.

Rush (*Juncus*), a genus of plants of the family Juncaceæ, having a glume-like (not coloured) perianth, smooth filaments, and a many-seeded, generally three-celled capsule. The species are numerous, mostly natives of wet or marshy places in the colder parts of the world; some are found in tropical regions. Some are absolutely destitute of leaves, but have barren scapes (flower-stems) resembling leaves; some have leafy stems, the leaves rounded or somewhat compressed, and usually jointed internally; some have plane or grooved leaves on the stems; some have very narrow leaves, all from the root. The name Rush perhaps properly belongs to those species which have no

proper leaves; the round stems of which, bearing or not bearing small lateral heads of flowers, are popularly known as *Rushes*. The Soft Rush (*J. effusus*) is cultivated in Japan for making mats.

The Common Rush (*J. conglomeratus*) and the Soft Rush are largely used for the bottoms of chairs and for mats, and in ruder times, when carpets were little known, they were much used for covering the floors of rooms; to this many allusions will be found in old writers. As they were seldom entirely renewed, the insanitary consequences may be imagined. The strewing of churches grew into a religious ceremony, and has been revived in modern times, as at Grasmere. The stems of the true rushes contain a large pith or soft central substance, which used to be used for wicks to small candles, called rushlights. There are twenty or twenty-four British species of rush, some of which are very rare, some found only on the highest mountains, but some are among the most common of plants. They are often very troublesome weeds to the farmer. Thorough drainage is the best means of getting rid of them. Lime, dry ashes, &c. are also useful.

Common Rush (*Juncus conglomeratus*).

Rush-nut (*Cyperus esculentus*). See CYPERUS.

Rushworth, JOHN, whose *Historical Collections of Privy Passages of State, Weighty Matters of Law, Remarkable Proceedings in Five Parliaments*, is an important contribution to our knowledge of the Civil War, and the events that led to it, belonged to an ancient family in Northumberland, and was born there about 1607. He studied at Oxford, and settled in London as a barrister. He appears to have spent a great deal of his time for many years in attending the Star Chamber, the Court of Honour, the Exchequer Chamber, Parliament, &c., and in taking down shorthand notes of the proceedings. When the Long Parliament met in 1640 he was appointed assistant to Henry Elsynge, clerk of the House of Commons. He sat in parliament as member for Berwick; was in 1645 secretary to Sir Thomas Fairfax, and in 1677 to the Lord Keeper of the Great Seal. In 1684 he was hung into the King's Bench for debt, and here he died, 12th May 1690. Rushworth's *Historical Collections* cover the period 1618-48, and were published in four instalments—in 1659, 1680, 1692, and 1701. The whole was republished in 1721 in 7 vols. Rushworth had the instinct of perpetuity; for he sets forth as the motive for his labour 'the impossibility for any man in after ages to ground a true History, by relying on the printed pamphlets of our days, which passed the press while it was without control.' The work has been blamed by royalist authors as unfair, and Carlyle often rails on its worthy author as a Divesdust.

Ruskin, JOHN, the most eloquent and original of all writers upon art, and a strenuous preacher of righteousness, was born in London, 8th February 1819. He was an only child; his father (1785-1864), a wealthy wine-merchant, was an Edinburgh man settled in London. He was educated in his father's house, first in London and afterwards at Denmark-hill, till he went, as a gentleman commoner of Christ Church, to Oxford. There he gained the

Newdigate prize for English poetry—by a poem on *Salsette and Elephantia*—in 1839, and took his degree in 1842. He studied painting under Copley Fielding and Harding; but his masters in the art were, he says, Rubens and Rembrandt. The story of the earlier years of his life has been told by Ruskin himself very fully in his *Praterita*, one of the most charming autobiographies in the language. In 1843 appeared the first volume of his *Modern Painters*, the primary design of which (in reply to a criticism of Turner in *Blackwood's Magazine*) was to prove the superiority of modern landscape-painters, and more especially of Turner, to the Old Masters; but in the later volumes (the fifth and last was published in 1860) the work expanded into a vast discursive treatise on the principles of art, interspersed with artistic and symbolical descriptions of nature, more elaborate and imaginative than any writer, prose or poetic, had ever before attempted. *Modern Painters* was essentially revolutionary in its spirit and aim, many of the most distinguished landscape-painters, both of old and new schools, being summarily dealt with and condemned; and the work naturally excited the aversion and hostility of the conservatives in art. But the unequalled splendour of its style gave it a place in literature; the originality of its views, the lofty conception of the painter's art displayed in it, and the evident justness of much of the criticism, secured recognition. Disciples soon appeared; and the views of art enunciated by Ruskin gradually made way, and largely determined the course and character of later English art. The first volume was published in a much altered form in 1846. The last three volumes contained illustrations by the author. A revised and altered edition appeared in 1860-67; another in 1873; and an edition in six volumes, with some additional plates, an epilogue, and new index, in 1889. In 1849 appeared *The Seven Lamps of Architecture*; and in 1851-53 *The Stones of Venice*, both being efforts to introduce a new and loftier conception of the significance of domestic architecture. They were exquisitely illustrated by the author himself. About this time Pre-Raphaelitism (q.v.) began to develop itself as a distinctive phase of modern art, and Ruskin warmly espoused its cause in letters, pamphlets, and *Notes on the Academy Exhibition* (1855-60). He was the earliest literary advocate of this school, whose leading principle he defined as the resolve 'to paint things as they probably did look and happen, not as, by rules of art developed under Raphael, they might be supposed gracefully, deliciously, or sublimely to have happened.'

In 1854 he published four admirable and suggestive *Lectures on Architecture and Painting*; and in 1858 two *Lectures on the Political Economy of Art*. The *Notes on the Construction of Sheepfolds* (1851), dealing with the discipline of the church, illustrate his ingenuity in devising picturesque titles that suggest no notion of the subject treated. *The King of the Golden River*, a fairy story, was published in 1851; and in 1854 *The Two Paths*, lectures on art and its application to decoration and manufacture. The *Elements of Drawing* and the *Elements of Perspective* appeared in 1857 and 1859. The *Crown of Wild Olive* is a series of four essays on work, traffic, war, and the future of England; *Sesame and Lilies*, lectures on good literature. *The Queen of the Air* is a study of the Greek myths of cloud and storm; *Ethics of the Dust*, lectures on crystallisation; *Ariadne Florentina*, on wood and metal engraving; *Aratra Pentelici*, on the principles of sculpture. The *Laws of Fesolè* are the elements of painting and drawing; *Frondes Agrestes* are readings from 'Modern Painters'; *Giotto and His Works, Love's Meinic* (on Birds),

and *Deucalion* (on Geology) are other publications. *Munera Pulveris* contains the elements of political economy according to Ruskin; while *Unto this Last*—in Ruskin's opinion, the best of his works—attacks the current doctrines of the 'dismal science.' *Val d'Arno* contains lectures on the art of the 13th century in Pisa and Florence; later courses dealt with the modern art of England and English history (*Pleasures of England*). *Mornings in Florence* are studies of Christian art for English travellers; and *St Mark's Rest* is on the history of Venice. *The Eagle's Nest* discusses the relation of natural science to art; *Time and Tide* are letters to a working-man of Sunderland. *Arrows of the Chace* is a selection of his letters; *On the Old Road* is the title of a republication of his miscellaneous pamphlets, articles, and essays contributed to various reviews and magazines, containing famous utterances on Samuel Prout, the History of Christian Art, the Lord's Prayer, the 'Cestus of Aglaia,' &c. An early volume of poems, issued for private circulation, became a much sought after bibliographical treasure; in 1891 it was reprinted (in 2 vols.) with many additional pieces and illustrations from the author's drawings. *Fors Clavigera* appeared as a sort of periodical at irregular intervals for several years, in the form of letters to the workmen and labourers of Great Britain, on a great variety of topics (vols. i. viii. with full index, 1887). *Proserpina*, published in the same way, gives studies of wayside flowers. *Hours Included* (1887) is a series of letters 'to the ladies of the Thwaite.' From 1869 till 1879 Ruskin was Slade professor of Art at Oxford; in 1871 he gave £5000 for the endowment of a master of drawing there; in 1883 he was re-elected professor, but resigned in the following year. Subsequently he founded a museum at Sheffield, where he bestowed part of his own priceless library and art treasures. In his later years he established himself at Brantwood, on Conistone Lake. There he died on the 20th of January 1900.

Ruskin was primarily a critic of art; but, as the titles of his works indicate, his teaching extended over a wide area. Art for him was closely and inseparably bound up with truth, with morals, with religion; and in most departments of political philosophy, in social and political economy, Ruskin was constant, in season and out of season, in lifting up his testimony against what he conceived to be low views, perverted ideals, coarse and vulgar complacencies. Like Carlyle, whose pupil he professed to be, he held the world in these later days to have gone on a wrong tack; in his views of nature and life he was, he said, 'alone in the midst of a modern crowd, which rejects them all,' and had to 'maintain himself against the contradiction of every one of his best friends.' Within the sphere of art criticism he declares that an important part of his lifework had been to teach 'the supremacy of five great painters, despised till he spoke of them—Turner, Tintoret, Luini, Botticelli, and Carpaccio.' His life-long contention with political economy is based on the belief that the science had been used to inculcate the unchecked and competitive pursuit of merely material wealth. He affirms broadly that his *Munera Pulveris* contains the first accurate analysis of the laws of political economy which had been published in England. What is usually called political economy is in reality nothing more than the investigation of some accidental phenomena of modern commercial operations, and has no connection with political economy as treated by the great thinkers of the past—such as Plato, Xenophon, Cicero, Bacon. True political economy regulates the acts and habits of a society or state, with reference to its maintenance, as domestic economy does those of a household. It

is neither an art nor a science, but a system of conduct and legislation, founded on the sciences, directing the arts, and impossible except under certain conditions of moral culture. By the maintenance of the state, which is the object of political economy, is to be understood the support of its population in healthy and happy life, and the increase of their numbers, so far as is consistent with their happiness. It is the 'multiplication of human life at the highest standard,' cherishing and developing the noblest type of manhood, alike in beauty, in intelligence, and in character. The wealth of which Ruskin takes cognisance is not mere exchangeable value, but intrinsic and effectual wealth, consisting of things contributing to the support of life in its fullest sense—as land, houses, furniture, instruments, food, medicine, clothing, books, works of art. The subject of political economy, therefore, embraces a large part of the sphere of private and public morals, and of political philosophy. It deals with the relation of master to servant, employer to workman, of the state to its subjects, with the province of sanitary and commercial legislation, and with the duty of the state in promoting education, suppressing luxury, regulating the hours and wages of labour. He is as confident as the most revolutionary reformer that the conditions of modern society must be completely changed and reconstructed; his ideals coincide in many points with those of some Socialists, though many of his aims would be regarded as distinctly reactionary. A 'violent illiberal' rather than a conservative, Ruskin regards reverence for natural beauty, truth, and godliness as the highest elements in life, and would give properly constituted authority extensive powers; usury of any kind is as indefensible as avarice or dishonesty. Till of late he was seldom treated as a serious political economist; but it has recently been admitted that he has actually pointed out some real weaknesses of the old abstract political economy as a scientific theory. He devoted a great part of his originally large fortune to founding the St. George's Guild, which was intended to be a kind of primitive agricultural community, where the old-world virtues should be strenuously inculcated on young and old, and where ancient and homely methods might be cherished in defiance of all modern mechanical and manufacturing processes. He also strove to promote home industries in various places. Not more remarkable than the eloquence, power, and richness of his English style are the confidence and dogmatism of his assertions, the audacity of his paradoxes, the fearlessness of his denunciations; while his earnestness, conviction, and self-denying honesty of purpose are undisputed. His influence in creating a new interest in the beauty of nature and of art in England was profound; and although the world rejects his theories of social economy as perverse, paradoxical, and impracticable, he did much to vivify ideals of life, and ennoble our standards of conduct.

See E. T. Cook, *The Life of Ruskin* (2 vols. 1911); W. G. Collingwood, *The Life and Work of John Ruskin* (2 vols. 1893; new ed. 1900); monographs by Mrs. Meynell (1900) and Frederic Harrison (1902); French works on him by Bardoux (1900) and Sizleranne (1897; trans. 1900), and German by Charlotte Broicher (1904-8). A collected edition of the works (39 vols.) appeared in 1903-12, edited by Cook and Wedderburn, with a bibliography, and an index which is practically a concordance.

Ruskin College, a college established at Oxford in 1899 to provide education in social sciences for working-class students. It is supported by subscriptions from trade unions, co-operative societies, and other associations and individuals. New buildings were opened in 1913. The Central

Labour College was the result of the secession in 1909 of students and unions dissatisfied with its tendency and favouring a more definitely class-conscious point of view. The Central Labour College removed to London in 1911.

Russell, a great Whig house, whose origin has been traced back to Thor, through 'Olaf the sharp-eyed, king of Reik,' Drogo, brother of Rollo, the first Duke of Normandy, and Hugh Bertrand, lord of Le Rozel, a follower of the Conqueror's. Anyhow, a John Russell was constable of Corfe Castle in Dorsetshire in 1221; and his descendants have had seats at Kingston Russell, near Dorchester; Cheneys, in Bucks, near Amersham; and Woburn Abbey, in Bedfordshire. Among them, besides William Lord Russell, Earl Russell, and Bertrand Russell (all noticed separately below), the following may be mentioned: Sir John Russell, who

in 1594 became Lord Deputy of Ireland, and in 1603 was created Baron Russell of Thornhaugh; Francis, fourth Earl (died 1641), the drainer of the Bedford Level; William, fifth Earl, created in 1694 Marquis of Tavistock and Duke of Bedford; Admiral Edward Russell (1651-1727), who, semi-Jacobite though he was, beat the French at La Hogue in 1692, and for his victory was made Earl of Orford; John, fourth Duke (1710-71), Lord-lieutenant of Ireland; his grandson, Lord William Russell (1767-1840), who was murdered by his valet Convoisier; Odo (1829-84), brother of the ninth Duke, from 1871 ambassador to Germany, in 1881 made Baron Amptill; and George William Eskine (1853-1919), grandson of the sixth Duke, essayist and under-secretary.

See J. H. Wotton's *Historical Memoirs of the House of Russell* (1833); and Froude's *Short Studies* (4th series, 1884).

WILLIAM RUSSELL, LORD RUSSELL, was born 29th September 1639, third son of the fifth Earl of Bedford by Lady Anne Carr, daughter of the poisoner Countess of Somerset; by the death of his brothers (one in infancy, the other in manhood) he, in 1678, succeeded to the courtesy title of Lord Russell. He was educated at Cambridge, and travelled on the Continent. At the Restoration he was elected M.P. for Tavistock, and was 'drawn by the court into some disorders' (debts and duelling), from which he was rescued by his marriage in 1669 with Lady Rachel Wrothesley (1636-1723), second daughter and co-heiress of the Earl of Southampton and widow of Lord Vaughan. He was a silent member till 1674, when he spoke against the doings of the Cabal, and thenceforth we find him an active all wit in

the Duke of York's rebellion, and in 1688 the Exclusion Bill up to the House of Lords. The king and his brother resolved to be revenged on him and the other leaders of the Whig party; and he, Essex, and Sidney were arrested as participants in the Rye-house Plot. On 13th July 1688 he was arraigned of high-treason at the Old Bailey, and, infamous witnesses easily satisfying a packed jury, was found guilty. His father's proffer, through the Duchess of Portsmouth, of £100,000 for his life availed nothing, nor his own solemn disavowal of any idea against the king's life or any contrivance of altering the government; and on the 21st he was beheaded in Lincoln's Inn Fields. The pity of his judicial murder, the pathos of Burnet's story of his end, and the exquisite letters of his noble wife, who at his trial appeared in court as his secretary, have

secured him a place in history that else he had never attained to, for he was a man of virtues, not genius, a Christian hero rather than a statesman.

See his life by Lord John Russell (1819; 4th ed. 1853); the Letters of Lady Russell (1773; 14th ed. 1853); and the Lives of her by Miss Berry (1819), Lord John Russell (1820), and Guizot (Eng. trans. 1855).

JOHN RUSSELL, EARL RUSSELL, K.G., was born on 18th August 1792, in Hertford Street, Mayfair, London, the third son of the sixth Duke of Bedford. A sickly child, he was educated at Sunbury, at Westminster (1803-4), and then at Woodnesborough vicarage, near Sandwich, until, in 1809, after a nine months' visit with Lord and Lady Holland to Spain and Portugal, he entered the university of Edinburgh. He lived there three years with Professor Playfair, studying under Dugald Stewart and Dr Thomas Brown, first exercising his powers of debate at the meetings of the Speculative Society, and paying two more visits to the Peninsula. In July 1813, while still a minor, he was returned for the family borough of Tavistock, but, though he spoke in 1815 against the renewal of war with France, foreign travel and literature for some years engrossed him rather than politics. He made his first motion in favour of parliamentary reform in 1819, and continued to bring the subject almost annually before the House. He was also the strenuous advocate of the repeal of the Test and Corporation Acts, of Catholic Emancipation, and of other measures of civil and religious liberty. At the general election of 1830, caused by the death of George IV., the rallying cry of reform won many fresh seats for the Liberals; the 'Great Duke' was driven from office, and Earl Grey proceeded to form a ministry. Lord John became Paymaster of the Forces, without a seat in the cabinet; but he was one of the four members of the government entrusted with the task of framing the first Reform Bill, and on him devolved the great and memorable honour of proposing it. The fortunes of the measure belong to the history of the day; enough that on 4th June 1832 it received the royal assent, and the country was saved from the throes of revolution that at one time seemed imminent. In November 1834 Lord John left office with the Melbourne government, which had succeeded Grey's; in March 1835 he brought forward a motion in favour of applying the surplus revenues of the Irish Church to educational purposes; and the success of his motion caused the downfall of Peel and the return of Melbourne to power.

As Home Secretary and leader of the Lower House Lord John now attained the zenith of his career, four measures with which his name is associated being the Municipal Reform Act (1835), and the Tithes Commutation, Registration, and Marriage Acts (1836). In 1839 he exchanged the seals of the Home for those of the Colonial Office; in 1841 he proposed a fixed duty of 8s. per quarter on foreign corn and a reduction of the duties on sugar and timber. Defeated by the opposition, the Melbourne government appealed to the country without success, so once more made way for Peel. In this general election Lord John, who meanwhile had sat for Hants, Bandon Bridge, Devon, and Stroud, boldly challenged the verdict of London on free trade by standing for the City. He was returned by the narrow majority of 9, and continued to represent the City until his elevation to the Upper House.

In November 1845 he wrote a letter from Edinburgh to his London constituents, announcing his conversion to the total and immediate repeal of the Corn Laws. This letter led to Peel's resignation; and Lord John on 11th December was commissioned by the Queen to form an administration.

He failed, however, owing to Lord Grey's antipathy to Palmerston, so Peel was forced back to office, and carried the repeal. On the very day on which the bill passed the Lords the Peel ministry was defeated in the Commons on a question of Irish coercion by a coalition of Whigs and Protectionists, whereupon a Whig ministry succeeded, with Lord John for prime-minister (1846). It succeeded to a difficult position. In Ireland there was the famine, followed by a foolish rebellion, whilst at home there was Chartism and the so-called 'Papal aggression,' which evoked from Lord John an indignant protest, first in the form of a letter to the Bishop of Durham, and next in the Ecclesiastical Titles Bill of 1851. In the winter of that year Lord Palmerston's approval of the French *coup d'état* without the Queen's or Lord John Russell's knowledge procured him his dismissal from the office of Foreign Secretary; within two months he 'gave Russell his tit-for-tat,' defeating him over a militia bill (February 1852). After a short-lived Derby government, Lord Aberdeen in December formed a coalition ministry of Whigs and Peelites, with Russell for Foreign Secretary and leader in the Commons.

His inopportune Reform Bill (1854), the Crimean mismanagement, his resignation (January 1855), and his bungling that same year at the Vienna Conference, all combined to render him thoroughly unpopular; and for four years he remained out of office. But in June 1859, in the second Palmerston administration, he became Foreign Secretary, which office he held six years, having meanwhile in 1861 been created Earl Russell. He did much for the cause of Italian unity; still, non-intervention was his leading principle—e.g. during the American civil war and the Schleswig-Holstein difficulty. On Palmerston's death in 1865 Earl Russell for the second time became prime-minister, but the defeat in the following June of his new Reform Bill left no alternative but resignation. He continued, however, busy with tongue and pen till his death, which took place at his residence, Pembroke Lodge, Richmond Park, on 28th May 1878.

The 'Lycurgus of the Lower House,' as Sydney Smith dubbed him, this 'little great man' was honest in all his convictions, in none more so than in his belief in himself. 'He knew he was right' gives the key to both his career and his character. Of his voluminous works, a score in number, including a tale and two tragedies, need only be mentioned his *Life of William Lord Russell* (1819), *Memoirs of the Affairs of Europe* (1824), *The Correspondence of John, fourth Duke of Bedford* (3 vols. 1842-46), and the *Memoirs of Fox and Moore*.

See his *Selections from Speeches and Despatches* (1870), his *Recollections and Suggestions* (1875), *Early Correspondence* (ed. Rollo Russell, 2 vols. 1913), *Later Correspondence* (ed. G. P. Gooch, 2 vols. 1925), and *Spencer Walpole's Life of Lord John Russell* (2 vols. 1889).

BERTRAND RUSSELL, F.R.S., mathematician and philosopher, and grandson of the foregoing, was born at Trelleck, 18th May 1872, and studied at Trinity College, Cambridge. He had already achieved fame as a brilliant philosophical and mathematical thinker and writer, when, on the outbreak of war, his no-conscription writings brought him fine imprisonment, and loss of a Cambridge lectureship. He visited Russia, where, a communist, he was disappointed in the Soviet experiment; and China, where he gave a course of lectures in Peking University. His books include *Philosophy of Leibniz* (1900), *Principles of Mathematics* (1903), *Philosophical Essays* (1910), *Principia Mathematica* (with Dr A. N. Whitehead, 1910), *Problems of Philosophy* (1911), *Principles of Social Reconstruction* (1917), *Mysticism and Logic*

(1918), *Mathematical Philosophy* (1919), *Practice and Theory of Bolshevism* (1920), *ABC of Atoms* (1923), *Prospects of Industrial Civilisation* (with his second wife, 1923), *Analysis of Mind* (1925), *A B C of Relativity* (1925), *On Education* (1926).

Russell, GEORGE WILLIAM, Irish writer under the pseudonym of 'A. E.', was born at Lurgan, Co. Armagh, in 1867. His collected poems were published in 1913; he has also published a prose drama *Deirdre* (1907), *The Candle of Vision* (in prose, 1918), *Interpreters* (1922), and various essays and works on Irish political matters. He is known besides as a painter, a promoter of Irish agriculture, one of the founders of the Irish Literary Theatre (1899), and an enthusiastic supporter of Irish nationalism. See the Study by D. Figgis, 'A. E.' (1916).

Russell, WILLIAM CLARK (1844-1911), a popular nautical novelist, was born in New York, son of the singer and song-composer, Henry Russell (1812-1900). Educated at Winchester and in France, he went to sea at thirteen for about eight years, then wrote for the Newcastle *Daily Chronicle* and the London *Daily Telegraph*, but from 1887 reserved his energies mainly for fiction.

Russell, SIR WILLIAM HOWARD (1821-1907), the first of 'special correspondents,' was born at Lilyvale in County Dublin, educated at Trinity College, Dublin, joined the staff of the *Times* in 1843, and was called to the bar in 1850. He went out to the Crimea at the beginning of the war, and there remained till the close, writing home those famous letters which opened the eyes of Englishmen to the shameful sufferings of the soldiers during the winter siege of 1854-55, and quickly brought about the fall of the Aberdeen ministry. He next witnessed the events of the Indian Mutiny, returning to England in 1858. He established the *Army and Navy Gazette* in 1860, and next year the opening of the civil war drew him to America, which he soon made too hot for him by a too truthful account of the Federal defeat at Bull Run. He accompanied the Austrians during the war with Prussia (1866), and the Prussians during the war with France (1870-71); visited Egypt and the East (1874) and India (1877), as private secretary to the Prince of Wales; and went with Wolsley to South Africa in 1879. Most of his letters were collected into volumes, which had great success in their day; three books that may be named are *The Adventures of Doctor Brady* (1868), a novel; *Hesperotheren, or Notes from the West* (1882); and *A Visit to Chile and the Nitrate Fields of Tarapacá* (1890).

Russia, a federation of Soviet republics in eastern Europe and northern and western Asia, extending from the Black Sea to the Arctic Ocean, and from the Gulf of Finland to the North Pacific, bordering on Japan (in Sakhalin), China, Afghanistan, Persia, Turkey, Rumania, Poland, Latvia, Esthonia, and Finland, and coming uncomfortably near the NW. frontier of India. This vast territory, which covers an area more than twice as large as Europe, and embraces one-sixth of the land-surface of the globe, has a population estimated at about 140,000,000, belonging to a great variety of kinds, tribes, and tongues. In a slightly more restricted sense the name belongs also to the principal member of the federation, with about 93 per cent. of the total area. The other members are Ukraine, White Russia, Transcaucasia (itself a federation), Turkmenistan, and Uzbekistan. Within these many areas have been granted autonomy, some of them with the name of republic. The Russian dominions in America (Alaska) were sold to the United States in 1867 for \$7,200,000. The area

of European Russia was diminished in 1918 by the setting up of independent republics in Poland, Lithuania, Lettland, Esthonia (see the articles on these), and by the union of Bessarabia (which Russia claims as Ukrainian) with Rumania in 1920, by the cession of Petchenga to Finland (which had severed its connection with Russia), by Polish conquests in White Russia and Ukraine.

Constituent States.	Area in sq. m.	Population.
Russia.....	7,597,638	96,746,300
White Russia.....	42,888	4,294,500
Ukraine.....	165,854	27,663,900
Transcaucasia.....	74,499	5,421,000
Turkmenistan.....	181,478	914,600
Uzbekistan.....	124,292	4,802,600
	\$,166,744	139,753,900

The capital (since 1918) is Moscow.

In accordance with the principle of self-government of nationalities various regions have been erected into 'autonomous republics.' These are—in Russia proper: Bashkiristan, Tataristan, the Kirghiz or Cossack republic, Daghestan (Mountain republic), Crimea, Yakut republic, Karelia, Buriat and Mongol republic, German Volga republic; in Ukraine: the Moldavian republic, the Bulgarian republic; in Transcaucasia: Nakhichevan, Abkhazia, Adjara; in Uzbekistan: the Tajik republic. There are besides many regions with a minor share of autonomy.

The territory of the union, however different its separate parts as regards latitude and climate, is more homogeneous than it appears at first sight. It belongs to the great geographical division of Eurasia, which embodies both the plains of European Russia and the lowlands and plains that extend north of the two great plateaus of Asia—the high plateau of east Asia and the western plateau of Persia and Armenia (see ASIA). However, the Russians are rapidly passing the limits of the lowlands.

Seaboard, Islands.—Until the end of the 17th century Russia's seaboard was limited to the Arctic Ocean, and she had to wage a long series of wars before she secured a firm footing on the Baltic and the Black Sea. The latter, however, is an inland sea, the entrance to which still remains in the hands of a foreign power. The Arctic Ocean, which offers excellent fishing grounds in its western part, makes a deep indentation on the north coast of Russia—the White Sea (q.v.); but its gulfs, Kandalaksha, Onega, and Dwina, are ice-bound for nine months every year. Murmansk is open all the year. The only other port of any moment, Archangel, has now lost its former importance. Further east, Tehesskaya and Petchora bays are surrounded by frozen deserts. The Kara Sea, between the crescent-shaped island group of Novaya Zemlya and the coast of Siberia, is navigable for a few weeks only every year (see SIBERIA). The islands of Kolguev, Vaigatch, Novaya Zemlya, and the islands of Siberia—Nicholas II. Land (renamed Lenin Land), New Siberia, Medvezhiy, Wrangel, and others—are uninhabited, save that a settlement has been attempted in Wrangel Island. As to the Behring Sea and the Sea of Okhotsk, which contain good fishing and hunting grounds, their coasts are most inhospitable. The same is true of that part of the Japanese Sea which belongs to Russia. Its only great gulf, Peter the Great's, has in Vladivostok one of the finest roadsteads in the world; but this gulf is separated from the interior by wide tracts of uninhabited marshes and forests. Of the Baltic Sea, only the head of the Gulf of Finland now touches Russian territory. Nevertheless, four out of the five chief outlets of Russia—Leningrad (St Petersburg), Revel, Libau, and Riga—are situated on the Baltic Sea. Libau is the only

one which has its roadsteads open nearly all the year round; and Leningrad is the only one that remains Russian. The chief Russian island of the Gulf of Finland is Kotlin, with the fortress of Kronstadt.

The Black Sea acquires more and more importance every year. The fertile steppes of its littoral are being rapidly settled, and the centre of gravity of Russia's population is gradually shifting south. The Black Sea suffers, however, from a lack of good ports. Its great gulf, the Sea of Azov (whose ports are Taganrog and Rostov), is very shallow; the fine ports of the Crimea are too remote from the mainland; and the seaboard of Northern Caucasia is separated from the interior by a high chain of mountains. Odessa is the chief port of this sea; and it has no rival in Russia except Leningrad. Nikolaiev is poorly equipped. Sebastopol is a naval station. Batumi, the chief port of Transcaucasia, is of great importance for the export of petroleum.—The Caspian Sea, which receives the chief river of European Russia—the Volga—is an excellent medium of communication between the central Asian parts of the union and the Caucasus, as also for trade with Persia (to which the south coast belongs); but it has no outlet to the ocean, nor is there any probability of connecting it advantageously by canal with the Black Sea, because its level is 70 feet below the level of the ocean. The Caspian supplies Russia with considerable quantities of fish.

Orography.—The geographical features of the Caucasus, Siberia, and Turkestan being dealt with under those respective headings, the following remarks relate only to European Russia. The leading feature in its physical structure is a broad, flat swelling about 700 miles wide, with an average height of 800 feet, which crosses it from south-west to north-east and connects the elevated plains of middle Europe with the Urals. A belt of lowlands stretching from Poland to the White Sea fringes this central plateau on the north-west, separating it from the hilly tracts of Finland; while the plains of Bessarabia, Kherson, the Sea of Azov, and the lower Volga limit it on the south-east. The highest parts of the central plateau, hardly attaining 1000 to 1100 feet above the sea, lie along its north-western border—viz. the plateau of Minsk, the Valdai Hills, and the hilly tracts of the Sukhona and Vytchegda (upper Dvina). In middle Russia the same altitude is attained by the flat eminences of the plateau about Kursk and in the hills on the right bank of the Volga. In these places the country assumes a hilly aspect on account of the deep ravines which intersect it. The central plateau is, however, diversified by three depressions. One of these stretches south-east to north west up the broad valley of the Dnieper and thence beyond the Polish frontier to the Vistula; another follows the Don and joins the valley of the Oka; and the third extends from the north shore of the Caspian along the left bank of the Volga to the bend it makes at Samara. During the Postglacial period an elongated gulf of the Caspian Sea extended in that direction up the valleys of the Volga and the Kama as far as 55° N. lat. A fourth depression, about Nijni-Novgorod, bears traces of a great lake which was filled up during the same epoch.

The Urals, which separate the lowlands of European Russia from those of Siberia, are not the narrow chain of mountains running north and south which they appear to be on many maps. In the south they consist of a series of parallel ridges running south-west to north-east, their summits reaching 5395 feet in Yaman-tan, 5245 in Iremel, and 3598 in Taganai. Farther north, up to the latitude of 61°, they must be considered as a continuation

of the central plateau, bordered by several low ridges (north-west to south-east) which become more distinctly apparent between the Denezhkin-kamei (4841 feet) and the Toll-pass (5537 feet). They connect with a ridge that runs north-east into the Yamal peninsula. And finally, in the extreme north, a low ridge, the Pai-kho, crosses over into the island of Valgatch and the southern part of Novaya Zemlya. Thus the Urals exhibit the same great lines of upheaval—in a south-western and a north-eastern direction—which are characteristic features in the orographical structure of the great continent of Europe and Asia.

Rivers.—The chief rivers of Russia take their origin along the north-western border of the plateau, and some of them flow, broadly speaking, north-westwards, while the others, though describing great curves over the surface of the plateau, take a general direction towards the south-east. The Dvina, the Lovat (continued by the Volkhov and the Neva), and the two chief streams that reach the White Sea, the Onega and the North Dvina, are in the first case; while the Dnieper, the Don, and the Volga belong to the second category.—The tributaries of distant seas thus rising amidst the same marshes, on the same level of the plateau, and flowing in opposite directions, boats that have been brought up one river can easily be carried across a flat and marshy water-parting (*volok*) into the basin of another river and be floated towards another sea. The advantages that can be derived from such a disposition of the rivers are evident at a glance. At an early epoch of history it favoured the progress of the Russians from their cradle in Novgorod and Kiev towards the east; and later on it facilitated intercourse between distant parts of the territory upon which they had settled, and so maintained the unity of the separate parts. The whole making of Russia was closely dependent upon the courses of its rivers. Several of them have been improved for navigation and connected by canals, and many more could be, and certainly will be, improved. By means of three lines of canals and canalised rivers, which connect the upper tributaries of the Volga with the streams that flow into lakes Onega and Ladoga, the commercial mouth of the chief artery of Russia, the Volga, has been transferred from the Caspian to the Gulf of Finland—Leningrad being the chief port of the Volga basin. The upper Volga and the upper Kama are also connected by canals with the North Dvina, and the Dnieper with the Dvina (Duna), the Niemen, and the Vistula. Yet navigable rivers are unequally distributed over the territory; and the rivers of Russia, though exceeding in length those of western Europe, discharge a comparatively smaller volume of water. The rainfall all over Russia is small, and as part of it falls in the shape of snow, which is rapidly thawed in the spring, the rivers are flooded at that season and in early summer, and they grow shallow by the autumn. It has been estimated that one-third of the total volume of water discharged during the whole year by the rivers is carried during the spring and early summer floods. The amount of water discharged by the rivers also varies very much from year to year—a river which is navigable one year being often reduced next year to a small streamlet. During the winter navigation of course ceases.

Climate.—All over European Russia, with the exception of the south of the Crimea, and a narrow strip of land on the Black Sea, the climate is decidedly continental. A very cold winter, followed by a spring which sets in rapidly, and has therefore a charm hardly known to western Europe; a hot summer, the duration of which varies with the latitude; an autumn that is cooler than the

corresponding months of advanced spring; early frosts; and a small rainfall, chiefly during the summer and the autumn—such are the characteristics of the climate of Russia. The winter is cold everywhere. All over Russia the average temperature of January is below freezing-point. To find in Russia a winter as mild as at Königsberg (28° being the average of the three winter months) it is necessary to go as far south as Odessa. As for the southern Urals, they have a winter as cold as it is at Archangel. Even in south-west Russia the average temperature of March is a couple of degrees below freezing-point, while in the south-east it falls as low as 16° and 20°. All the rivers are frozen over in the first part of December, and they remain under ice for an average of from 100 days in the south to 150, and even 167, days in the north. At Astrakhan ice remains on the Volga for 90 days every year. On the other hand, in summer the temperature is so high all over Russia that it is only beyond the 60th degree of latitude that the average temperature of July is less than 62°. In middle Russia it rises to between 64° and 70°, and it reaches 78° at Astrakhan. The yearly temperature averages only 54° in the south and 32° in the north. The annual rainfall is very low as a rule. It averages from 14 inches in the east to 22 inches or more in the west. The moderating influence of the western winds is felt to some extent all over the country. But it decreases very rapidly as they make their way across the cold, dry plains. The strength of the wind, especially in winter, is greater as a rule, than in western Europe; by the end of winter blizzards often bury the railways under snow, and are very destructive to cattle.

Flora and Fauna.—With regard to its flora Russia may be subdivided into four regions. (a) The *tundras* of the Arctic littoral are devoid of tree vegetation. They are chiefly covered with mosses, lichens, and shrubs—the dwarf birch, the dwarf willow, and so forth, with the addition of a few herbaceous plants in the drier and more sheltered places, wherever sufficient humus has accumulated. (b) The *forest-region* covers the whole of northern and middle Russia from the *tundras* to the Steppes, and must be subdivided into two parts, the forest-region proper and the intermediate region of prairies dotted with forests. The forest-region has again two distinct parts—that of the coniferous forests, which cover nearly the whole of northern Russia beyond the upper and middle Volga, and the oak region. The forests of the latter class consist of various deciduous trees (birch, aspen, oak, &c., as well as the ash and the hornbeam farther south), and appear as islands in the midst of cornfields and rich meadows, adorned with a great variety of flowers. The flowering plants are those of middle Europe. The beech, so characteristic of the western European flora, does not extend farther than the frontiers of Poland (it reappears in the south-west and in the Crimea); and in the north-east the botanist finds an admixture of species of Siberian extraction. A line drawn from Kiev to the sources of the Ural would separate roughly the forest-region from an intermediate region—the *Ante-Steppe*—in which the forests and the Steppes struggle with alternating success for every square mile of land; and another line, almost parallel to the above, drawn from Ekaterinoslav to Uralsk, may be taken as the limit of (c) the *Steppes*. These are immense plains covered with grass, but devoid of forests, very much like the *prairies* of America and the *pushtas* of Hungary. A great variety of plants characteristic of the Steppes are found in this belt in addition to the species that occur in middle Russia; while towards the Caspian a great number

of species characteristic of the Aral-Caspian deserts penetrate into European Russia. Finally, (d) the flora of the Mediterranean region occupies a narrow strip along the southern coast of the Crimea. Many of its flowering plants are quite unknown in the continental part of Russia.—The fauna of European Russia is very much like that of middle Europe, the chief difference being the occurrence of a few species, now extinct elsewhere in Europe but still inhabiting Asia, and in the south-east there are several species characteristic of central Asia. Wolves and bears are common in the north. The reindeer is still met with in one or two regions; the wild boar is limited to one district; the elk, the lynx, the glutton, the beaver, once common, are now very scarce.

The Lake-region.—A depression, the surface of which is less than 300 feet above sea-level, stretches between the central plateau and the hills of Finland and Olonets, from the Gulf of Riga through the Baltic States and Russia to Lake Onega, and is continued over a low water-shed towards the lowlands of Archangel. It has but recently emerged from the Postglacial sea, and is dotted with marshes and numberless lakes, of which Peipus (on the Esthonian border), Ilmei, Ladoga, Onega, and Vodlo are among the largest. Low, flat ridges, partly carved out of the rocks by the ice-sheet, and partly of moraine origin, intersect the country; the soil is unfertile, and mostly too wet for the successful prosecution of either agriculture or cattle-breeding. The marshy forests are mostly thickets of thin firs, birches, aspens, &c., of poor aspect. Numberless rivers connect the lakes with one another, or with the Gulf of Finland.

The plains of the lower Dvina and Mezei, which fringe the White Sea and the Arctic Ocean, bear the same character, the vegetation being, of course, even poorer than in the lake-region; while the coasts of the ocean are fringed by a belt of treeless *tundras*. To the north-west of the lake-region lies the peninsula of Kola, a marshy tableland, inhabited by only a few Lapps. And in the far north-east, between the Timansky ridge and the Urals, there is an immense territory—the *Petchora region*—covered with *tundras* in the north, and with impenetrable forests in the south; it is thinly inhabited by a handful of Russians settled along the courses of the rivers, and by Samoyedes and Zyrian hunters in the forests.

The *central plateau* contains the most populous agricultural and industrial parts of European Russia. Its physical aspects vary, however, a good deal in the different parts.

White Russia.—The territory watered by the upper Dnieper and its tributaries is one of the poorest regions of Russia. Much of its area is covered with marshes; and the soil that is not under water consists chiefly of peat-bogs, hard boulder-clay, and sands. The depression between the Pripyet and the Berezina called *Polyessie* ('the woods'), also spoken of as the Rokitno swamp, is for hundreds of miles an almost uninterrupted marshy forest, flooded with water in the spring. White Russians are the predominant element in the population of the country, but the western part has been annexed by Poland.

Little Russia, or Ukraine.—Little Russia is one of the richest and most populous parts of Russia. The soil is mostly a rich black earth, and assumes farther south the aspect of fine grassy steppes, or prairies, yielding rich crops of wheat. The climate of this region is relatively mild, especially in Volhynia (of which the west is in Polish hands), and gardening is extensively carried on. Cattle-breeding and especially sheep-breeding are prosecuted on a grand scale on the prairies. In the north of the territory beet is much cultivated for sugar.

Kiev is one of the chief industrial centres of Russia, and woollen cloth mills have rapidly spread in Podolia. The population is chiefly Little Russian, with a considerable number of Moldavians in Podolia, where a Moldavian republic has been set up.

Middle Russia.—The provinces of Tver, Moscow, Vladimir, Smolensk, Orel, Tula, Kaluga, Kursk, Rязань, Tambov, Penza, part of Voronezh, southern Yaroslavl, and Ulianov (Simbirsk) are comprised under the general name of Middle Russia. Except on its outskirts, this region presents everywhere the same aspects, wide undulating plains covered with cornfields and dotted with small deciduous forests. The soil is of very moderate fertility in the north, where it chiefly consists of boulder-clay; but towards the south it becomes very fertile in the black earth belt. The population is thoroughly Great Russian, with but a small admixture of White Russians and Little Russians in the west, and of Tatars and Finnish stocks, mostly russified, towards the east. They live in large villages, pursue agriculture in summer, and carry on a great variety of domestic trades in the winter. Moscow and the surrounding governments are the busiest industrial region of Russia.

Upper Volga and Kama.—Farther north-east the country is more elevated, but less effectively drained; and vast forests stretch from the upper Volga to the Urals. The governments of Kostroma, Vologda, and Vyatka, those parts of Nijni-Novgorod that lie on the left bank of the Volga, the Mari territory, and the Tatar republic, belong to this domain. Its population is thin. The villages and towns are separated by wide uninhabited tracts, and intercommunication is difficult, the Kama and its tributaries being the principal highways to middle Russia. The former government of Perm (which included the mining districts on the Asiatic slope of the Urals, and now forms part of the Ural Area of Siberia) and the northern part of the Bashkir republic are the chief centres for the iron industry.

The Middle Volga Country belongs to a great extent to the steppe region of south Russia. The forests, which are still extensive in the Tatar republic and in the hilly tracts of the Urals, gradually thin away, till towards the south the territory becomes a wide prairie, which often suffers from want of rain. The dry, hot winds of central Asia make their influence felt. The population, mostly Great Russian, contains a large percentage of Turkish and Finnish race, and, in the German Volga republic, of Germans.

The Steppe-region occupies a belt more than 200 miles wide along the littoral of the Black Sea and the Sea of Azov, and extends eastwards through the region of the lower Volga and Ural till it meets the steppes of central Asia. As far as the eye can reach there are gently undulating plains, clothed with rich grass, and entirely destitute of trees; yet in the bottoms of the deep ravines, concealed by the undulations of the surface of the steppes, there grow a variety of trees and shrubs, as willows, wild cherries, wild apricots, and so forth. The whole is coated with a thick layer of fertile 'black earth.' For many centuries the Russians coveted these fertile grounds, but it was not until the 18th century that they actually took possession of them; they have since rapidly covered them with their villages. In order to people Bessarabia without depriving the Russian landowners of their serfs, several races of foreigners, as Moldavians, Wallachians (Vlachs), Serbs, Greeks, Germans, and even Scotsmen, were freely invited to settle there. Russia still claims Bessarabia though Rumania now holds it.

The same steppe-land extends into the peninsula

of the Crimea, but there the soil is no longer black earth, but a clay impregnated with salt. Its extreme dryness prevents it from being utilised for agriculture. A narrow ridge of mountains, the Yaila, reaching 4000 to 5100 feet in their highest summits, rises on the south-east coast of the Crimea. Its southern slope is the most beautiful corner of Russia, owing to its Mediterranean climate and Mediterranean flora. Farther east the *Caspian Steppes*, in respect both of their physical features and of their population, form an intermediate link between Europe and Asia. They only emerged from the sea in quite recent geological times, and their surface, perfectly flat, still lies below sea-level for a distance of more than 150 miles from the shores of the Caspian. The small streams which cross them mostly dry up through evaporation, and seldom reach the sea. The Volga and the Ural divide into numerous branches before entering the Caspian Sea, and afford the richest fishing grounds in the world. Numerous salt lakes, whence Russia gets her supply of salt, are scattered over the steppes. The population consists to a great extent of Tatars, Kirghizes, and Kalmycks. Cattle-breeding is the industry mostly followed; and fishing is a valuable source of income.

Ethnography.—The population of Russia embraces a great variety of nationalities; but the Russians, comprising the Velikorusses or Great Russians, the Malorusses or Little Russians, and the Byelorusses or White Russians, are by a long way the predominant people. None of the three is, of course, a pure race. The Great Russians, who invaded a territory occupied by Finnish tribes, ended by assimilating them. The Little Russians underwent a mixture with Turkish tribes, and the White Russians with Lithuanians. However, the Russians mostly russified those they came in contact with. The Great Russians inhabit middle Russia in a compact mass, and even in east and north Russia they constitute from two-thirds to three-fourths of the population. The Little Russians are settled in a solid body in Little Russia, which contains but a slight admixture of other peoples—chiefly in the borderlands. The White Russians also dwell in a compact mass in the west, but they are more mixed with Poles, Jews, and Little Russians. Other Slavs—Serbs, Bulgarians, and Bohemians—exist in small colonies in Kherson. Armenians, Kurds, and Persians and other Iranians live chiefly in Caucasasia. The Caucasus (q.v.) is inhabited by a great variety of races and tribes. Jews are very numerous in the towns of west Russia. Nearly three-fourths of the Russian Jews are artisans or factory-workers, while the Jews settled on the land in Kherson have proved themselves good agriculturists. The Finnish stems include the Finns and the Karelians; the Estonians, the Western Finns in the Baltic; the Lapps and the Samoyedes in the far north; and the Volga Finns and the Ugrians in European Russia and in Siberia. The Eastern Finns are being rapidly absorbed by the Russians; but the Western Finns still maintain and warmly foster their nationality. The Turko Tatars—i.e. Tatars, Bashkirs, Kirghizes, &c.—are mere feeble remnants of the tribes who once conquered Russia. The Mongol race is represented by Kalmycks in Russia and central Asia, as well as by Buriats in Siberia; while the Manchurian tribes of the Tunguses, Gols, &c., and the Hyperboreans also form a small part of the population of Siberia (q.v.). Of west Europeans the Germans are the most numerous. They have prosperous colonies in south Russia, notably in the German Volga Republic; and in the chief towns there are numbers of Germans, artisans and merchants. There are, besides, Rumanians in south-west Russia.

Religion.—The great bulk of the Russians—excepting a few White Russians professing the Union—belong to the Græco-Russian Church, officially styled the Orthodox-Catholic Church, or to one of its numberless sects (*raskol*). The church was disestablished in 1917. Its property has been taken over by the state, which is said to take much better care of the works of art that thus came into its hands than the ecclesiastical authorities had done. The state grants a free lease of church buildings to members of the congregations. Religion may not be taught in classes but may be at home. There is much hostility to the church, and to religion in general among those in power. Nearly all the Jews obey the injunctions of the Talmud, with the exception of a few Karaites in the Crimea and west Russia. Islam has a large number of followers—all the Turko-Tatars, Bashkirs, and Kirghizes. Buddhism has its followers in the Kalmuks and the Buriats. Shamanism is the religion of most of the natives of Siberia, as well as of the nominally Christian Mordvins, Votyaks, Tchevaches, and the nominally Moslem Mescheryaks, and (partly) the Kirghizes. The Voguls, the Samoyedes, and other inhabitants of the far north are fetish worshippers. For the relations of the Russian Church with the rest of the Orthodox Eastern Church, see GREEK CHURCH.

The Raskolniks.—A most important part is played in the popular life of Russia by the numerous sects of *raskolniks*, to which nearly one-third, or more, of the so-called Orthodox Russians belong. New sects arise every year, and even among the Little Russians, who used so piously to preserve their traditional religion in the face of the Catholic propaganda, a nonconformist movement sprang and spread with wonderful rapidity under the name of the 'Stunda.'

The Russian *raskolniks* may be classed under three divisions, all equally numerous: the 'Popovtsy' (who have priests), the 'Bezpopovtsy' (who have none), and the 'Dukhobnyie Khristiane' (spiritualist Christians). The first named object to the revision of the sacred books which was accomplished under the patriarch Nikon (see *History*, below), as well as to the hierarchy of the Russian Church. They are hostile to all kinds of 'novelties,' maintain the patriarchal family arrangement, and get their priests either from abroad or from priests who have left the Orthodox Græco-Russian Church. A branch of the Popovtsy, the 'Yedinoverytsy,' recognise Russian priests on condition of their keeping to the unrevised books.

The Bezpopovtsy repudiate the Orthodox ritual and the sacraments, and have no priests. Any man or woman may conduct divine service if recognised by the community. The state is considered by them as an entire invention of the Antichrist. Yet very few amongst them really break off all connection with the state, and lead a life of outcasts, as the 'Stranniki' (the Errants) do.

The 'Spiritualists' comprise very many sects, all more or less imbued with either Protestant or rationalist teachings, as well as with communist tendencies more or less carried into practice. The chief of them are the 'Dukhoborsy' (warriors of the spirit), the 'Molokany' (Milk-eaters), both a kind of Baptists—the former have a strong leaven of practical communism—and the 'Stundists,' who are much under Protestant influence. The 'Khlysty,' or Flagellants, and the 'Skakuny,' or Shakers, belong to the same division. The Skoptsy (Castrati) have isolated adherents everywhere.

Government.—The political organisation of Russia under the empire was a very heterogeneous structure. It had at bottom a very great deal of self-

government, based upon quite democratic principles. But above this stood the imperial authority, represented by an army of officials, whose powers, down to those of the very humblest rural policeman, were extremely vague and very extensive; and these officials were constantly interfering with the local self-government, and paralysing it, without, however, being able either to destroy it or to reduce it entirely into submission to the central authority. The empire was till 1906 an absolute and hereditary monarchy, the final decision in all legislative, executive, and judicial questions resting with the emperor, who nominated the ministers and whose will was law. The revolution of 1905-6 was on the whole a failure. It left Russia, as the *Almanac de Gotha* put it, a constitutional monarchy under an autocrat tsar.

Even under the empire the peasants (the great majority of the nation) had some experience of self-government and communism. The land being held in common throughout Great Russia and Siberia, it was the *mir* that periodically distributed the land into allotments and then assigned them to the several households according to their respective working capacities. The *mir* could also open schools, support a midwife or a doctor, and undertake all kinds of works of public utility. It always elected its own executive, the *starosta* (elder), the tax-collector, and so on. This institution of the *mir* forms the basis of village life among all Great Russians, and traces of it are found among the Little Russians as well. All investigators of the *mir* are unanimous in recognising that it shows a wonderful elasticity in accommodating itself to new conditions. Stolypin's changes went far to undermine it; and even the communist government put a restriction on the redistribution of land. The administration of the economic affairs of the district and the province in European Russia was in 1866 committed to the district and provincial assemblies, or *zemstvos*.

Under the Constitution of 1923 (ratified 1924) the supreme organ of authority in the Union is the Congress of Soviets, and in the intervals between Congresses the Central Executive Committee of the Union, consisting of the Council of the Union and the Council of Nationalities. Delegates to the Congress are elected by town soviets (1 to every 25,000 electors), and provincial congresses (1 to 125,000) or where there are no provinces the state congress. The Council of the Union, elected by the Congress of Soviets, represents the various states in proportion to population. The Council of Nationalities represents the various autonomous republics and regions set up within the states. Between sessions of the Central Executive Committee the supreme authority, legislative, executive, and administrative, is its Praesidium, or permanent committee. The Central Executive Committee also chooses a subordinate authority, the Council of People's Commissaries, consisting of a president, vice-presidents, and People's Commissaries, or heads of ministerial departments (as foreign affairs, war and marine, foreign trade, transport, &c.). Each of the federal states has a constitution similar to that of the Union, with its Congress of Soviets, Central Executive Committee, and People's Commissaries. Each state has the right to secede, and provision is made for the adhesion of new states. Turkmenistan and Uzbekistan have thus been formed and joined the Union in 1925. The soviet system, ramifying through the whole public life of Russia, is explained in the article SOCIALISM. The franchise extends generally to citizens, male or female, 18 years of age and upwards, who earn their livelihood by productive labour, and to soldiers and sailors of the Red army and navy. Those who exploit labour of others

(with certain exceptions), priests and monks, the police and secret service agents of the old régime, and certain others are disfranchised.

Army and Navy.—By the law of 1925, service in the Red army or navy is compulsory for proletarians between the ages of nineteen and forty. Others serve in working battalions or pay a tax. The Red army was reduced from 5,300,000 in 1920 to 563,000 in 1925. The navy awaits reconstruction.

Judicial System.—Trial by jury was introduced in 1864, proceedings in the law-courts made public, and corporal punishment abolished; the preliminary inquiry was still secret. Certain political offences were brought before a special department of the senate, but the greater number were disposed of by the department of State Police in the ministry of the Interior, suspect persons being transported to Siberia without bringing them to trial before a court. The prisons of Russia were extremely overcrowded, and on the whole in a very deplorable condition. Every year from 15,000 to 20,000 offenders were transported to Siberia, one-half by decisions of the courts, and the remainder by order of the administration (see *SIBERIA*). Capital punishment for common-law offences was abolished about 1770; but death continued to be inflicted for political offences. A new system has been set up since the revolution, with People's Judges in the primary courts, assisted in the People's Courts by assessors. Over these are provincial and supreme courts. The Supreme Court of the Union deals with the interpretation of general legislation, questions between the republics, and the like. The Communists introduced a new prison system aiming at education, not retribution, setting prisoners to work at their own trades at trade union rates of wages. Nevertheless serious abuses continued to be reported.

Education.—In 1900 only one-fifth of the army recruits could read and write. According to the 1920 census 46·5 per cent. of the population were literate (61·7 per cent. of males, 33·6 of females). Matters have been mended in great measure by the strenuous work of the government and the local Soviets. The People's Commissariat for Education for each republic has charge of the whole system, including Unified Labour Schools, adult schools, universities, special schools, museums, monuments, theatres, learned institutions, &c. Many new universities have been founded. Palaces have generally been converted into museums, often with their former owners as curators; and the art treasures of the church are under competent care.

Agriculture.—Agriculture is the chief occupation of the people of Russia; only in central Russia (Moscow, Vladimir, Nijni) does industry take the lead. A line drawn across European Russia, from Kiev to Nijni-Novgorod and Vyatka, will divide the country into two parts, of which the south-eastern has normally a surplus of wheat and rye and exports them, while the other has to import both. More than one-half of European Russia thus produces less wheat and rye than is needed for home consumption. If all the wheat and rye produced by Russia in an average year were consumed within the country itself, the annual consumption throughout the country altogether would be about the same as in France. This disposes at once of the theory that Russia may be regarded as the granary of Europe. Moreover, the crops of Russia are subject to great fluctuations, and bad years recur, as in India, at intervals of from ten to twelve years. The principal cereal is rye, the staple food of the people. The other cereals are wheat, oats, barley, buckwheat, and millet. Flax and hemp are extensively grown in the west, the sugar-beet is grown in the south and south-west, and sun-

flower, potatoes, and tobacco are also largely cultivated. The vine is widely grown on the Black Sea littoral and in Caucasasia, and some of the wine produced is excellent.

Mining.—Russia is very rich in all kinds of minerals. Gold is obtained in Siberia, the Ural Mountains, and the Caucasus. Silver and lead are obtained in Siberia, the Urals, the Caucasus, and the Kirghiz Steppes; platinum in the Urals. Iron ores are found in profusion both in Asiatic and in European Russia (Urals, central Russia, south Russia); zinc, cobalt, and manganese ore in Caucasasia; manganese also in south Russia and the Urals. Salt is obtained from the salt-lakes of Asia and south Russia. Russia has excellent coal-basins, especially in the Don region, but the immense forests and the facilities for shipping firewood on the rivers kept back the development of coal-mining. The exceedingly rich wells of Baku and Grozny supply petroleum. Asbestos, mica, mercury, and copper are other important minerals.

Manufactures and Petty Trades.—The manufacturing industry of Russia has grown up since the abolition of serfdom. All industrial and commercial enterprise was nationalised in June 1918. A method of leasing to co-operative societies, companies and individuals was adopted in 1921; and in 1923 a system of state trusts and syndicates was set up. The chief industrial centres are Moscow and the surrounding governments, and St Petersburg. The woollen trade is firmly rooted in the south. The production of *vodka*, the national spirit, prohibited during the Great War, has been resumed owing to revenue needs. There are many sugar-mills and soap and tallow factories.

The domestic industries, which are carried on by the peasants of central Russia contemporaneously with agriculture, are of much greater importance in Russia comparatively than they are in western Europe, but have fallen off. The greatest conceivable variety of products are thus manufactured in the villages. Co-operation, which enters into the essence of Russian peasant life—the *artel*, or co-operative productive or consuming association being constituted by Russian peasants and factory-workers for every possible purpose—finds a wide field for application among the domestic crafts.

Commerce.—Foreign trade, at a stand-still after the Great War, began to revive in 1921. Trade agreements were made, resuming commercial intercourse with several countries. Concessions to foreign capitalists were legalised. Normally the exports of Russia to foreign countries consist principally of corn and flour, various articles of food (butter, eggs, &c.), flax, timber, oil-seeds and oil-cake, raw wool, and petroleum. The imports are chiefly of raw materials, foodstuffs, tea, machinery, iron and steel goods. The inland trade of Russia was at first restricted by the Soviet government to exchange of commodities; but in this also compromise was found necessary. The great fairs (at Nijni-Novgorod, Kharkov, Irbit, &c.) are still of immense importance. They were discontinued during the troubles, but were resumed in 1922-23.

Communications.—The importance of the Russian rivers for traffic has already been mentioned. It is computed that European Russia has 20,670 miles and Asiatic 86,422 miles of rivers, lakes, and canals navigable by steamers, besides waterways suitable for smaller craft and rafts. Railways were out during the Great War and the terror, but some 45,000 miles are in use. The Siberian railway to Vladivostok and Port Arthur was completed in September 1904 by the opening of the Baikal section; and the Orenburg-Tashkend line was finished in 1905.

Architecture.—Russian architecture is directly descended from Byzantine (q.v.), but modified by native and Asiatic influences. The first church-building tears, such as Vladimir (981-1015), employed Greek architects; but their churches were mainly of wood and have disappeared. The usual Russian church has a central dome, surrounded by four (or more) smaller cupolas, whose form has been, under Tatar influence, changed to the onion-shape that appears in Mongol-Indian mosques on the Ganges. In the famous cathedral of St Basil, of which an illustration is given at MOSCOW, the central tower is surrounded by eight smaller ones, crowned by various bizarre cupolas, and painted with the most brilliant colours. This church was built by Ivan the Terrible about 1554. After the time of Peter the Great the native type gave way to reproductions—often bad—of various classical models; the architecture of St Petersburg is characterised at RENAISSANCE.

History.—The Slavs were not the primitive inhabitants of the plains of eastern Europe; in the first centuries of our era their abodes were on the Danube, the Elbe, and the south shore of the Baltic Sea, and they entered what is now Russia from the west. The southern Slavonians took possession of the upper Bug, Dniester, and Dnieper, while the northern occupied the lake-region of Pskov and Novgorod. The date of that immigration is not known, but it is certain that in the 9th century their small tribes occupied—besides part of what is now Poland—a territory stretching north and south from lakes Peipus and Ilmen to the mouth of the Dniester. Various Finnish tribes were then living in Finland, and the basins of the Dwina, Petchora, and upper Volga; the space between the Duna and the Vistula was inhabited by the Lithuanians; while several Finno-Turkish tribes, mostly nomads, had taken possession of the southern slopes of the central plateau: the Bulgars were at Kazan; the Mordvins, the Mescheryaks, the Tchuvasches, and the Tcheremisses on the middle Volga; and the Khazars in the southern Steppes. Finally, the Turkish stems of the Polovtays, the Petchenegs, and the Turks camped in the Caspian Steppes to the east of the Volga. Already at that time the Slavs were agriculturists, and their country was dotted with numerous small forts. Like all primitive inhabitants of Europe, they were organised in 'gentes'—the family once having been matriarchal. The land was held in common by each clan and tribe, and the common affairs were decided at folkmoets, or assemblies of the clan, the tribe, or the 'land.' Cæsar and Tacitus found the same organisation among the ancient Germans.

The territory of the eastern Slavs was the great highway from Scandinavia to Greece; and caravans of Scandinavian merchants followed the route from Novgorod to Kiev on their frequent journeys to Constantinople. The same route was followed by the Norman warriors (Vikingar, Varyagues, Varangians), who, reinforced by Slav adventurers, used to engage in the service of the Greek emperors. The Greeks used to call them Rosses or Russes, but it remains uncertain whether the name was borrowed from some locality in Scandinavia (Ros, Roslagen; Ruotsi = Sweden), or what seems more probable if Arab testimony is taken into account, from a territory on the Dnieper. It is more than probable that from a remote antiquity the Slavs used to apply to leaders of such military bands for protection, and the oldest Russian chronicle, known as Nestor's (it was probably compiled from older chronicles and epic traditions about 1115, by the Kiev monk Sylvester), says that the folkmoets of the northern Slavs, after having sent away in 859 the Varangians to whom they paid a tribute, sum-

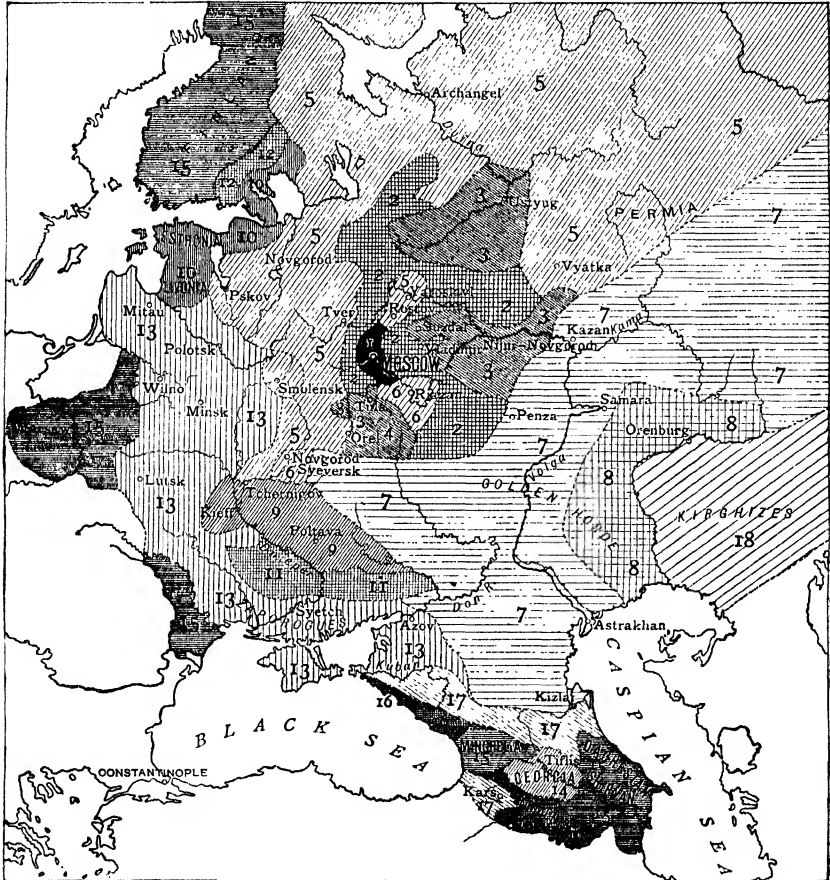

moned again the Varangian rulers in 862 'from beyond the sea,' 'to command and judge them according to law.' The first historians of Russia, who used to interpret facts of a remote past according to modern conceptions, were disposed to regard the Varangian dukes as a sort of modern kings, and spared no effort in tracing a 'Rurik dynasty' down to our own times. But the supposed kings were simply military chiefs, to whom the military defence of the cities was entrusted, like the *podestà* of the Italian cities in the 15th century.

Three brothers, Rurik, Sineus, and Truvor, were thus invited, according to tradition, and they settled respectively in Ladoga, Byelozersk, and Izborsk—i.e. on the borders of a territory which had to be defended against the Finns and the Lithuanians. They and their successors built new forts, and took part in wars, the description of which in Nestor's chronicle has all the characters of an epic poem. Rurik's brother, Oleg, is said to have imposed his authority upon Kiev and Smolensk; he, as well as Rurik's son Igor, made campaigns against Constantinople; and Oleg's widow, Olga, who ruled after his death, was baptised in the Greek capital. Wars were waged, under Svyatoslav's leadership, against the Khazars and the Greeks. The Russians conquered Bulgaria, took possession of all its fortresses, and nearly captured Constantinople. The campaign (fully described by Byzantine historians) ended, however, in a disaster. The times of the 'Sunny Vladimir' (980-1015) are the heroic epoch of early Russian history, and the feats and feasts of Vladimir and his *druzhina* ('war companions') have been handed down through ages in legend and song; while his conversion to Christianity made him the hero of the annals written by monks. He and his *druzhina* were baptised at Kiev in 988, and the people of Kiev soon followed him. The first half of the 11th century, during which Yaroslav the Wise was grand prince at Kiev, while his brothers and nephews ruled at Novgorod, Polotsk, Murom, Vladimir in Volhynia, and even Tmutarak in north Caucasia, was the most brilliant time for Kiev. The 'mother of the Russian towns' grew to be a populous city, visited by numerous caravans of merchants, and Adam of Bremen described it as 'a rival to the supremacy of Constantinople.' The great cathedral of St Sophia was built at that time, as also many other churches. Schools were opened, and the first written Russian law—the 'Russkaya Pravda,' or, at least, its essential parts—was compiled. It corresponds to the *leges barbarorum* of the ancient Germans and Scandinavians. By the end of his life Yaroslav was ruling over most of the Russian towns, and his daughters were married, one to the king of Poland, another to Harold in Norway, a third to Henry I. in France, and a fourth to the king of Hungary. He died in 1054.

The next two centuries of Russian history correspond to the feudal period of western Europe. In the annals they appear as an uninterrupted succession of petty wars between the descendants of Yaroslav for the right of ruling in this or that city, or for the supremacy at Kiev. But modern research has disclosed the real character of the epoch. The Russians at that time were steadily extending their territory towards the east: they colonised the Oka, the Don, and the Finnish territories in the north-east. Between the numerous clans and territories into which they were divided there were no exterior bonds of unity save the unity of language and religion, and the common idea that no princes must be taken by any Russian territory except from among the descendants of Yaroslav. The natural centres of the territory were its fortified towns, which offered a refuge to the population in case of need. In each town the folk-

moot remained supreme; it decided upon war and peace; it invited a prince to defend the territory, and the prince, before being recognised as such, had to sign a covenant (*ryad*), and to take the engagement to rule according to law. He was bound to keep a band of warriors (*druzhina*) to protect the territory, and was entitled to levy for that purpose a tribute as well as the usual judicial fines: the disputes among the citizens being settled by twelve jurors (six for the defendant and six for the

plaintiff), the prince or his deputy had to pronounce the sentence and to levy the fine when the parties applied before the prince's court instead of the folkmoot. The cities usually were divided into sections and 'streets,' corresponding to the trade and artisans' guilds, and each of them had its own self-government; it elected its priests and functionaries, while the folkmoot of the whole city elected the *posadnik* or mayor, the *tyisiat'skiy* or commander of the militia, and the bishop.

Historical Map of Russia:

- | | |
|--|-------------------------------------|
| 1. Principality of Moscow under Daniel, 1303. | 10. Acquisitions of Peter I., 1725. |

| 9. " Alexei Mikhailovich, 1676. | 17. " Alexander II., 1881. |
| | 18. " the period 1780-1845. |

The fortifications of the cities were mostly built out of the wealth accumulated by the cathedral church, which was the exchequer of the city. The guilds of the merchants in larger trading cities, like Novgorod and Pskov, used to carry on trade in

the name, and, at the outset, for the benefit of the whole city. The city—not the individual—sent out its caravans and boats, and it also used to send out parties of young men into the lands of the Finnish tribes to carry on trade, to levy tribute,

and to colonise them. In this way Novgorod conquered the north-east of Russia, and founded there its daughter-republics of Vyatka, Dvina, and Vologda; and later on its men crossed the Urals to trade with Siberia. Kiev was recognised as the eldest of the cities, and the eldest of the kin of the princes had to rule at Kiev. But this unwritten agreement was not always obeyed, and consequently numberless petty wars took place between the princes. The country, however, took no part in these wars, with the exception of a few isolated cases always specified in the annals. In each territory there was the chief city (*gorod*), and the subordinate ones (*prigorod*), but no traces of submission of the latter to the former can be discovered in the documents of the times, the annals simply mentioning that the *prigorods* take the same decisions as the *gorod*. The soil belonged to the freemen who cultivated it; but slavery existed, and there was some trade in slaves, chiefly prisoners of war. A free man who entered into any one's service without agreement and remained in a servant's position for more than one year was also considered *kholop* or slave, as well as he who sold himself into slavery under the pressure of necessity. Trade prospered at that time, especially at Kiev, which was the great storehouse for trade with Greece and Asia, and Novgorod (which later on joined the Hansatic League) for the trade with Germany and Scandinavia. Pskov, Smolensk, and Polotsk also were important centres of commerce.

During the 10th, 11th, and 12th centuries Russia was thus covered with a number of free democratic republics. But the Greek Church already worked hard at introducing into Russian life the conception of the state and the authority of the monarch. Instead of the common-law view of justice as amended by the offender for the wrongs he has done to the individual or the community, the church introduced the Roman conception of justice as established by the state, and with it the idea of cruel corporal and capital punishments. At the same time it spread education and developed the taste for reading, and its monasteries were centres of further colonisation. But it also introduced the Byzantine ideas of asceticism and submission, and subsequently its influence, reinforced by that of the Mongols and the Tatars, contributed to give to woman a subordinate position quite contrary to the spirit of the Slav laws. And finally a new power grew up during the same centuries—viz. that of the *boyars* or *boiars*. Formerly they simply were the chief warriors and councillors of the *druzhina*; but later on, as some of them grew wealthier through trade and war, they acquired more and more importance in the cities as well as in the country. Thither they attracted peasants to settle on the free lands, and gradually reduced them to the condition of tenants. Such was the state of Russian society during the *udelnnyi* or feudal period before the Mongol invasion. Of all the princes who ruled at Kiev during that period Vladimir Monomachas (1113-25) deserves special mention as a ruler whose paternal authority was recognised by most Russian princes, whom he succeeded in bringing together for the defence of the territory against the Polovtsy. With him really ended the supremacy of Kiev, south-west Russia becoming more and more the prey of its nomad neighbours, as well as of its western neighbours, the princes of Volhynia and Galicia.

Owing to the gradual colonisation of the basin of the Oka and the upper Volga, a new Russian territory had grown in importance in the meantime. Suzdal and Rostov were its chief centres. It differed from south-west Russia in many respects: its inhabitants were Great Russians—a

hard-working race, less poetical and less gifted, but more active than their southern brethren. Besides, a good many of its inhabitants were peasants settled on the lands of the *boyars*—country-people, not accustomed to the folk-modes of old; and the cities themselves, being of recent creation—like Vladimir and, later on, Moscow—had not those traditions of independence which characterised Kiev or Novgorod. It was therefore easier for the authority of the prince to develop in the north-east, under the guidance of the church and the boyars, without being interfered with by the *vetche*. The Suzdal prince, Andrei Bogolubskiy (1157-74), was the first representative of that policy. He and his churchly advisers founded a new town, Vladimir, on the Klazma, a tributary of the Oka, and sanctified it by transporting thither from Kiev an icon of the Virgin, which had come from Constantinople, and was reputed to have been painted by St. Luke. He invited many Kiev boyars to settle in the land of Suzdal, and finally he undertook to strike the last blow at the supremacy of Kiev. He induced the land of Suzdal to levy an army, which took Kiev in 1169, plundered and burned it, massacred numbers of its inhabitants, and carried others away into slavery. The supremacy of Kiev was thus destroyed, and the land of Suzdal became the *Île de France* of Russia—the nucleus of the future Russian state. Andrei was killed by his own boyars; but the Suzdal land continued to grow and to enjoy prosperity during the next fifty years; economical, educational, and literary progress were marked, and the Russian territory extended farther eastwards. A rival was given to Novgorod in Nijui-Novgorod, at the junction of the Oka with the Volga. But in the 13th century a great calamity visited Russia; a Mongol invasion suddenly put a stop to the development of the country and threw it into a totally new direction.

For several centuries past the rapid desiccation of central Asia (see ASIA) had been compelling the inhabitants of the high plateau to migrate into the lowlands, and thence westwards towards Europe. Under this pressure of Asia upon Europe the Ugrians, who inhabited the Urals, moved over the south Russian steppes to Hungary; and the Polovtsy, the Petchenegs, and other tribes were making in succession their raids upon south-west Russia. Now it was the turn of the nomads, who inhabited the very heart of Asia, and whom Genghis Khan (q.v.) had united into a great confederation, to enter Europe. They already had conquered Manchuria, part of north China, Turkistan, and Bokhara, and devastated the encampments of the Polovtsy. The Polovtsy applied for aid to the Russians, and their united forces met the invaders on the Kalka River (a tributary of the Don) in 1224. The Mongols and Tatars were completely victorious, but retreated and did not return to Russia till after thirteen years. In 1238 the hordes of Batu-khan invaded the whole of east and central Russia. Ryazan, Rostov, Yaroslavl, Tver, and Torzhok were burned; only the marshes of Novgorod protected the north-western republic from the same fate. In 1239-40 they ravaged the south-west, destroying Tchernigov, Galicia, and Kiev, and entered Poland and Hungary. But, being checked in Moravia, and receiving at the same time the news of the Khan's death, Batu-khan returned to Asia, and built his palace at Sarai on the lower Volga. Thither the Russian princes had to go to pay tribute and receive their investiture by kissing the stirrup of the khan.

After having ravaged Russia the Mongols did not interfere much with her internal organisation. They respected the church; they left the peasants in possession of their lands, and the princes in

of their authority; but every prince had receive his investiture from the khan, and it was at the khan's court, sometimes on the banks of a tributary of the Amur, that intrigues for supremacy between the Russian princes were settled—sometimes through the assassination of the prince who was not rich enough to buy the support of the advisers of the khan. It was especially with Mongol aid, and often with Mongol armies, that the wealthy princes of Moscow succeeded in destroying the autonomy of the surrounding principalities, and imposed upon them their own yoke.

The taxes of Russia were originally farmed out by the khan to oriental merchants; but to avoid popular revolts, the princes undertook to collect them with the aid of the Tatars. The courts of the Russian princes, who surrounded themselves with Tatar and Mongol advisers, took an oriental character. The industrial, artistic, and literary development of Russia was totally arrested. On the whole, Mongol rule threw the country more than 200 years behind the other states of Europe. The principalities of Kiev and Tchernigov never recovered afterwards. Their decline, however, made room for the rise of Galitch to pre-eminence in western Russia, and, amidst wars against Hungary and the Tatars, it preserved greater independence than any of the Russian principalities till, in the later half of the 13th century, it was taken possession of by Casimir III. of Poland. About the same time Volhynia was joined to Lithuania. The rise of this latter state was much favoured by the prostration into which Russia had fallen; and after an existence of several centuries, during which it extended its power so as to include Livonia proper, the Russian provinces of White Russia, Volhynia, Podolia, and the Ukraine, it was joined in 1569 to Poland (q.v.). On the north of Lithuania arose in the beginning of the 13th century another power, the Livonian Knights Sword-bearers, who took possession of Livonia, Courland, and Esthonia, as well as some portions of the territory of Novgorod and Pskov; while the Scandinavians, blessed by Pope Gregory IX., undertook a crusade against Novgorod. They were, however, defeated by Alexander Nevski (q.v.; 1252-63).

In the beginning of the 14th century eastern Russia consisted of the principalities of Suzdal, Nijni-Novgorod, Ryazan, Tver, and Moscow, and long contests took place between them, especially between the latter two. At last Moscow—a small village fortified by Yuri Dolgoruki (1147)—took the upper hand. It was entirely free of municipal traditions, and the powers of the prince could freely develop there, unchecked by the *vetche*. It occupied an advantageous position at the junction of several main routes, and on a then navigable river, amidst a territory thickly peopled by boyars' peasants, who enriched the prince and the boyars. The church, always prosecuting its aim of creating a monarchy in Russia, soon perceived the importance of Moscow as a centre of a future state, and its head, the metropolitan, removed thither from Vladimir in 1225. The church, the boyars, and the princes thus created at Moscow the power which was necessary at that moment to oppose the encroachments of Catholic Lithuania, Poland, and Livonia. Ivan Kalita (1288-40), Simeon the Proud (1340-53), and the regency of boyars which administered the affairs under his weak-minded son Ivan II. (1353-59), and also during the minority of Ivan's son Dmitri Donskoi (1359-89), all pursued the same policy of increasing the powers of Moscow by weakening the neighbouring principalities—Nijni-Novgorod, Tver, and Ryazan. Taking advantage of the weakness of the Mongol khanate, now divided into the hordes of Nogai,

Crimea, Kazan, and Astrakhan, the east Russians made in 1380 the first attempt at throwing off the yoke; their armies federated under Dmitri, and they ventured for the first time to meet the Mongol armies in a battle on the field of Kulikovo, on the banks of the Don. The battle was not decisive, but the church ascribed the victory to the holy icons of the Moscow monasteries and to Dmitri. True, next year the Khan Tokhtamysh advanced suddenly on Moscow, burned it, killed no less than 24,000 people, and exacted a heavy tribute. But this was the last time that Moscow fell into the hands of the Tatars. Its Krenl (citadel), which had resisted in 1368 and 1371 the assaults of the Lithuanians under Olgerd, was more strongly fortified, and when Khan Edigheï besieged it in 1408 he could only ravage the suburbs.

The gradual increase of the Moscow principality continued under Vassili I. (1389-1425)—who bought from the khan the right of ruling at Nijni-Novgorod, and conquered Rostov and Murom—and Vassili II. the Blind (1425-62). Still the prince, though assuming the title of Great Prince, was merely recognised as the eldest by other princes, and the cities maintained their independence, simply paying to his delegates a tribute in exchange for military protection, while Moscow was ruled in reality by the *duma* (council) of the boyars, especially after Vassili II. became blind. It was under Ivan III. (1462-1505), named 'the Great' by some historians, that the prince of Moscow, after having for forty years seized every opportunity for abolishing the autonomy of other principalities, and having married Sophia, a niece of Constantine Palaeologus (who came to Moscow with a numerous following of Greeks imbued with ideas of Roman autocracy), assumed the title of 'Ruler of all Russia' (*Hospodar Vseya Rossii*), and adopted the arms of the Byzantine empire. He took advantage of the divisions at Novgorod between the oligarchy of merchants, who were appealing for assistance to the Poles, and the people, and, supported by Tatar cavalry, marched against the republic (1471). Novgorod was defeated and submitted; but new difficulties arose, and, after having preached a national war 'against the pope and his allies the Novgorodians,' Ivan took possession of the city (1481), decapitated numbers of boyars and rich people, and transported 8000 Novgorodians into the cities of eastern Russia. The colonies of Novgorod (Vyatka, Vrina) were conquered next, and in 1495 the Hanseatic market of Novgorod was pillaged by Ivan's men, and all the goods taken to Moscow. Novgorod thus lost both its independence and its trade.

The Tatar-Mongols being divided at this time, the Russians took advantage of the fact to refuse tribute; and when thereupon the khan of the Golden Horde, stimulated by Casimir's promises of support, marched against Moscow, an army of 150,000 men was sent to meet him on the Oka. Both armies stood there for months inactive, till, finally, the Tatars, seeing no support from Lithuania, and probably learning that Sarai had been plundered by a straggling band of Russians, suddenly retreated to ravage Lithuanian territory. This retreat is considered as the liberation of Russia from the Tatar-Mongol yoke (1480).

Russia's chief enemy, however, was Lithuania, united at that time with Poland. It stood at the very gates of Moscow, keeping garrisons in towns 150 miles distant from the Russian capital, and always ready to employ the Tatars against the Russians. A protracted war ensued, with the result that several princes on the upper Oka and Desna (tributary to the Dnieper) surrendered to Ivan. Smolensk, however, remained under the Lithuanians. Vassili III. (1505-33) followed his

father's policy. He continued the war with Lithuania, and retook Smolensk. He annexed Ryazan and Novgorod-Syversk, and conquered, by taking advantage of its internal dissensions, the last north-western republic, Pskov. The *vetche* was abolished, its bell taken to Moscow, and 300 wealthy families transported to east Russia.

Vassili's son, Ivan IV. (1533-84), was proclaimed Great Prince when he was only three years old. His reign is still the subject of the most contradictory estimates by historians. The fact is that by that time the boyars of Moscow, reinforced by all the dethroned princes and their descendants, had grown all-powerful. Not only the laws were issued by the boyar *duma* (council) in the name of 'the Great Prince and the boyars,' but their authority within the palace overshadowed that of the prince. In his childhood Ivan IV., though surrounded with adulation at official receptions, was kept in neglect and almost hunger. Russia was like to become another Poland ruled by the rival parties of nobles. During the first years of his reign Ivan ruled with their support and under the influence of the priest Sylvester and the minor noble Adushev. The states-general were convoked twice (1549 and 1550), the code (*Sudebnik*) of his grandfather was revised, and church matters were settled in 'The Hundred Articles' (*Stoglav*) by a council. Kazan was conquered in 1552, and Astrakhan two years later. But within the palace affairs stood at their worst. Ivan's two advisers, grown very powerful, were gained over to a party hostile to Ivan and favourable to his cousin, and when Ivan fell ill (1553) he witnessed during his sufferings the intrigues of his advisers. Once recovered, he exiled them. At the same time a mighty feudal prince, Andrei Kurbiski, openly went over to the service of Lithuania, while other boyars maintained a secret understanding with Poland to place on the throne a ruler who might be their tool. Ivan IV. began most cruelly to persecute the boyars, and his cruelty soon attained the pitch of real madness. No less than 3470 victims, out of whom 986 are mentioned by name, were inscribed by Ivan IV. himself in his prayer-book, and among them are whole families 'with sons and daughters,' as well as 1505 Novgorodians, 'whose names, Almighty, Thon knowest.' Ivan's historical position appears very much like that of Louis XI.: it was the royal power struggling against the feudal oligarchy; but the struggle took a truly Asiatic character of refined cruelty, mingled with orgies and acts of monastic devotion. In order to carry on the struggle more successfully Ivan gave liberties to the towns and later on divided all Russia into two parts—the country as a whole and, on the other hand, what he claimed as his own part of the country (*oprichnina*)—the latter having the right of oppressing the former, peasants and boyars alike. Ivan IV. was the first autocrat in Russia, and he assumed the title of *tsar* (erroneously spelt *Czar*, q.v.), which is the name given in the Russian translations of the Bible to the kings of Judea and the Roman emperors. Contrary to the advice of his boyars, but with the approval of the states-general, he carried on a long and protracted war against Livonia, successful at the beginning, but most disastrous when Livonia was supported by the newly-elected king of Poland, Stephen Bathory. At the same time the khan Devlet Ghirei, crossing the Oka with 120,000 men, appeared before Moscow, and burned its suburbs. The Kremlin only resisted, and the khan retreated ravaging the country and carrying away countless prisoners. By the end of Ivan's reign Siberia (q.v.) was conquered by bands of Cossacks under Yermak, and the English opened the trade by sea with Archangel.

Ivan IV., who had himself killed his eldest son in a fit of rage, left but a feeble-minded son, Feodor (1584-98), during whose reign the boyars recovered their former power. Feodor's brother-in-law, Boris Godunov, was nominated regent, and the old struggles between rival parties began afresh. Godunov, though an able administrator, was generally hated by both the boyars and the people of Moscow, and he endeavoured to gain popularity among the minor nobility, in the interests of whom he promulgated (1597) a law which ultimately, especially after the law of 1648, developed into serfdom. Until that time the peasants remained free—*nominally, at least*. They were free to settle wherever they were offered the most advantageous conditions, and once a year (on St George's day) they were entitled to abandon their farms and to remove elsewhere if they had succeeded in finding better terms, and had contracted no debts with the landowner. Boris Godunov abolished that right of free removal, thus attaching the peasants to the land, and the institution, developing into full serfdom, became the curse of Russia for the next 270 years. To secure the throne for himself and his dynasty, Godunov first exiled Feodor and his mother to Uglich, and later on sent assassins to murder the seven years' old child Dmitri in 1591. After Feodor's death the *duma* of boyars proclaimed Boris Godunov (1598-1605) tsar of Russia, but he reigned six years only.

The most extraordinary thing then happened in Russia. A young man, supposed to be Grigoriy Otrepiev—a runaway monk from a Moscow monastery who had afterwards spent several years among the Zaporogian Cossacks—appeared in Poland under the name of the assassinated Dmitri. The Jesuits and some of the Polish nobility at once supported him; also King Sigismund; and when he appeared with an army of Polish volunteers, under the walls of a Russian frontier fortress, he was received as the very son of Ivan IV. All over Russia the people rose to support the pretender. The mother of the murdered Dmitri recognised him as her son, and when Boris Godunov suddenly died at this juncture, Dmitri was proclaimed tsar; he was received as such at Moscow, and crowned (1605). He returned to the peasants the freedom they had lost under Godunov; but the people of Russia did not find in him the Russian tsar they expected to find. He was a mere instrument in the hands of the Poles, he married a Pole, and his Polish garrison exasperated the people of Moscow. A revolt headed by Prince Vassili Shuisky (1606-10) broke out. The impostor was murdered, and Shuisky proclaimed tsar by the boyars. But Russia did not recognise him. New impostors appeared and were supported by the revolted peasants, while bands of runaway peasants who had gathered during the preceding decades on the banks of the Don and Dnieper under the name of Cossacks ('free men'), invaded Russia, devastating the provinces, and robbing the nobles, the towns, and the wealthier peasants. Sigismund of Poland, taking advantage of the confusion, invaded Russia, and with the consent of the Moscow boyars proclaimed his son Vladislav tsar; but he preferred to have Russia for himself, and took possession of Moscow (1610). Shuisky was taken to Poland, where he died in a prison.

All this would appear difficult to explain, unless the following be taken into account. Russia by that time was receiving western civilisation from Poland, and the boyars were the first to accept it in appearance, imitating the extravagant life of the Polish nobles, ruining the peasantry, and aiming at an oligarchy of nobles such as they saw in Poland. The great rising of the people of Russia, which began in 1601 under the banner of the false

Dmitri, and continued during the next eleven years, was a rising of the toiling masses and small traders against the boyars. But this rising had, at the same time, opened Russia to Polish invasion, and left the whole territory—landlords and peasants alike—at the mercy of predatory gangs of Cossack and Polish robbers. A reaction was inevitable, and it came from the cities supported by the church. A cattle-trader of Nijni-Novgorod, Minin, aroused his fellow-citizens to march for the delivery of Moscow, which was held by the Poles and besieged by the Cossacks. The same movement took place in all Russian cities, and their folk-moots (*vetche*) entered into agreements to levy militias and unite them into one army, and convoked a 'General Council of the Land,' composed of representatives of all classes at Yaroslavl. Under the leadership of Prince Pozharskiy and Lapunov they retook Moscow, drove the Poles out of Russia, and the council (*Sobor*), now moving to Moscow, was urged to elect a tsar. The boyars were inclined to elect a Swedish or Polish prince, but the lower orders and the clergy opposed this, and the *Sobor* elected Mikhael Romanov (1612-45). The boyars finally acquiesced in the hope of maintaining the power under a sixteen-year-old tsar; but the *Sobor* remained quasi-permanent at Moscow during the first ten years of Mikhael's reign, and all decisions were issued conjointly in the name of the tsar and of the *Sobor*. Mikhael Romanov belonged to a family (the ancestors of which had emigrated in olden times from Prussia) which was very popular now in Russia. His father, the Rostov metropolitan Philarete, who had been sent as an envoy to Poland, was kept imprisoned by the Poles; his uncles had died in prisons under Boris Godunov; and his grandmother, who was the first wife of Ivan IV., had left a very good memory behind her.

The first years of the reign of Mikhael Romanov were characterised by a general movement on the part of the Russian towns to crush the peasants' insurrection and to extirpate the bands of robbers. Peace was obtained from Gustavus Adolphus of Sweden by abandoning Schlüsselburg; but the war against Poland continued, notwithstanding a short armistice. The states-general, convoked again (1632 and 1642), freely voted fresh subsidies, but no success was obtained, and the very existence of Russia was menaced when the revolts of the Cossacks of the Dnieper against the Polish nobles changed the face of affairs in favour of Russia.

Under Mikhael's son Alexei (1645-76) the work of modelling Russia into a state continued, and the local administration was entirely reformed. But the revolts of the people began anew, especially since serfdom was enforced by the law elaborated by the states-general of 1648, and the first half of Alexei's reign was marked by a series of popular revolts at Moscow, Nijni, Pskov, and finally in south-east Russia, under Stenka Razin, when the runaway serfs and the free Cossacks of the Volga rose fiercely against Russia, hanging the landlords, and aiming at 'settling their accounts with the boyars in the Kremlin itself.' At the same time came the great disruption (*raskol*) in the church. The patriarch Nikon was striving to acquire in the East the same supremacy as the pope had in the West. Being himself one of the richest serf-owners in Russia, he made a display of extravagant luxury in his life; he surrounded himself with a kind of ecclesiastical court which plundered the lower clergy; he built under Moscow a 'New Jerusalem,' and in processions went preceded by a 'Latin cross' (with one cross-bar only) like the pope. In short, he was considered 'Latin' (i.e. Polish) in all his arrogant behaviour. His attempt at completing the already undertaken revision of the sacred books, into which many errors had crept through

illiterate copyists, became the signal of a revolt of the bulk of the nation against the state's 'Latin' Church. A popular church, having priests elected by the parishioners, and taking the 'old faith' for its watchword, was opposed by the people to 'Nikon's Church,' although its followers were pitilessly tortured and exterminated by the state. All great subsequent risings of the peasants (Razin's, Pugachev's, and many smaller ones) were therefore made under the cross with eight ends (three cross-bars) of the 'old faith.'

Nikon's attempts at subduing the tsar to his arrogant supremacy ended in his deposition and exile, and later on Peter I. abolished even the dignity of patriarch, substituting for it the Holy Synod. Alexei frequently convoked the states-general, first to confirm his accession to the throne (1645), then to revise the existing laws and to compile (1648) a new code (*Sobornoe Ulozhenie*), and next (1651 and 1653) to pronounce upon the annexation of Little Russia. Under Alexei Russia finally gained the mastery over Poland, and reconquered Smolensk; but her success was chiefly due to the revolt, under Bogdan Hmelnitsky, of the Orthodox Cossacks of Little Russia, who were terribly oppressed by their Catholic landlords. After seeing the impossibility of resisting Poland single-handed, the Cossacks appealed for protection to Russia, and recognised her supremacy. This event decidedly turned the scales in favour of Russia in the long struggle between the two chief Slav powers. But in order to maintain her rights on the Dnieper Russia had now to sustain a war with Turkey, which continued till after the accession of Feodor (1676-82), when it was terminated (1681) by the treaty of Bakhtchisarai, by which Turkey gave up all claims upon Little Russia. After Feodor's death the states-general chose his half-brother Peter as tsar, but his half-sister Sophia, an able and ambitious princess (see PETER THE GREAT), succeeded in obtaining the reins of power as princess-regent. She concluded peace with Poland in 1686, made two unsuccessful campaigns against the Tatars of the Crimea; and after an attempt to deprive Peter of his right to the throne, and this failing, to assassinate him and his mother, she was forced to resign all power and retire to a convent. Nearly a thousand of her accomplices were executed; and Peter (1689-1725) ascended the throne as sole ruler, his half-brother Ivan being allowed to retain the title of tsar conjointly, and to appear as such at public ceremonies, but without any real authority.

The history of Peter I.'s reign is almost entirely his own biography, and it is given under his name, the following remarks being only intended to give a general view of the importance of his reforms.

The powers of the tsar, the *duma* of boyars, and the church have already been mentioned above; but since Ivan IV.'s time, and especially since the 'troubled times' of 1601-12, a new power had come into existence—viz. the *Sobor*, or states-general. The *Sobors* consisted of representatives of either 'the whole land,' or special classes—merchants or military—or the inhabitants of Moscow only, and they exercised a decided influence upon legislation. But even in Alexei's reign steps were taken towards centralising all powers in the hands of various boards (*prikazy*) corresponding to modern ministries, under the guidance of the tsar, and the *Sobors* were convoked less and less frequently. Peter I. totally destroyed the powers of the boyars and the church, and convoked the states-general but once, to condemn his sister Sophia. He proclaimed himself emperor, abolished the rank of patriarch, and introduced, instead of the *duma* and the *Sobor*, a senate, whose members he nominated himself. By transporting

his capital to St Petersburg, a city of his own creation, he entirely freed himself from the interference of the boyars, the church, and the people of Moscow, which often made its voice heard by means of rebellions. He ruled with absolute power, supported by men of his own choice. All Russians became in an equal degree his own subjects, though class-distinctions continued to prevail in their mutual relations, and serfdom grew worse and worse, taking all the characters of slavery. Of a standing army under Peter's predecessors only the *Strzeltsy* (military settlements in the suburbs of the cities) and the Cossacks deserved the name. The former were abolished after their revolts in favour of Sophia, and the privileges of the latter were curtailed. A standing army, completed by recruiting, was introduced. The whole administration was reorganised upon German models, or on strongly hierarchical and centralised principles. A secret state police, endowed with extensive powers of imprisonment, torture, and exile, was introduced, and among its victims was Peter's only son, Alexei, convicted of having plotted with the old party against his father. He died after torture. The old taxes by household were superseded by capitation taxes, and formidably increased. Written procedure was introduced in the justice courts, stamp-duties were imposed. Faith was made a state affair, and attendance at church on Sundays and communion once a year was rendered obligatory.

Agriculture and industry were at a low ebb in the tsardom of Moscow. Civilisation and learning, which had been introduced during the federative period, had never recovered the shock they had received from the Mongol invasion. The education even of the higher classes was confined to reading and writing, and the first school for classics and theology only made its appearance during Feodor's reign. Fine arts were limited to architecture and painting (of sacred subjects) after the Byzantine school. The first newspaper appeared (in Moscow), and the first theatre was established, during the reign of Alexei. The influence of the Mongols left deep traces on the domestic manners and habits of the Russians, among which was the low position of women in domestic life; those of higher rank were completely excluded from social intercourse with the other sex, and were condemned to pass a dull and dreary existence in their 'terems.' Peter I. did his best to improve the state of affairs in all these directions. He organised the army, created mining and manufactures, chiefly for state purposes, imported improved races of cattle, traced and caused to be dug the canals which now are so important for Russia, created schools, chiefly technical, and introduced more social intercourse between the different classes of society, in which women were allotted a share. It must, however, be noted, that in the carrying out of his well-meant schemes he forgot the people for the state, and imposed upon the former the most terrible burdens. Thousands and thousands of his subjects perished in erecting St Petersburg and its fortress and in digging canals, not to say a word of the wars they had to maintain, and the revolts crushed with Asiatic cruelty.

In accordance with the terms of his will, his second wife, Catharine I. (1725-27), succeeded him; but the old or anti-reform party of the nobility supported the claims of the only son of the unfortunate Alexei, Peter II. (1727-30), who soon after obtained the imperial throne. The reigns of both of these sovereigns were occupied with court quarrels and intrigues, Menshikov (q.v.) during the former, and Dolgoruki during the latter being the real rulers. On the death of

Peter II. the privy-council, setting aside the other descendants of Peter I., conferred the crown on Anna, Duchess of Courland, the daughter of Ivan. Her reign (1730-40) was marked by the predominance of the German party at court, who, unchecked by the weak sovereign, treated Russia as a great emporium of plunder (see BIRON). Under their influence Russia restored to Persia her lost Caspian provinces, and was led into a most ruinous war with Turkey. Anna's successor was Ivan (1740-41), the son of her niece, the Duchess of Brunswick, Anna Carlovna; but he was speedily dethroned by Elizabeth (1741-62), the daughter of Peter I., who deprived the German party of the influence it had so shamefully abused, restored the senate to the power with which it had been entrusted by Peter the Great, established a regular system of recruiting, abolished tolls, and increased the duties on imports. Russia gained by the treaty of Åbo (1743) a portion of Finland, and took part in the Seven Years' War (q.v.).

Elizabeth's nephew and successor, Peter III. (q.v.; 1762), was a devoted admirer of Frederick the Great of Prussia. His first act on his accession to the throne was to order the Russian army which supported the Austrians against Prussia to join Frederick against the Austrians. Prussia, reduced to the last extremity, was thus saved from dismemberment. At home he abolished the prescriptions of Peter I. which imposed upon each noble the duty of entering the state's service; he abolished the secret state police, gave full liberty to the *raskolniks*, proclaimed an amnesty to the serfs who had revolted against their owners, and proposed to seize the estates of the convents—a measure which Peter I. did not dare to take, and which was partially accomplished subsequently under Catharine II. But he was disliked at the court, and his wife, Catharine II. (1762-96), easily dethroned him. He was arrested and murdered by Catharine's associates.

Under Catharine II. (q.v.) successful wars were carried on against Turkey, Persia, Sweden, and Poland, which largely extended the limits of the empire. The acquisition of the Crimea, which gave Russia a firm footing on the Black Sea, and the first partition of Poland, were two most important steps towards the consolidation of the empire. In home affairs the work of further centralisation was prosecuted. But, notwithstanding Catharine's friendship with the 'Encyclopædists' of France and the excellent ideas expressed both in her correspondence and in various 'Instructions' (*nakazy*), her reign was exceedingly oppressive for the peasants. The rights of the landlords over their serfs were extended; no less than 800,000 free peasants were distributed as serfs among Catharine's favourites; serfdom, abolished in Little Russia by Bogdan Hmelnitsky, was reintroduced there as well as among the Don Cossacks; and once again the whole state was shaken by the impostor Pugachev, who, supported by the *raskolnik* Ural Cossacks, pitilessly hanged the landlords and officials in east Russia, ravaging the country under the assumed name of Peter III.

Catharine's son and successor, Paul I. (1796-1801), at first, through apprehension of the revolution in France, joined the Austrians and British against France, but soon after capriciously withdrew, and was about to commence war with Britain when his assassination took place. He gave freedom of worship to the 'Old Ritualists,' but recklessly turned free crown peasants into serfs for his favourites. He established a severe censorship of the press, prohibited the introduction of foreign publications, reorganised the secret police, and altogether treated his subjects in the most contemptuous way. A palace conspiracy put an end to his reign and life.

His eldest son, Alexander I. (1801-25), was at the outset desirous of peace, but was soon drawn into the vortex of the great struggle with France, in which he played a prominent part. The character of his rule is sketched under his name, and an outline of the warlike operations—the great French invasion of 1812, the burning of Moscow, and the disastrous retreat—is given in the article NAPOLEON. The Holy Alliance (q.v.) and the example of conservative policy set by Austria exercised a pernicious influence on the later part of his reign; and the higher classes, who had looked for the introduction of at least a portion of the liberal institutions they had seen and admired in western Europe, became so dissatisfied that, when his youngest brother, Nicholas I. (1825-55), from whom they had nothing to hope, succeeded, they broke out into open rebellion, which was speedily crushed. A full stop was now put to the intellectual development of Russia. Wars were declared with Persia and Turkey; and a long and deadly struggle commenced with the Caucasian mountaineers. The cession of Erivan and Nahichevan by Persia, of the plain of the Kubañ, of the protectorate of the Danubian principalities, and of the free right of navigation of the Black Sea, the Dardanelles, and the Danube by Turkey only induced him to further prosecute his aim of conquering for Russia a free issue from the Black Sea in the Dardanelles. In 1830 he converted Poland (q.v.) into a Russian province; in 1849 he aided Austria in quelling the insurrection of the Magyars; and in 1853 he began a war with Turkey which became the Crimean War (q.v.), and in which, though the allies, Britain, France, and Sardinia, did not obtain any decided success, Russia suffered immense loss.

The accession of Nicholas's son, Alexander II. (1855-81)—one of whose first acts was the conclusion of the peace of Paris (1856), by which Russia lost the right of navigation on the Danube, a strip of territory to the north of that river, and the right of keeping a navy in the Black Sea—was the signal for a general revival of intellectual life in Russia. Public opinion broke the bonds of censorship and constrained the well-meaning but weak emperor to carry through the long-expected abolition of serfdom. It was abolished in 1861 after many hesitations. Corporal punishment was abolished and the judicial organisation was completely revised (1864). Unhappily the insurrection of Poland (1863-64) put an end to the reform period. The old serf-owners' party took again upper hand, and the last great reform, by which self-government (*zemstvo*) was granted to the provinces (1866), did not receive the importance which it formerly was proposed to give to it, as a preparatory step to constitutional government. Obligatory military service for all Russians was introduced in 1874.

The insurrection in Poland was suppressed with extreme severity; and in 1868 the last relics of Polish independence disappeared in the thorough incorporation of the kingdom with the Russian empire. The subjugation of the Caucasus was completed in 1859. Russian supremacy was established over all the states of Turkestan. In 1876 the administration of the Baltic Provinces was merged in that of the central government; but the autonomy of Finland was respected and even extended. In 1870, during the Franco-German war, Russia declared that she considered herself bound no more to the obligation of keeping no navy in the Black Sea, and in a conference at London in 1871 her claims were recognised. The misgovernment of her Christian subjects by Turkey, and her cruel suppression of incipient rebellion in 1876, led to a conference of

the European Powers at Constantinople. Turkey rejected the proposals made by the conference with a view to the better administration of the subject provinces; and Russia, to enforce these concessions on Turkey, declared war in April 1877. At first the Russian progress was rapid; but the energy displayed by the Turks during the summer, and the resolute defence of Plevna by Osman Pasha from July till December, checked the progress of the Russian army. During the winter, however, she crossed the Balkans, and her vanguard reaching the Sea of Marmora, stood in view of Constantinople. The armistice signed in January 1878 was followed in March by the treaty of San Stefano; and after diplomatic difficulties that seemed for a time not unlikely to issue in war between Russia and England, a Congress of the Great Powers met at Berlin in June 1878, sanctioned the re-arrangement of the Ottoman empire explained under the article TURKEY, and the cession to Russia of the part of Bessarabia given to Moldavia in 1856, as also of the port of Batumi, of Kars, and of Ardahan. The growth of revolutionary discontent (see NIHILISM), leading to severe repressive measures, was marked by several murders of high officials; and on 13th March 1881, Alexander II. was killed by the revolutionists.

The reign of Alexander III. (1881-94) was in the main characterised, in contrast to the liberal reforms of the last reign, by reactionary steps; though strenuous efforts were made to put an end to the colossal plundering of state money and appropriation of state lands common in the last half of the reign of Alexander II. The self-government of the *zemstvo* had been limited and put under the authority of the nobility; the justices of peace were abolished, and an attempt at reintroducing manorial rights had been made. The redemption taxes imposed upon the liberated serfs were slightly reduced. Oppressive measures led to wholesale and compulsory emigration of Jews, and the autonomy of Finland was curtailed. Under Nicholas II. (1894-1917) the French alliance was cherished; in 1898 Manchuria (q.v.) became mainly a Russian province, and Tientsin and Port Arthur Russian ports. Collision of interests in Manchuria and Korea led to the war with Japan in 1904-5, in which the Russian armies were disastrously defeated in numerous bloody engagements (see JAPAN), including that before Mukden; Port Arthur capitulated after a siege of eight months; and the two fleets were destroyed. Peace was concluded at Portsmouth, N.H., on 5th September 1905 (see JAPAN).

On the conclusion of the disastrous war with Japan, the discontent which had been slumbering during 1904 broke out into open anarchy. Strikes of workmen in all the important centres, preferring political as well as social demands, became general, continued throughout 1905, and in many cases were put down by military force. In St Petersburg the strikers numbered in January over 100,000, led by a priest, Father Gapon. A procession marched to the palace to interview the tsar, but was met by troops, who killed and wounded hundreds. At Moscow the Grand-duke Sergius was assassinated by a bomb (17th February). By October over 1,000,000 men were estimated to be on strike, including all the railway and telegraph services; famine threatened many cities, lighting was cut off, and anarchy had become general. Poland was practically under military law, and in the Caucasus a condition of civil war existed between Tatars and Armenians. At Baku the governor was killed by a bomb (9th March), enormous damage was done to the oil wells and refineries, about 1000 people were killed and several thousands wounded. The discontent spread to the peasantry.

Anti-Jewish crusades took place in many districts, and horrible outrages were perpetrated. Mutinies took place among the sailors of the fleet at Odessa, Cronstadt, Vladivostok, and Sebastopol. These strikes and disorders were mostly political in their aims, and demanded an immediate reform in the government of the country. A congress of 34 presidents of *zemstvos* in December 1904 had passed resolutions demanding great reforms, and the resulting manifesto by the tsar (27th December), while promising certain improvements, was looked upon as a general refusal of self-government. On 1st February the tsar received a deputation of workmen, and promised to ameliorate their lot, but reproved the disorders. On 3rd March he issued another manifesto, appealing to the people for peace, and promising to convene a legislative assembly elected by the people; but this was not considered thorough enough, and the disorders continued. In August still another manifesto provided for the assembly of a popularly elected National Duma or representative council in January 1906, to establish a modified form of constitutional government. The *zemstvo* congress at Moscow, in September, gave this scheme a hesitating and grudging support. Meanwhile, the disorders increasing, the tsar signed a constitution (30th October), and appointed Count Witte head of a responsible ministry. Towards the end of 1905 the strikes were partially composed, but disorders in a lesser degree and repression by force continued into 1906. In the Duma, which met in May 1906, the revolutionary elements secured the predominance, and on 21st July it was suddenly dissolved by the tsar.

The second Duma (1907) was similarly short-lived. Stolypin, minister from 1906, set himself to undo the work of reform. Changes arbitrarily made in the electoral law secured a mainly conservative but not always tractable third and fourth Duma (1907-12, 1912-17). Stolypin's attempt to substitute individual for communal land-ownership among the peasants had only a limited measure of success, and failed to produce the good he looked for. Suppression of subject nationalities went on. Stolypin was stabbed at Kiev in 1911. Gorenkyin (1914-17) took up his work. Russia had not allowed the Serbs to drag her into war in 1908; but in 1914 she came ill prepared to the help of the southern Slavs. See WAR (GREAT). Armies were thrown away upon the battlefield unarmoured and ill led. Incompetence, corruption, bigotry, court scandals, economic breakdown, prepared for the revolution that swept away the old system.

Some account of the dissensions among the Russian Socialists and of the Workmen's and Soldier's Soviets or Councils will be found in the article SOCIALISM. See also BOLSHEVIK, COMMUNISM, and for the theory of a dictatorship of the proletariat to clear the way for a truly Socialistic system, see DICTATOR. At first however all progressive parties shared in the work. The revolution grew out of food riots in St Petersburg (March 1917), leading to a revolt of the garrison. The movement was met in the usual way but without success. A provisional government was formed under Prince Georgi Evgenievich Lvov, a Liberal. In July he resigned and Kerensky succeeded, an orator more than a statesman. Kerensky maintained his position against the attempted *coup d'état* of Kornilov (September), but fell before the Bolsheviks in November. A republic had been proclaimed on the 16th September 1917. Up to this point the all but bloodless revolution had been more or less sympathetically received abroad. To the Allies the great thing was to get on with the war. A democratic Russia, a good thing in itself, removed a reproach and

bettered their cause. The war-weary Russians, however, felt that a war for Constantinople was no war of theirs, nor the obligations of their overthrown masters binding upon the freed people. While the government had been prosecuting the war the Soviets had been preaching peace without annexations or indemnities, and organising the soldiers in councils. Backed by the army and the Baltic fleet the Soviets, representing the Bolsheviks under Lenin, drove out the provisional government 7th November 1917, dissolved the Constituent Assembly which had been convoked to fix the constitution, concluded the peace of Brest-Litovsk with the Central Powers—the Allies having refused to join in negotiation—and set about making a new Russia. They abjured imperialism with its subjection of nationalities and its secret treaties, pronounced for self-determination, nationalised land and industrial and commercial enterprise. Nicholas II. and his family were shot at Sverdlovsk by order of the local Soviet. Europe was filled with tales—some true—of the Red Terror, and for some years Russia was in a welter. A White Terror arose against the Red, for both sides in Russia had learned too well the methods of the empire. Anti-Bolshevik governments were set up here and there. White leaders (Kolchak, Denikin, Wrangel, Yudenich) backed by foreign expeditions (British, French, Japanese, and others) closed in upon the Reds. Blockade, famine, disorganisation, war with Poland, left the Bolsheviks firmly fixed in power, defiantly propagating the Communist faith throughout the world. Opposition died away. It remained to be seen how far Bolshevism could cope with the difficulties of its stupendous task. Socialist visitors to Russia were by no means favourably impressed. Still less were capitalists. In 1921 it was found necessary to compromise. Lenin's new economic policy made considerable concessions to capitalism. The peasants when they had to hand over surplus produce to the state had aggravated the famine by producing only enough for their own families' needs. Allowed to sell their surplus corn and pay a tax they became exploiters, contrary to the spirit of the Communist constitution, but all the less dangerous to the Communist government. So was it in other matters. Lenin did not long survive those changes. He retired in ill health next year, and died in 1924. Nor were the Bolshevik chiefs, strong doctrinaires as they were, agreed about the wisdom of the concessions. Discussions ensued. Trotsky, Lenin's great fellow-worker, creator of the Red army, had to yield up the People's Commissariat of War in 1924. Dzerzhinsky, organiser of the terror, died in July 1926; and about the same time Trotsky's rival, Zinoviev, lost power.

See works on Russia by Sir D. M. Wallace (1877; new ed. 1912), Morfill (1882), A. J. C. Hare (1888), Stepaniak (Nihilist, 1885-88), Tikhomirov (1887), Leroy-Beaulieu (trans. 1893-94), Norman (1902), Baring (1911), Makoev and O'Hara (1925). For history, see the articles on the principal Russian sovereigns, notably those on Peter I., Catharine I. and II., Paul, Alexander I. and II., Nicholas I. and II., and on personages such as Bakunin, Herzen, Potemkin; also the articles on Anarchism, Bulgaria, Crimean War, Greek Church, Jews, Poland, Finland, Socialism, &c. And consult (beside the Russian historians named in the section on Russian literature and the works noted under PETER THE GREAT) Rambaud, *History of Russia* (1878; revised and continued by Haumont, 1914); the shorter history by Morfill (1902); *Ivan the Terrible*, by Waliszewski (trans. 1904); Skrine, *The Expansion of Russia* (1903); Fitzgerald Molloy, *The Russian Court in the Eighteenth Century* (1905); Nisbet Bain, *The First Romanovs* (1905), and *Slavonic Europe* (1907); Bertrand Russell, *Practice and Theory of Bolshevism* (1920); Kluchevsky, *History of Russia* (1911 et seq.); Mavor, *Economic History of Russia* (1914); Beazley, Forbes, and Birkett,

Language and Literature.—The Russian language belongs to the eastern branch of the Slavonic family. It is extremely copious, and resembles ancient Greek in being both synthetical and analytical; thus it has seven cases, and in no language are the prepositions used with more delicate precision. A few Latin and French words have been incorporated, but the tendency at the present time is to eject foreignisms as much as possible. The language has great capabilities for forming compounds and derivatives. There are many dialects, but the predominant literary language is that of Moscow. The first Russian grammar was published at Oxford in 1696 by Henry Ludolf; in Russian may be mentioned those of Vostokov (10th ed. 1839) and Bnsheev, *Historical Grammar of the Russian Language* (1875). For understanding the principles of Russian philology we must betake ourselves to the great work of Miklosich, *Vergleichende Grammatik der Slavischen Sprachen* (4 vols. 1879). The best dictionaries are those of the Russian Academy (Russe-Français, Makarov, 1874; new ed. 1892; Russian-English, Alexandrov, 1879). In English there are Russian grammars by Morfill (1889) and Riola (new ed. 1890).

The earliest Russian literature consists of the *byliny*, or legendary poems, which were orally communicated till they were committed to writing in modern times. These are divided into cycles—e.g. those of Vladimir, the prince of Kiev, of Novgorod, and of Moscow. There are large collections of them, and also of the *skazki*, or popular tales. The earliest manuscript which has been preserved of anything which can be said to be distinctly Russian is the codex of the Ostromir Gospels, written at Novgorod in the years 1056-57 by the deacon Gregory, for Ostromir the *posadnik* of Novgorod. After this we get *sborniki*, or collections of miscellaneous works, such as those compiled for the Grand-duke Sviatoslav, and some sermons by Luke, bishop of Novgorod, and others. With the so-called chronicle of Nestor begins the series of Russian annals. Nestor is supposed to have died about 1114. We have also chronicles of separate parts of Russia, such as Novgorod, Kiev, Pskov, and Volhynia. There is also the *Pouchenie*, or book of instruction, of Vladimir Monomakh, and the prose-poem called 'The Story of the Expedition of Igor' (*Storo o Polku Igorev'e*). The original manuscript of this production was burned in the fire at Moscow in 1812. Important are the Russian legal codes, the *Russkaya Pravda* of Yaroslav in the 12th century, and the *sudebniks* of Ivan III. and IV. In 1504 the first Russian book was printed at Moscow. To the reign of Ivan IV. (the Terrible) belongs the 'Book of Household Management,' assigned to the priest Sylvester. We also have the *Stoglar*, or book of church regulations, issued by Ivan in 1551. At the beginning of the 17th century we have the chronicle of Sergius Khasov, and towards the close of the same century the interesting work of Kotliakichin on Russia, which was discovered in manuscript in 1840. To the same period belong the writings of Ivan Krizhanich, who is generally reputed to be the father of Panslavism, and the poems and plays of Simeon Polotski (1628-80), who was the tutor to the children of the Emperor Alexei. In the reign of the latter monarch the Russians got back Kiev, which had long been in the hands of the Poles, and thus the culture of the West became accessible to them. With Polotski may be said to terminate the first period of Russian literature with its Byzantine influence.

The second period was to be commenced by the reforming measures of Peter the Great; and Russia now began to look to the West for her models. He established schools, and founded the celebrated Academy of St Petersburg. The first Russian poet of the new era was Antikh Kantemir (1708-44), who wrote some good satires in the style of Pope and Boileau. But the writer that exercised the greatest influence on Russian literature was Michael Lomonosov, who established the supremacy of the dialect of Great Russia. He was an indefatigable worker in many branches of learning, and earned his chief laurels in natural science. Trediakovski (1683-1769) did something for Russian versification, but was hardly more than a poetaster. Basil Tatistchev (1686-1750) laid the foundations of historical writing, as opposed to the mere chronicler, and Sumarokov (1718-77) those of the drama. A real national comedy was created by Denis von Visin (1745-92) and Kniazhinin also wrote plays with ability. Michael Kheraskov (1733-1801) composed two large epics, the *Rossiada* in twelve books, and *Vladimir* in eighteen, but they have now almost sunk into oblivion. The *Dushenka* of Bogdanovich (1743-1803) was at one time very popular. With Khemnitser begins the series of Russian fabulists. Gabriel Derzhavin (q.v.; 1743-1816) was the great poet of the age of Catharine. He celebrated her glories in many spirited odes. Prose literature was more slow in developing itself. An elegant style can hardly be said to have existed before the time of Nicholas Karamzin (q.v.; 1766-1826), renowned for his history of Russia. On the accession of Alexander I. literature advanced rapidly. The founder of the romantic school of poetry was Basil Zhukovski, who, although he wrote but few original pieces, was beneficial to his countrymen by his translations from English and German. Other poets of the period were Dmitriev and Batiushkov. The most brilliant author, however, of the new school was Alexander Pushkin (q.v.), the greatest poet whom Russia has yet produced, who has left some charming narratives in verse, and other works. The fables of Ivaan Krilof (q.v.; 1768-1844) enjoyed some popularity, while Lermontov (q.v.; 1814-41) used the language of everyday life for some graceful lyrics. Gogol (1809-52), despite elements of the burlesque and the romantic, can be said to anticipate the age of the realistic novel, a novel which chose its material from contemporary life, but at the same time laid more stress on character than on plot. The first period of realism, which covered the middle of the 19th century, is represented by Turgenev (1818-83), the possessor of an excellent lyrical style and also by Dostoevsky (1821-81) and Leo Tolstoy (1828-1910), both masters of the introspective and analytical novel. The former wrote excellent dialogue, was orthodox in belief but painted abnormal types; the latter excelled in narrative, was rationalistic, but reproduced 'slices of life.' The second period of realism is covered by Tolstoy (1860-1904) who, following the 'suggestive' style of Turgenev, reflected the intellectual bankruptcy of the end of the 19th century, and the third period by the sensational Gorky (b. 1867), Kuprin (b. 1870), Bunin (b. 1870), and Andreyev (1871-1919). Names of some importance are those of the memoir-writers Aksakov (1791-1859), and Herzen (q.v.; 1812-70), the novelist Gontchharov (q.v.; 1812-91), the satirist Saltykov (1826-89), the dramatist Ostrovsky (1812-70), the novelist Leskov (1831-95) and the philosopher Soloviev (1853-1900). With the 20th century a new tradition of symbolic metaphysical writing arose, and poetry now came into its own. To this group belong the novelist Merezhkowski

(b. 1865), the philosophers Rozanov (1856-1919) and Shestov (b. 1866), and the poets Sologub (also a story-writer; b. 1863), Ivanov (b. 1866), Bely (b. 1880), and Blok, the most significant of all (1880-1921), while the novelist Remizov (q.v.; b. 1871) represents rather a reaction to realism.

The Russians have made notable contributions to art and science, but especially in music, where the best-known names are those of Cui, Balikirev, Borodin, Mussorgsky and Rimsky-Korsakov (these constituting the group known as 'the five,' which had its centre in St Petersburg), Rubinstein and Tchaikovsky (representing Moscow), Glazunov, Rachmaninov, Scriabin and Stravinsky.

See the separate articles on the principal authors and composers; also Maurice Baring, *Landmarks in Russian Literature* (1910), and *Outline of Russian Literature* (1915); Prince Kropotkin, *Ideals and Realities in Russian Literature* (1905); Prince Mirsky, *Modern Russian Literature* (1925), and *Russian Literature, 1882-1925* (1926 et seq.); histories by Walszewski (1909) and Brückner (1906), and studies on contemporary novelists by Persky (1914), the last three works all having been translated into English; Wiener, *Anthology of Russian Literature* (1902-3); the *Oxford Book of Russian Verse*, ed. by Baring (1925); and various books on Russian music by Montagu-Nathan (see also the standard histories of music).

Russniaks. See RUTHENIANS.

Rust rapidly appears on malleable iron, steel, or cast-iron exposed to a moist atmosphere. But malleable or wrought iron, being nearly pure iron, rusts rather more readily than either of the others, which essentially contain a certain proportion of carbon (see IRON AND STEEL). When a drop of rain falls on a clean bright surface of iron, for a short time the drop remains clear, showing the bright surface of the iron through it. But soon a greenish precipitate forms in the drop, and this rapidly becomes reddish brown. The brown precipitate or rust (essentially peroxide of iron) does not adhere to the iron, but is suspended in the water, and becomes a loosely adherent coating only when the water has evaporated. Iron remains quite free from rust in an atmosphere containing oxygen, carbonic acid, and water vapour (all present in a normal atmosphere except water vapour, which is rarely absent) as long as the water vapour does not condense as liquid water on the surface of the iron. Owing to the hygroscopic character of rust, when it once forms on iron the rusting process will continue in an atmosphere not saturated with water vapour. In other words, the iron in which a piece of clean iron will not rust, because liquid water will condense on rust when it will not on bright iron. The fact that under ordinary atmospheric conditions the rusting process, when once begun, continues, has been long known. It follows that it is much easier to prevent the first formation of rust than to stop the process.

It is customary to coat with oil paint all kinds of ironwork which are to be exposed to the weather, and this is usually a sufficient protection. But paint is liable to scale off, so that it is necessary to recoat the iron at longer or shorter intervals. A light iron fence, for example, would not long escape destruction by rusting if it were not frequently painted. It is, however, usual to 'galvanise' wire-work and thin sheets of iron, as the zinc coating retards oxidation. A coating of tin also protects the surface of iron from rusting, but it would appear that for this purpose it cannot be so much relied upon as zinc. Japanning (q.v.) is another way of preserving iron. The iron and steel plates forming the sides of ships receive four or five coats of a paint composed of red lead and boiled linseed-

oil to protect them from the corrosive action of seawater, and the sides of these ships are generally repainted after a long voyage. Some of our light-houses have water-tanks constructed of iron which is not only galvanised, but is also painted with three coats of this red lead paint above the zinc coating. The patent paints depend for their efficiency on the red lead and boiled oil in them. Unlike the peroxide, the magnetic oxide of iron forms an adherent coating to the metal, and only when it is detached can water gain access to the iron beneath it. In 1878 a patent (No. 1280) was taken out by G. & A. Bower for a process of producing a thin film of magnetic oxide on iron articles to protect them from rusting, but the colour of this oxide, which somewhat resembles that of the metal itself, is not attractive. In the comparatively dry atmosphere of occupied rooms the bright surface of iron or steel objects will often keep many years without rusting. Where such objects are care should be taken to keep away from them all volatile corrosive acids, such as nitric, hydrochloric, or acetic acid, or bleaching powder (chloride of lime). Polished surfaces of iron are often coated with tallow mixed with a little white lead for their temporary protection while they are being conveyed from place to place, but this sometimes fails to keep away rust. A more recent and better plan is to coat the bright iron with some varnish soluble in naphtha or paraffin-oil—Brunswick black, for example. A mixture of common rosin with a little pure olive oil and spirits of turpentine has also been found to be a good preservative in such cases. Iron immersed in an alkaline solution does not rust unless it is very dilute. Very delicate steel instruments are often protected from the action of moist air by placing them in drawers or cases along with chloride of calcium or lime hydrate, but as these substances absorb moisture and swell they require to be occasionally looked at. When bright iron or steel objects are already partially rusted, the rust, if not very deep into the metal, may be rubbed off with paraffin-oil, which contains no oxygen. Should this fail, a rub with fine emery will be necessary. Iron rust stains on linen or cotton are usually removed either with oxalic acid or binoxalate of potash (salt of sorrel). The fabric should be well washed after treatment with any of these substances.

The theory of rusting now generally accepted is that the carbon dioxide of the air dissolves in the water, forming carbonic acid; this dissolves the iron, forming ferrous carbonate; this in presence of oxygen is converted to hydrated ferric oxide or rust.

Rust. The popular name applied to a class of plant diseases caused by fungi belonging to the group *Uredineae*. The most important economically is Wheat Rust, which does damage amounting to several millions annually to the world's wheat crops. It is caused by the fungus *Puccinia graminis*, and is recognisable in early summer by the appearance of reddish orange streaks and spots on the leaves, from which is shed a reddish powder, the spores of the fungus. Towards the latter part of summer the orange 'rusty' spots give place to darker ones, when the plants are commonly said to be 'mildewed.' 'Rust' and 'Mildew' are now proved to be different stages in the life-history of the same fungus. Varieties of wheat show great differences in the degree of their susceptibility to attack, some being practically immune. Heavy applications of nitrogenous manures, especially nitrate, increase the susceptibility, and should therefore be avoided. See BARBERRY, PLANTS (Diseases). Other species of *Puccinia* occur on various cereals; on carnations, hollyhocks, asparagus, and plums among garden

plants; and on a great variety of wild flowering plants. Fungi of the closely related genus *Uromyces* occur on beans and beet. The biology of the group is very involved, and over 700 different species have been recorded.

Rustam. See FIRDŪSĪ.

Rustchuk, a town of Bulgaria, stands on the south bank of the Danube, opposite Giurgevo, 140 miles by rail NW. of Varna (on the Black Sea) and 40 S. by W. of Bucharest. It has numerous churches and mosques, and manufactures cloth, shoes, pottery, gold and silver ornaments, and furniture. It was captured by the Russians in 1810 and 1877, and played a prominent part in the Russo-Turkish wars of 1773-90 and 1853-54. Pop. (1920) 41,574.

Rustic Work is the name of that kind of masonry in which the various stones or courses are marked at the joints by spalls or recesses. The surface of the stone is sometimes left rough, and sometimes polished or otherwise dressed. Rustication is chiefly used in classical or Italian architecture, although rustic quoins are often used in rough Gothic work. In the figure *a* and *b* show

Rustication.

forms of rustication usually applied to surfaces, *c* and *d* show rustic quoins with mouldings on the angles.

Rüstringen, a seaport of Oldenburg situated on the west of the Jade Gulf. The town was severely inundated in the Middle Ages. Pop. 50,000.

Rutaceæ, a family of dicotyledons, consisting mostly of perennial or suffrutescent species, found chiefly in the tropics and the southern hemisphere, but also in the temperate regions of the northern hemisphere, and abundant along the shores of the Mediterranean. A bitter taste and powerful odour are general characteristics. Rue (*q.v.*) is a familiar example. See also AURANTIACEÆ, FLINDERIA.

Rutebeuf, or RUSTENEUF, a great 13th-century trouvère, of whose life we know but little, the dates of his birth and death being both unknown. His earliest extant poems are anterior to the final crusade of St Louis; his latest belong to the close of the reign of Philippe le Hardi. He lived a Bohemian life in Paris, amid poverty, debt, and constant distress, his miseries the fruit of an easy temper, lavish habits, a passion for gambling, and an unhappy marriage. His poems include *chansons*, satiric and religious, but not amatory; *complaintes* of death, in the name of contemporary great men; animal and moral allegories; dramatic monologues, among them the *Miracle de Thophile*, a clever drama of a compact concluded with the devil, from the consequences of which the victim is saved by the Virgin; metrical lives of St Mary of Egypt and St Elizabeth of Hungary; and fabliaux, full of honest gaiety. Rutebeuf was inspired by the

crusading fever, and took part in the great quarrel between the Dominicans and the regular clergy in the university of Paris, some of his best work being his satires against the religious orders, the mendicant friars, Dominicans and Minorites, and indeed all clerics, students alone excepted. His most striking qualities are strength, spirit, and colour, and some of his satires reveal a touching note of personality that reminds the reader of Villon.

His poems were edited by A. Kressner (Wolfenbüttel, 1885). See the study by Léon Clédat (1891) in *Les Grands Écrivains Français*.

Ruten, a Palestinian people, Aramæan or at least Semitic, with whom the Egyptians waged war under the 18th and 19th dynasties.

Ruth, BOOK OF. The four chapters of this canonical book tell how Ruth, a young Moabitess, after the early death of her Hebrew husband Mahlon, for the sake of her mother-in-law Naomi came to settle in Bethlehem, and there became the wife of a 'near kinsman' (*gôel*), Boaz, and the mother of Obed, grandfather of king David. The story is placed 'in the days when the judges judged' (i. 1), about a century before the time of David; but on its own showing it was not written till long after the events it describes (iv. 7). How long afterwards is a question on which critics are not agreed; most of them consider it to be exilic (Ewald) or rather post-exilic (Wellhausen, Kueneen, &c.), mainly on the linguistic and genealogical evidence; but Driver (*Introd. to Old Testament*, 1909) thinks that the general beauty and purity of the style, which stand on a level with the best parts of Samuel, point rather to a date, which he does not seek to fix more definitely, before the exile. That the book was not received into the canon till a very long time after the captivity is shown by its place in the original Hebrew, where it occurs as one of the Hagiographa or 'writings' (see BIBLE), standing second among the five Megilloth or Festal Rolls, between Canticles and Lamentations, a position which proves that it did not become canonical till after the series of 'former prophets,' extending from Joshua to 2 Kings, had been finally closed. In the Septuagint, however, which gives it the place it claims in the historical order, it comes between Judges and Samuel, and the same order is observed in the Vulgate and in the English versions. That Josephus also must have reckoned it as an appendix to Judges is shown by his enumeration of the books of the Old Testament as numbering only twenty-two. The purpose of the book has been variously explained. Some think that it was intended to inculcate the duty of Levirate marriage (Deut. xxv. 5-10, and see MARRIAGE); to this theory it is perhaps enough to reply that Boaz was not Mahlon's brother, and that David was never reckoned as the descendant of Mahlon. But the story undoubtedly has a bearing on the rights, duties, and privileges of the *gôels* or 'near kinsmen,' if these be taken in a somewhat wider sense. Others will have it that with the framers of the canon the interest of the book was chiefly genealogical. It certainly supplements the genealogy of David as given in the older books; in 1 Samuel, though relations with Moab are alluded to (xxii. 3), his ancestry is not traced beyond Jesse, and that the tendency of later ages was to greater amplification is shown incidentally by Matt. i. 5. But perhaps this little idyll of upright happy life in the good old God-fearing times, set forth with a simplicity and directness the charm of which no one can fail to feel, does not need any special indication of its claim to rank with the narratives of Genesis, Judges, or Kings.

See the Old Testament introductions, especially those of Driver, Moore, and Gray, also the commentaries on Judges and Ruth by Thatcher (*Century Bible*) and G. A. Cooke (*Cambridge Bible*).

Ruthenians, a branch of the Little Russian division of the Slav race, dwell on both sides of the Carpathians, in Eastern Galicia and Carpathian Ruthenia. They are of medium stature, but somewhat slim in build. Nevertheless they make hardy farmers, herdsmen, wood-cutters, and charcoal-burners—their favourite occupations. For various reasons—great subdivision of the soil, years of subjection to the Polish nobles, the extortion of the Jews, addiction to drink, and the lack of industries, though the house industries flourish—they are sunk in great poverty. The clergy of the Greek United Church, to which they are greatly devoted, are their intellectual and political leaders. The people cling to traditional usages and customs, and have a leaning to fatalism and melancholy. The Little Russians of the Ukraine are akin. Many of the Ruthenians of Galicia, deprived of their just rights by the Poles, have emigrated; many Canadians are of Ruthenian stock. See SLAVS, POLAND, RUSSIA, UKRAINE.

Western or Austrian Ukraine (or Ruthenia) in vain proclaimed its independence in November 1918, and in January 1919 its union with Eastern or Russian Ukraine. The peace treaties and subsequent arrangements left the Ruthenians more divided than ever. Russian Ukraine, a federal state of the Soviet Union, maintained some sort of independence, lopped of its western territories by Poland; but not so the former Austro-Hungarian territories. Eastern Galicia was left in Polish hands. Carpathian Ruthenia (Podkarpatská Rus; q.v.) was made an autonomous province of Czechoslovakia, and Bukovina (q.v.), and Bessarabia (q.v.; from Russia) went to Rumania. See H. Baerlein, *Over the Hills of Ruthenia* (1923).

Ruthenium (sym. Ru; atom. no. 44; atom. wt. 101.7; sp. gr. 12.3) is a metal discovered in 1843 by Claus in the ore of platinum. It forms no fewer than four different oxides. Of these the tetroxide, RuO₄, is remarkable for its volatility, boiling at a little above 100° C. For details regarding the metal, which is of no practical importance, the reader may consult Deville and Debray's *Memoir on Platinum and its Ores*.

Rutherford, SIR ERNEST, O.M., physicist, was born, 30th August 1871, at Nelson, New Zealand. After graduating at New Zealand University he proceeded to research work at Cambridge University, obtaining a further degree in 1897. From 1898 to 1907 he occupied the Macdonald chair of Physics in McGill University, Montreal; in 1907 he became Langworthy professor in Manchester University, and in 1919 Cavendish professor of Physics at Cambridge. Among medals and prizes awarded him are the Rumford Medal (1905), Nobel Prize for chemistry (1908), Bressa Prize (1908), and Copley Medal (1922). Knighted in 1914, he was President of the British Association in 1923, and received the Order of Merit in 1925. His work has largely dealt with the electrical conductivity of gases, and especially must his name be associated with researches in the field of radioactivity and investigations into the nature of the atom. His numerous publications include *Radioactivity* (1904), *Radio-active Transformations* (1906), *Radio-active Substances and their Radiations* (1912). See MATTER, PHYSICAL CHEMISTRY.

Rutherford, SAMUEL, Scottish preacher and divine, was born at the hamlet of Nisbet, near Jedburgh, about 1600. He attended school at Jedburgh, and entered Edinburgh College in 1617,

obtained a town bursary in 1618, and took his M.A. degree in 1621. Two years afterwards his extraordinary talent led to his appointment as regent or professor of Humanity, but an antenuptial irregularity with his wife caused his resignation in 1626, when he turned his attention to theological study. Through the influence of Gordon of Kennure, afterwards Viscount Kennure, he settled as minister of Anwoth in 1627. Here it was his habit to rise at three A.M. for study and prayer, and of his ministry it has been said that he was always praying, always preaching, always visiting the sick, always catechising, and always writing and studying. Though he had a kind of *skreigh* in his voice, Wodrow says he was 'one of the most moving and affectionate preachers in his time, or perhaps in any age of the church.' Here he began that correspondence with his godly friends, chiefly in Galloway and Ayrshire, which made him beloved, useful, and famous, and which earned the title when published of being 'the most seraphic book in our literature.' 'Hold off the Bible,' said Baxter, 'such a book the world never saw the like.' In 1636 his *Esercitantiones de Gratia* came out at Amsterdam, directed against the Arminians, with a second edition in the same year, and he was invited to fill a Divinity chair in Holland. Because of this work and non-compliance with Episcopal ceremonies, he was summoned before the High Commission Court at Wigtown on 27th July 1636, deprived of his ministerial office, and banished to Aberdeen. There he remained from September 1636 to February 1638, writing letters, disputing with Episcopalians, and bewailing his 'dumb Sabbaths.' He was restored to Anwoth, but was appointed by the Assembly professor of Divinity at St Andrews in 1639, became colleague to Robert Blair in the church of St Andrews, and afterwards principal of the New College (1647). Here he was as industrious as ever, performing the duties of both preacher and professor. In 1643 he was sent to the Westminster Assembly as a commissioner from the Church of Scotland, and there is a draft of a *Shorter Catechism* in his handwriting in Edinburgh University Library. During his four years' attendance he seems to have been prominent enough to be singled out for mention by Milton. His *Due Right of Presbyteries* (1644), *Lex Rex* (1644), *Trial and Triumph of Faith* (1645), *Christ Dying and Drawing Sinners to Himself* (1647) belong to this period. Rutherford's *Lex Rex* was conceived in too bold a spirit of freedom for the government of Charles II.; it was burned by the hangman in Edinburgh and by Sharpe at St Andrews in 1661. Its author was deposed from all his offices, and summoned to answer a charge of high-treason at next parliament. Rutherford received the citation on his death-bed, and sent answer, 'I behove to obey my first summons,' and went to a higher tribunal on 29th March 1661 (not 20th March, as his tombstone states); he was buried at St Andrews. There is a monument to his memory at Anwoth. No portrait of Rutherford exists, but he has been described as a 'little fair man' with 'two quick eyes'; when he walked he held his face upward. He was extremely charitable in private, and was much looked up to and consulted in matters of personal religion. Livingston, who knew him well, said 'he had most sharp piercing wit and fruitful invention and solid judgment.' He was twice married, and of seven children by his second wife, one daughter alone survived him. No divine in the first half of the 17th century has left a greater reputation for sanctity. He was twice offered a professor's chair in Holland. Freedom and breadth theologically, along with hardness and narrowness ecclesiastically, meet in Rutherford's published works.

Rutherford's religious genius is seen at its highest in his *Letters*, which, to the number of 284, were collected and published under the title of *Joshua Redivivus* by his secretary M'Ward (Rotterdam, 1664). A third edition in 1675 had 68 additional letters. Over twenty-five different editions have since appeared, the best being that by Andrew A. Bonar, D.D., with biographical sketch of his life and notes regarding his correspondents (Edin. 1801). Sixteen works, controversial or theological, were issued in his lifetime; his *Lex Rer.*, dealing with the prerogative of king and people, is as keenly logical and controversial as his letters are unworldly and full of sweetness, fancy, and spiritual life. Among his posthumous works are *Twelve Communion Sermons* (1876), and *Quaint Sermons*, edited by Bonar (1885).

See Taylor Innes in the *Evangelical Succession Lectures*; M'Adam Muir in the *St Giles' Lectures*; Dr Whyte's *Lectures* (1894); Livingston's *Characteristics*; and Lives by Murray (1828) and Thomson (1884). For the scandal of his youth, see the Edinburgh Town Council Records of date 3d February 1626.

Rutherglen (popularly *Ruglen*), a town in Lanarkshire, on the Clyde, 3 miles SE. of Glasgow, with whose eastern extremity it is connected by a bridge. It consists of one long wide street, with several narrow streets branching off at right angles; and its principal building is a handsome town-hall (1802). In ancient times Rutherglen was a place of much importance, a royal burgh since 1126, carrying on a large traffic on the river, and embracing great part of Glasgow within its municipal boundaries. It was the seat of a royal castle, which was captured by Edward Bruce about 1313, burned by Moray in 1568, and finally demolished in the 18th century. At Rutherglen, on 29th May 1679, the Covenanters published a 'Declaration and Testimony of the true Presbyterian Party in Scotland'—the prelude to Drumclog and Bothwell Bridge. The trade is now mainly dependent upon that of Glasgow, and its inhabitants are employed in the mills, print, chemical, tube, rope, brick and dye-works, and in the collieries. Pop. (1861) 8062; (1891) 13,361; (1921) 24,744. See Ure's *History of Rutherglen* (1793).

Ruthin, a town of Denbighshire, on the Clwyd, 8 miles SSE. of Denbigh by rail. The 13th-century castle which gave it name (Cym. *rhyf-din*, 'red fortress') surrendered in 1646 to the Roundheads, and was afterwards dismantled, part of its site being now occupied by a castellated mansion. A grammar-school, founded by Dean Goodman of Westminster in 1594, was reconstituted in 1881; and there are also an interesting collegiate church, a county hall, a corn exchange, &c. The borough was chartered by Henry VII. in 1507. Pop. (1851) 3373; (1921) 2767.

Ruthven, RAID OF, a Scottish conspiracy contrived and executed in 1582 by William, first Earl of Gowrie, father of the chief actor in the Gowrie Conspiracy (q.v.), in conjunction with Lord Lyndsay of the Byres, the Earl of Mar, and the Master of Glamis. The boy-king James VI., then under the influence of Lennox and Arran, was invited to Gowrie's seat, Castle Ruthven (pron. *Riverce*) or Huntingtower, 3 miles WNW. of Perth, to hunt; but the next morning (23d August) he found himself a prisoner in the midst of a thousand armed men. He tried to get out, but the Master of Glamis detained him, and said when he wept, 'Better bairns greet than bearded men.' Arran was thrown into prison, and Lennox retired to France, where he died broken-hearted. The Presbyterian clergy warmly espoused the cause of the Ruthven lords, who received the thanks of the General Assembly, and full indemnity from a Convention of Estates. Nearly a year elapsed before the king regained his freedom. His feigned acquiescence in his position led the confederates to relax their vigilance that, on 20th May 1583, he

was enabled to escape from Falkland to the castle of St Andrews. Gowrie and the other lords made their submission, and were pardoned; but soon afterwards a royal proclamation branded their enterprise as treason. Gowrie was commanded to leave Scotland; but in April 1584, while waiting for a vessel at Dundee, he was drawn into a conspiracy to surprise Stirling Castle, for which he was tried and executed.

Ruthwell, a Dumfriesshire coast parish, 9 miles ESE. of Dumfries. Its famous sandstone cross, 17½ feet high, bears carvings in front and behind of the Crucifixion, Annunciation, &c., with corresponding Latin inscriptions in the Roman character, and on the sides of scroll-work, with Northumbrian runic verses from 'The Dream of the Rood' (see CAEDMON and CYNEWULF). The cross, which some authorities date from the seventh century, and others from the tenth or even later, was taken down and broken in 1642 as a monument of idolatry; but in 1802 was re-erected in the manse garden by the Rev. Henry Duncan (q.v.), and in 1887 removed to an apse adjoining the church. See A. S. Cook's edition of *The Dream of the Rood* (1905); J. W. Hewison's *The Runic Roods of Ruthwell and Bewcastle* (1914); Forrest Browne's *Ancient Cross Shells at Bewcastle and Ruthwell* (1916). See also RÜNES.

Rutile (Lat. *rutillus* 'reddish'), a mineral which is essentially oxide of titanium. *Nigrine* and *Ilmenorutile* are varieties containing 2-30 per cent. of ferric oxide. It crystallises in tetragonal forms, generally as slender four-sided or six-sided prisms and needles. Now and again it occurs massive. It varies in colour from yellow to brown and red. Sometimes it presents a curious interlaced character, known as *Sagenite*. It not infrequently occurs as an endomorph in rock-crystal. As a rock-forming mineral it is not of much importance, but occurs generally as minute granules and aggregates or prismatic crystals in schistose rocks, gabbro, and other rocks. Massive rutile is used to give a yellow colour to porcelain.

Rutlam, a small Indian state in the Western Malwa Agency (see CENTRAL INDIA); pop. over 85,000. The capital, Rutlam, is a centre for grain, and has a college and other educational establishments; pop. 30,000.

Rutland, the smallest county in England, bounded by Leicester, Lincoln, and Northampton shires. It measures 18 by 15 miles, and has an area of 152 sq. m. or 97,273 acres. The Gwash or Wash, flowing to the Welland (which traces the south-east boundary), divides it into two portions—the northern a somewhat elevated tableland, while the southern consists of a number of valleys running east and west, and separated by low hills. Limestone is plentiful, and the soil is mostly a deep clay. Half the whole area is permanent pasture, the towns being Oakham and Uppingham. Rutland gives the title of duke to the family of Manners (q.v.). Its representation was reduced to one in 1885, and in 1918 it was joined to the Stamford division of Kesteven for parliamentary purposes. Pop. (1801) 16,380; (1861) 21,861; (1921) 18,368. See the 'Victoria History' (1908).

Rutland, capital of Rutland county, Vermont, is on Otter Creek, close to the Green Mountains, and 67 miles by rail SSE. of Burlington. The chief industry is the quarrying and working of marble; the place has also several foundries and railroad shops, and contains the state workhouse. From 1784 to 1804 Rutland was one of the capitals of Vermont. Pop. (1920) 14,954.

Rütli, or GRÜTLI, a meadow on the west side of the southern arm of the Lake of Lucerne, the tra-

ditional cradle of Swiss independence; here the representatives of the three cantons, Uri, Schwyz, and Unterwalden, took the oath (1307) to drive out the Austrians. It is national property, having been purchased with the pence of Swiss school-children, and is adorned with a monument (1860) to Schiller, the author of *Wilhelm Tell*, and with another (1884) in commemoration of the oath.

Ruvo in Apulia, a cathedral city of Southern Italy, 22 miles W. of Bari, with a very fine Romanesque cathedral, probably of the 13th century. Pop. 28,000.

Ruwenzori, a mountain mass in the centre of Africa, just north of the Equator, between Lakes Albert and Edward—perhaps Ptolemy's original 'Mountains of the Moon' (see MOON, MOUNTAINS OF THE). It was seen by Baker in 1871, passed by Stanley in 1888, and partly climbed by Stuhlmann, Moore, and Sir H. Johnston. In 1906 the Duke of the Abruzzi climbed sixteen chief peaks of the mass, which consists of six groups, and gave to the principal group the name of Stanley, and to its highest peaks the names Margherita (16,800 ft.) and Alexandra (16,744 ft.).

Ruysbroeck, JOHANNES, Flemish mystic, born at Ruysbroeck near Brussels in 1293, was vicar of S. Gudule's in Brussels, but in 1353 withdrew to the Augustinian monastery of Groenedael near Waterloo, and died its prior in 1381. His mysticism, mainly derived from Eckhart (q.v.), but directed in the channels of practical charity, gained for him the title of *Doctor ecstaticus*. Gerhard Groot (q.v.) was his friend. Ruysbroeck wrote in Latin and in Flemish; his works were published in Latin in 1552, and in German in 1701. See books by Engellhardt (Erlangen, 1838), Ch. Schmidt (Strasbourg, 1859), Otterloo (Amsterdam, 1874), Maestelbroeck (trans. 1894), and Evelyn Underhill (1915).

Ruysdael, or RUISDAEL, JAKOB, the greatest landscape-painter of the Dutch school, was born at Haarlem about 1628. In 1648 he was enrolled a member of the guild of St. Luke at Haarlem, and in 1659 was granted the freedom of the city of Amsterdam. He died in the almshouse of Haarlem on 14th March 1682. He loved to paint forest glades with oak-trees; sleeping pools beneath clusters of trees, with an old picturesque building, a mill or a ruined temple, or a glimpse of a distant town; a waterfall with rugged rocks, and coast scenes, where sea and earth meet. The scenes were mainly taken from the neighbourhood of Haarlem, partly from the districts of Germany that border on Holland. His work shows that he had a fine feeling for the poetic spirit of nature, which he embodies with great skill. His pictures exist in Dresden, Berlin (probably the two best collections), the Louvre, the London National Gallery, Amsterdam, and the Hague. See E. Michel, *Ruysdael et les Paysagistes d'Harlem* (Paris, 1890).

Ruyter, MICHAEL ADRIANZON (afterwards De Ruyter), Dutch admiral, was born at Flushing on 24th March 1607 of poor parents, who sent him to sea as a cabin-boy when only eleven. He changed into the navy, and by 1635 had risen to the rank of captain. From 1643 to 1652 he was again in the merchant service, and fought against the pirates of Barbary. When war broke out between England and Holland in 1652, a fleet was given to Ruyter; with it he beat off an attack made upon him (26th August) by Sir G. Aysene off the Lizard, but in conjunction with De Witt was compelled to retire after vainly attacking Blake off the mouth of the Thames (28th September). They had their revenge, however, two months later, when they defeated Blake off Dover. In the following year Ruyter took

part in the running fight in the English Channel of 18th–20th February against Blake; in that of Solebay or Southwold (2d–3d June) against Monk and Deane and Blake; in the indecisive battle off Katwyk; and in that off the Texel (29th July), in which his superior, Tromp, was killed and the Dutch fleet defeated. After this Ruyter was made vice-admiral of Holland. In 1654 peace was concluded between the two countries. In the years immediately following Ruyter was sent to blockade the coasts of Portugal, and then those of Sweden (on behalf of Denmark); he compelled the Swedes to surrender Nyborg in Finland in 1659. On the conclusion of the Dano-Swedish war (1660) the king of Denmark enrolled him. The years 1661–63 were principally occupied with checking in the Mediterranean the piracy of the Turkish states of North Africa. In 1664 war broke out again between England and Holland, and De Ruyter steered his fleet to the west coast of Africa, and took from the English Gorée and some forts on the Guinea coast: in 1665 he preyed upon English merchant-vessels in the West Indies, made his way home round Scotland, and was chosen admiral-in-chief of the Dutch fleet; in 1666 he fought for four days (June 1–4) against Monk and Prince Rupert off Dunkirk, neither side gaining the victory, though the English were the first to retire; nevertheless in July he was beaten by Monk, and driven back to Holland. In 1667 he caused great consternation in London by sailing up the Medway as far as Rochester, and burning some of the English ships, and entering the Thames a second time as high as Gravesend, besides attacking Harwich. Then came peace again; and in 1672 war once more, this time against England and France combined. De Ruyter's principal achievements in this war were to attack the English and French fleets under the Duke of York, the Earl of Sandwich, and Count d'Estrées in Solebay (28th May 1672), after which he retired to Holland; to defeat Prince Rupert and D'Estrées off Schooneveldt in June 1673, and again off Kijkduin and Helder in August. Peace was then made with England; but the war with France still went on. In the end of 1675 De Ruyter set sail for the Mediterranean, to go and help the Spaniards against the French. He encountered the French fleet under Duguesne near the Lipari Islands a few days before the New Year, and again in April in the Bay of Catania, on the east of Sicily. After the first encounter the Dutch-Spanish fleet drew off towards Palermo; in the second they were routed, and De Ruyter was seriously wounded in the right leg, the first serious wound in his life of battles. He died exactly a week later, on 29th April, in Syracuse. His body was buried in the New Church at Amsterdam. He was a man of unaffected piety, simple in his manners, and of unflinching courage; as a seaman he deserves to take rank with Blake and Nelson.

See Life (anon. Amsterdam, 1677), by Brandt (Amst. 1698), and by Richer (1783), all in French, and the English one by G. Grinnell-Milne (1897).

Ryan, LOCH, an arm of the sea, extending in a south-easterly direction into Wigtownshire from the southern entrance of the Firth of Clyde, fully 8 miles in length, with a breadth of from 1½ to almost 3 miles. From about the middle of its western side a broad sandbank called the Scar projects diagonally across it for about 2½ miles; opposite is Cairn Point with a lighthouse (1847); At its south-western corner stands the port of Stranraer, with daily steamers plying to and from Larne; two miles west of its northern extremity is Corsewall Point, a bold headland with a fine lighthouse (1816). Loch Ryan affords safe and commodious anchorage, being very deep close to its eastern shores, which are sheltered by the high

hills of Finnart and Craigcraffie, as its western are by the beautifully wooded heights of Kirkcolum and Leswalt. The *Rerigonus Sinus* of Ptolemy, Loch Ryan has been rendered classic, in name at least, by the pathetic traditional ballad, 'Fair Annie of Lochryan'—the question of its localisation is quite another matter. Hew Ainslie's spirited song, 'The Rover o' Lochryan,' deserves mention also.

Rybinsk, a town of Russia, stands on the right bank of the Volga, at the termination of a branch-line (174 miles) of the Moscow and St Petersburg Railway, and 48 miles NW. of Jaroslav. It has a very large trade in transshipping and forwarding to the capital by canal the goods brought by large vessels up the Volga. Those goods are corn, flour, tallow, spirits, metals, timber, potash, salt, &c. Boat-building, rope-making, brewing, and distilling are the chief industries. Pop. about 39,000.

Rydal Mount, Rydal Water. See LAKE DISTRICT, WORDSWORTH.

Rydberg, ABRAHAM VIKTOR, Swedish author, was born 18th December 1828 at Jönköping. After finishing at the University of Lund he turned to his pen for a living, and obtained an appointment on the staff of a Göteborg journal. While there he wrote several novels of the highest merit, among them *The Free-booter on the Baltic* (1857), *The Last of the Athenians* (1859), *Singalla* (1865). *The Armourer* followed in 1891. Rydberg became professor of Philosophy and of History of Civilisation at Göteborg, then of Fine Arts at Stockholm, and took a keen interest in biblical criticism and ecclesiastical history. He died near Stockholm 21st September 1895.

Ryde, a flourishing and fashionable holiday resort on the north-east coast of the Isle of Wight, 4½ miles SSW. of Portsmouth, from which it is separated by the roadstead of Spithead. It consists of Upper and Lower Ryde, the former occupying the site of an ancient village, *La Rye* or *La Riche*, destroyed by the French in 1377, the latter modern. Fielding in 1753 described Ryde as 'a pleasant village, separated at low-water from the sea by an impassable gulf of mud;' but now there are excellent sands, and the appearance of the town with its streets and villas interspersed with trees is pleasing and picturesque. The longer of the two piers (768 feet) was constructed in 1813-61; of the buildings may be noticed the town-hall (1831); All Saints' Church (1870), by Scott, with a spire 173 feet high; St Mary's Roman Catholic Church (1846), by Hansom; the Royal Victoria Yacht Club-house (1847); and the Royal Isle of Wight Infirmary. Ryde was made a municipal borough in 1868. Pop. (1811) 1601; (1881) 11,461; (1921) 11,294.

Rydell, LUCYAN, Polish poet and dramatist, was born in 1870. His *Magic Circle*, an historical drama, draws its inspiration from the life of the people, as does much of his poetry. Rydell can attain pleasing artistic effects.

Rye, a decayed seaport of Sussex, 11 miles NE. of Hastings, and now 2 miles inland. It stands on an eminence bounded by the Rother and the Tillingham, and presents a quaint, old-world aspect. On a rock overlooking the confluence of the streams is the 12th-century Ypres Tower, built in Stephen's reign by William de Ypres. The church, mainly Norman and Early English, one of the largest in the kingdom, was restored in 1883. Then there are the old Land Gate, a former Carmelite chapel, and a grammar-school (1638). The *Novus Portus* of Ptolemy, Rye was granted by the Confessor to Fécamp Abbey, and by Henry III. was given the privileges of the Cinque Ports (q.v.). It became a Huguenot asylum after 1562 and 1685

(Thackeray's *Denis Duval* is laid here); and it returned two members till 1832, and then one till 1885. Fletcher the dramatist was a native. Pop. 4000. See Holloway's *History of Rye* (1847).

Rye (*Secale*), a genus of grasses, allied to Wheat and Barley, and having spikes which generally consist of two-flowered, rarely of three-flowered, spikelets; the florets furnished with terminal awns, only the upper floret stalked. One species (*S. cereale*) is a well-known grain. It has, when in fruit, a roundish-quadrangular spike, with a tough rachis. Its native country, as in the case of the other most important cereals, is somewhat doubtful; but it is probably derived from *Secale montanum*, a species found wild in parts of Eastern Europe and Asia Minor. It has long been cultivated as a cereal plant; although the supposed mention of it in Exodus, ix. 32, is doubtful, spelt being perhaps intended. It is much cultivated in the north of Europe and in some parts of Asia. Its cultivation does not extend so far north as that of barley; but it grows in regions too cold for wheat, and on soils too poor and sandy for any other grain. Its ripening can also be more confidently reckoned upon in cold regions than that of any other grain. But rye succeeds best, and is most productive, in a climate where wheat still ripens. It delights in sandy soils. The varieties of rye are numerous, although much less so than those of other important cereals. Some are best fitted for sowing in autumn, others for sowing in spring. The former kinds (Winter Rye) are most extensively cultivated, being generally the most productive. In some places on the continent of Europe rye is sown at midsummer, mowed for green fodder in autumn, and left to shoot in spring, which it does at the same time with autumn-sown rye, producing a good crop of small but very mealy grain. In Britain rye is not a common grain-crop, and is cultivated to a smaller extent than it formerly was: the sandy soils, to which it is best adapted, being improved and fitted for other kinds of corn. It is, however, sometimes sown to be used as a green crop, for feeding sheep and oxen in winter, and is found particularly good for milch cows. It is sometimes also mown for horses and other animals. Bread made of rye is much used in the north of Europe; it is the familiar 'black-bread' of Germany, and the main sustenance of the Russian peasant throughout large regions. It is of a dark colour, more laxative than that made of wheat-flour, and, perhaps, rather less nutritious. In combination with other grains, rye is much used for fermentation and distillation, particularly for the making of gin. The Russian beer called *kovas* is made from rye-meal. Rye affected with Ergot (q.v.) is a very dangerous article of food. The straw of rye is tougher than that of any other corn-plant, and is much valued for straw-plait. Perennial Rye (*S. montanum*) differs from common rye in having a very hard, reed-like culm; ears, 3 to 5 inches long, flatly compressed, with a brittle rachis, and fifty to sixty closely imbricated spikelets. It endures for many years, but is not much cultivated, as its grain is slender, and does not yield an easily separable flour.

Rye-grass (*Lolium*), a genus of grasses, having a two-rowed, flatly-compressed spike, the spikelets appressed edgewise to the rachis. Perennial Rye (*L. perenne*), the *Rye-grass* of the older English authors, is frequent on waysides, and in meadows and pastures, in Britain and on the continent of Europe. The leaf is highly glazed, narrow tipped, has an obtuse ligule, surrounded by an auricle or collar-like portion of blade; whilst the younger leaves are folded throughout their

length on the midrib when emerging from the purple sheath. The spikelets are much longer than their solitary external glume, six to eight flowered; the florets awnless or nearly so; the culm flattened, from 1 foot to 2 feet high; the root

Fig. 1. —Perennial Rye-grass (*Lolium perenne*) in flower, showing united root tufts: a, a spikelet in flower.

producing leafy barren shoots, which add much to the agricultural value of the grass. This grass is highly valued for forage and hay, and is more extensively sown for these uses than any other grass, not only in Britain, but also on the continent of Europe and in North America. It grows well even on very poor soils. The *Pavonia* Rye is the kind most generally cultivated. A number of years ago there was much discussion in England as to whether or not Rye-grass is really perennial. It is admitted to be of short duration

Fig. 2. —Italian Rye-grass (*Lolium italicum*) in flower: a, spikelet in flower.

grass, and is preferred by cattle to the perennial rye-grass. The florets are awned, and the plant biennial. In many soils and situations in Britain

succeeds extremely well, and is remarkable for its verdure and luxuriance in early spring. There are many varieties of rye-grass. It is nowhere so much valued or cultivated as in Britain, and was grown as a crop in England before the end of the 17th century. Rye, along with other grass seeds and the seeds of clovers, is generally sown along with some kind of corn, and, vegetating for the first year amongst the corn, appears in the second year with the other grasses and clovers as the proper crop of the field. See Stebler and Schröter, *The Best Forage Plants* (Eng. trans. by M'Alpine, 1889), from which our illustrations are copied.

Rye-house Plot. In 1682-83, whilst a scheme was formed among the leading Whigs to raise the nation in arms against Charles II., a subordinate scheme was planned by a few fierce spirits of the party—including Colonel Rumsey and Lieutenant-colonel Walcott, two military adventurers; Good-enough, under-sheriff of London; Ferguson, 'the Plotter'; and several attorneys, merchants, and tradesmen of London—the object of which was to waylay and assassinate the king on his return from Newmarket. The deed was to be perpetrated at a farm near Hertford, belonging to Rumbold, one of the conspirators, called Rye-house, whence the plot got its name. The Rye-house Plot is supposed to have been kept concealed from Monmouth, Russell, Shaftesbury, and the rest of those who took the lead in the greater conspiracy. It owed its defeat to the circumstance that the house which the king occupied at Newmarket took fire accidentally, and Charles was thus obliged to leave that place eight days sooner than 22d March. Both the greater and lesser conspiracy were discovered before long, and from the connection subsisting between the two it was difficult altogether to dis sever them. The indignation excited by the Rye-house Plot was extended to the whole Whig party; Russell, Algernon Sidney, and Walcott were brought to the block for treason; John Hampden, grandson of the patriot, was fined £40,000; and scarcely one escaped who had been concerned in either plot. See *Ferguson the Plotter*, by J. Ferguson (1887).

Ryle, JOHN CHARLES, Bishop of Liverpool, was born at Macclesfield, May 10, 1818, studied at Christ Church, Oxford, carried off the Craven Scholarship, and graduated with a classical first-class in 1837. He was successively curate at Exbury, Hants; rector of St Thomas's, Winchester (1843); of Helmingham, Suffolk (1844); vicar of Stradbroke, Suffolk (1861); select preacher at Cambridge (1873-74), and at Oxford (1874-76). In 1880 he was nominated by Beaconsfield Dean of Salisbury, and before taking possession was raised to the new see of Liverpool. A prominent Evangelical, he wrote, besides countless tracts of vast popularity, *Coming Events and Present Duties* (1867), *The Christian Leaders of the Last Century* (1869), and *Expository Thoughts on the Gospels* (7 vols. 1856-69). He died at Lowestoft, 10th June 1900. —His second son, HERBERT, born in London, 25th May 1856, was Bishop of Exeter (1901-3), Bishop of Winchester (1903-11), and Dean of Westminster from 1911 till his death, 20th August 1925. He was the author of several theological works.

Rymer, THOMAS, compiler of the *Fæderæ*, was born at Northallerton in 1639, studied at Sidney Sussex College, Cambridge, and entered at Gray's Inn in 1666. He published translations, critical discussions on poetry, dramas of his own, and works on history, and was appointed historiographer royal; but he died in poverty, 14th December 1714. Pope considered him 'one of the best critics we ever had'; Macaulay 'the worst critic

that ever lived'—both rather overstating the case. His principal critical work is *The Tragedies of the Last Age Considered* (1678); but he is chiefly remembered as the compiler of the invaluable collection of historical materials called *Fœdera, Conventiones, Litteræ et cujuscunque generis Acta Publica inter Reges Angliæ et alios quosvis Imperatores, Reges, Pontifices, Principes vel Communitates*, extending from the 11th century to his own time. Vols. i.-xv. were published before Rymer's death; vols. xvi.-xx. by his assistant, Sanderson, in 1715-35; Tonson's reprint of the first 17 vols. in 1727-29; the Hague edition in 1737-45; that (incomplete, 3 vols.) of the Record Commission in 1816-69; and Sir Thomas Hardy's *Syllabus* of the whole, in 3 vols., in 1869-85.

Rymour. See THOMAS THE RHYMER.

Ryot. See INDIA, Vol. VI. p. 113.

Rysbrach. MICHAEL, sculptor, born at Antwerp on 24th June 1693, settled in London in 1720, and executed numerous works, in particular the monument to Sir Isaac Newton in Westminster Abbey (1731), that to the Duke and Duchess of Marlborough at Blenheim, a bronze equestrian statue of William III. for Bristol (1733), a colossal statue of George II. for the parade at Greenwich Hospital (1735), a Hercules at Stonhead, a statue of Queen Anne at Blenheim, one of Locke in Christ Church, Oxford (1757), and busts of Admiral Vernon, Earl Stanhope, Kueller, Gay, Rowe, Milton, Ben Jonson, Palladio, Inigo Jones, the Dukes of Somerset, Beaufort, and Argyll, Sir Hans Sloane, Pope, Sir R. Walpole, Bolingbroke, &c. He died 8th January 1770.

Ryswick. PEACE OF, was signed at Ryswick, a Dutch village, 2 miles S. of the Hague, by France, England, the Netherlands, and Spain, on September 20, and by Germany on October 30, 1697. It wound up the sanguinary contest in which England

and her allies had been engaged with France, by putting an effectual check upon the power and overweening ambition of France.

Rytina. See RHYTINA.

Ryūkyū (otherwise *Linkein* or *Luchu*), a group of fifty-five islands, of which the most considerable are Oshima and Okinawa. The islands extend at irregular intervals in a south-westerly direction from Kyūshū in Japan, and form the prefecture of Okinawa in that empire. Their aggregate area is about 1000 sq. m., and the population amounts to about 472,000. Linguistically and ethnically the Ryūkyūans, though there is an Ainu element, are similar to the Japanese, and their manners, customs, and religious observances (Shintōist) bear a close affinity. They were formerly subject to the lord of Satsuma, and paid an annual tribute, having been completely subjected in 1609. China made a claim upon the islands, but they are now an undisputed possession of Japan. The men do not shave the hair like the Japanese; they pin it on the crown of the head, with a star in front. The women tattoo their hands. The streets are paved with stone, and stone walls ten or twelve feet high, giving the streets a desolate appearance, enclose the houses, which are similar in structure and arrangements to Japanese houses; the tiles used for roofing, however, are not black, but red in colour. There are no shops in Ryūkyū, only a market-place in each town. The food of the people consists principally of sweet potatoes, pork, and fish, a pig being usually kept by each family. Oshima possesses a good harbour, but Naha, the port of Shinri, capital of Okinawa, is an unsafe anchorage. Sugar is largely raised, also a so-called sago, and an aromatic variety of orange; the coco-nut palms do not seem to yield fruit. A small breed of ponies is found on the islands.

S

the nineteenth letter of our alphabet, represents historically the twenty-first letter of the ancient Semitic alphabet, which in Hebrew and Syriac has the sound not of *s* but of *sh*. It is to be observed, however, that the primitive phonetic value of the letter is somewhat uncertain;

the Hebrew *sh* for the most part corresponds etymologically to the Arabic *s*, and *vice versa*. It is therefore possible that in the particular Semitic dialect of the people from whom the Greeks learned the alphabet the twenty-first letter may have been pronounced as *s*, and the fifteenth letter (Hebrew *sāmekh*, Syriac *semkath*, the original of the Greek Ξ and the Roman X) may have been pronounced as *sh*. According to the tradition represented by the Masoretic punctuation, the twenty-first letter had exceptionally the sound of *s* in a certain number of words, in which it corresponds etymologically to the Syriac *s* (the fifteenth letter) and the Arabic *sh*. The story in Judges relating to the pronunciation of the word *shibboleth* shows that one Hebrew dialect either confused the two sounds or reversed their respective functions, as in Arabic.

The name of the letter is in Hebrew and Syriac *shin*; a variant Hebrew pronunciation *shen* is indicated by the transliteration שֶׁן (*shsen*) in the Vatican Septuagint. There is little doubt that the name is an alteration of the Semitic word for tooth, in Hebrew *shēn* (plural *shinnim*). The earliest known form of the letter, *w*, may have originated from a zigzag representing teeth. The form is approximately preserved in the Hebrew

ש. In the Arabic alphabet س, named *sīn*, stands for *s*, and ش, *shīn*, for *sh*.

The Greeks adopted the letter with the value of *s*. Its early Greek forms are Σ and Ϻ; the former became general in the East, and is represented by Σ in printed Greek, while the latter was carried into Italy, and was developed into the Roman S. In the uncial Greek script, which preferred rounded outlines, Σ became Ϛ. The Greek name of the letter, *sigma*, is a verbal noun derived from *seizein*, to hiss; but some think it was suggested by the name of the fifteenth Semitic letter (in Hebrew *sāmekh*: see the article X). In the early Greek alphabet the sound of *s* was represented by two different characters, the sigma and Μ, called *san*, which stood in the eighteenth place between *pi* and *koppa*. This was an adoption of the eighteenth Semitic letter (called in Hebrew *šāthēr*), by which was represented a peculiar variety of *s* sound, not used in Greek. In the later Greek alphabet *san* was omitted, so that the following *koppa* became the eighteenth letter, and was consequently used as the numerical symbol for 90. A character composed of *san* and *pi*, called *sampi*, and written Ϟ, was used as a symbol for 80, though Ι (*pi*) was also employed for this purpose. The Roman S is not well suited for rapid writing; script it

upright or sloping line. From this was developed

the Hiberno-Saxon J, and various mediæval minuscule forms, among which are those represented by the German printed f and the nearly obsolete roman and italic f, f. The original form was, however, also preserved, both as capital and minuscule, and was further developed into a great variety of shapes. As a capital, it was often disguised by calligraphic flourishes; the German printed S represents one of the common 15th-century MS. forms. English printers continued to use the 'long f,' in other than final positions, until the beginning of the 19th century; but as it has an inconvenient likeness to f, it has wisely been discarded.

In classical Latin S was always pronounced as the voiceless sibilant in *so*, *speak*; and this is its normal value in all the modern languages except Hungarian, where *s* has the sound of *sh* and *sz* that of *s*. In Late Latin this sound became voiced (: English *z*) when between vowels, and as the change of pronunciation was not indicated in writing, the letter S is under certain conditions sounded as *z* in most of the languages written in the Roman alphabet: in French and (usually) in Italian between vowels; in German before a vowel; in English no comprehensive rule can be given, but initial *s* is always voiceless. In Spanish the voiced *s* and does not exist, and in Dutch it is consistently written Z, so that in these languages S has always its normal value. In some English words, where the spelling represents an obsolete pronunciation, the letter has the sound of *sh* (e.g. in *sugar*, *sare*) or *zh* (e.g. in *vision*, *pleasure*).

In several languages the letter forms part of a compound symbol for the simple consonant-sound *sh*. This sound often represents an earlier *sh*; hence in late Old English it was written *sc*, in Italian it is written *sc* before *e* and *i*, and *sci* before other vowels; in German *sch* (Old High German *sc*). Our modern English *sh*, which dates from about 1200 A.D., is a simplification of *sch*, which survived in occasional use till the 16th century (in Scotland still later). Other notations for this sound are the Polish *sz* and the Bohemian *š*. The Latin name of the letter *es* (for the origin of which see the article F) is preserved in the modern languages, but has become disyllabic in Italian (*esse*) and Spanish (*ese*).

Saadi. See SADI.

Saale, a river of Germany, distinguished from smaller rivers of the same name as the Saxon or Thuringian Saale, rises on the western slope of the Fichtelgebirge (Bavaria), and, flowing northward past the towns of Hof, Rudolstadt, Jena, Naumburg, Weissenfels, Merseburg, and Halle, falls into the Elbe, about 18 miles above Magdeburg, after a course of 226 miles.

Saalfeld, a town of Thuringia, on the Saale, 31 miles by rail SSW. of Jena, has ruins of a castle built by Charlemagne against the Sorbs, and graphite, machinery, and other works. Pop. 18,000.

Saar (Fr. *Sarre*), a river of Lorraine and Prussia, flows 150 NNW. from the Vosges to the

Moselle above Trier. On it stand Saarburg (Saarebourg), Saargemünd, Saarbrücken, Saarlouis, and another Saarburg.—The SAARGEBIET, a region of Prussia and Bavaria in the Saar basin, rich in coal and iron, was placed by the treaty of Versailles under a commission representing the League of Nations, the mines to be exploited by France, until 1935, when the people are to choose between Germany and France or continue the international government. Area, 744 sq. m. (574 in Prussia); pop. (1922), 713,105 (622,418 in Prussia); chief towns, Saarbrücken, Neunkirchen, Völklingen, Sulzbach.

Saarbrücken, a town of Rheinland (Saargebiet), on the Saar, 40 miles SE. of Trier, is the centre of a large coalfield, and of iron and glass works, with manufactures of tobacco, chemicals, metal utensils, &c. Here, on 2d August 1870, the first engagement took place between the French and Germans, the latter retreating. Pop. 125,000.

Saardam. See ZAANDAM.

Saare-Maa. See OESSEL.

Saargemünd (Fr. *Sarreguemines*), a town in Alsace-Lorraine (Département of Moselle). It is 41 miles E. of Metz, and is famous for its pottery; silk plush and velvet are also made. Pop. 14,000.

Saarlouis, a former fortress of Rhenish Prussia (Saargebiet), 31 miles S. of Trier, on the left bank of the Saar. Fortified (1681–85) by Vauban, it was in the possession of France until 1815, when the Congress of Vienna gave it to Prussia. Here Marshal Ney was born. Pop. 16,000.

Saaz, a town of Bohemia, on the Eger, 66 miles by rail NW. of Prague. Pop. 16,000, principally engaged in growing and trading in hops, and in manufacturing sugar, leather, &c.

Saba, a Dutch West Indian island, in the Leeward group, 40 miles NW. of St Kitts. A volcanic cone, 1500 feet high, it is known from its shape as 'Napoleon's cocked hat.' Area, 5 sq. m.

Saba'. See SABEANS, SHEBA, YEMEN.

Sabac, or SHABATZ, a town of Serbia, on the Save, 38 miles W. of Belgrade. Pop. 9000.

Sabadell, a town of Spain, 14 miles by railway NW. of Barcelona. It has risen into importance only within recent years, and is the Manchester of Catalonia. Cotton and woollen fabrics are the staple manufactures. Pop. (1921) 37,529.

Sabadilla, CEBADILLA, or CEVADILLA, the dried ripe seeds of the *Schamocaulon officinale* (Liliaceae), formerly official in the British Pharmacopœia, but now little used, containing an alkaloid, veratrine, and other closely allied substances. When applied externally the powdered sabadilla or veratrine is first irritant and then anæsthetic; both forms are used in rheumatic and neuralgic pains. Snuffed into the nostrils they cause violent sneezing and irritation. Taken by the mouth they are also irritant, if in too large a dose, and induce pain, vomiting, and diarrhoea. After absorption into the blood in medicinal doses they act chiefly on the muscles, and depress the heart and circulation and the body temperature. They have been employed in acute febrile diseases in strong, healthy persons, but must be used with great caution on account of their marked depressant effects. The dose of veratrine is $\frac{1}{16}$ to $\frac{1}{8}$ grain.

Sabeans, or SABA', were the ancient inhabitants of Yemen in southern Arabia. They are the people called Sheba in Gen. x. 28, xxv. 3; Job, vi. 19; and other passages in the prophets; and it was probably the sovereign of this people who paid the celebrated visit to Solomon. The Sabeans were a powerful and wealthy people, who from long before

the days of Solomon down to the beginning of the Christian era controlled the sea and caravan traffic in gold, sweet spices, ivory, ebony, and valuable tissues, that came from India and Africa, and were despatched northwards to Syria. To protect and watch over this trade they had stations or colonies in northern Arabia and in Ethiopia. The capital of their country was Mariaba (Marib), the ruins of which, including vast dams, lie north-east of Sanaa (q.v.). Their religion included the worship of the sun and moon, and a number of other deities. Their language is intermediate between Arabic and Ethiopian, but nearer akin to the former. In the 8th century B.C. the people of Saba' paid tribute to the kings of Assyria (Tiglath-Pileser and Sargon). The Roman governor of Egypt in 24 B.C., tempted by the fame of the great wealth of the Sabeans, sent an expedition under command of Aelius Gallus to invade their country; but it met with little success. Not long after this event, however, the trade upon which the Sabeans relied began to take a sea-route and go up the Red Sea, and from that cause their prosperity and power seem to have declined. Soon afterwards they appear to have been subject to the sovereignty of the king of the Himyarites. Then, in the 2d century, and again in the 4th, and yet again in the 6th, we read that kings of Ethiopia were lords over the Sabeans. See SEMITES; and the various works by D. H. Müller, Glaser, O. Weber, and especially Ditlef Nielsen.

Sabah, a name for British North Borneo. See BORNEO, and SANDAKAN.

Sabal, a South American and West Indian genus of Palms, known as Palmetto. See PALM.

Sabbatai Zevi (also spelt *Sabbathais Zevi* and *Sabtai Zefi*), a messiah, the founder of a wide-spread sect of semi-Christians and semi-Jews throughout Europe, Asia, and Africa, was born at Smyrna in 1641. By his personal magnetism, his character, his extraordinary learning, and his brilliant abilities, he led thousands of followers, mainly in Smyrna, Salonica, Alexandria, and Jerusalem, where he successively laboured, to believe in him as the Messiah (see MAHDI). In 1664 no fewer than about 80,000 people belonged to the new empire; and in the following year the beginning of the Messianic reign within a few months and the rebuilding of the Temple in the next year were proclaimed aloud in the streets of Alexandria by Sabbatai and six disciples, all clad in white raiments, with garlands on their heads. Somewhat later he returned to Jerusalem; and the general resurrection, to take place within six years, and the deposition of the sultan, whose crown would be placed upon Sabbatai's head, were proclaimed far and near. But three years later, having provoked serious alarm at Constantinople, he was apprehended at Smyrna, and terrified into something like a renunciation of his mission. He was said to have declared that his sole object had been all along to embrace Islam, and to carry over all the Jews with him. The sultan declared himself satisfied, and honoured him with the title of an effendi, giving him an honorary post at the same time. But the movement was far from having reached its end. A fictitious man was supposed by some to have embraced Islam, while the real Messiah had ascended heavenwards. Finally the grand vizier was persuaded to imprison Sabbatai once more, and to send him to Albania or Serbia, where he died in prison—according to some, in consequence of poison, while according to others he was executed in 1677, ten years after his conversion.

Sabbath. The etymology of the Hebrew word *shabbath*, from which the English *Sabbath*, *Gr. sabbaton* are derived, is doubtful, the verb *shabath*

(he rested) and the numeral *shivah* (seven) possessing equal claims and difficulties. For the etymology see the references in the Oxf. Heb. *Lexicon* (F. Brown, S. R. Driver, and C. A. Briggs, Oxf. 1896 *et seq.*), *s.v.*, and H. Hirschfeld (in *J.R.A.S.* April 1896, pp. 353 foll.). In any case, the seventh day of the week, set aside, in the Old Testament, as a period of cessation from work. When it was instituted is not known. Many have contended that from its moral and religious importance it must have been instituted at the Creation, and made binding on Adam in paradise and all his posterity. There is certainly no evidence in the Pentateuch of its having been kept in patriarchal times. The celebration of the seventh day is first mentioned after the Exodus from Egypt; though the circumstances connected with the gathering of quails recorded in Ex. xvi. 23 is sometimes held to presuppose the solemnisation of the Sabbath before the Sinaitic legislation (Ex. xx.); and the formula 'Remember' with which the commandment begins has been interpreted as implying that it was known before, and only required to be emphatically recalled to memory. The reason given for the observance in Ex. xx. 11 cannot be taken as deciding the point; for the reason appended to the fourth commandment in Deut. v. 15 is wholly different.

The weekly division of time was of course in no way peculiar to the Jews (see WEEK), nor was the religious solemnisation of the seventh day. As we learn from Sayce (*Ancient Empires of the East*), 'in Babylonia and Assyria the week of seven days was an Accadian or Babylonian invention, the days of the week being dedicated to the moon, sun, and five planets. The 7th, 14th, 21st, and 28th days of the lunar month were kept like the Jewish Sabbath, and were actually so named in Assyrian. They were termed *dies nefasti* in Accadian, rendered "days of completion (of labour)" in Assyrian; the Assyrian *Sabbatu* or "Sabbath" itself being further defined as meaning "completion of work" and "a day of rest for the soul." In those days it was forbidden, at all events in the Accadian period, to cook food, to change one's dress or wear white robes, to offer sacrifice, to ride in a chariot, to legislate, to practise augury, or even to use medicine.' The functions of the Babylonian Sabbath and its relations to the Hebrew day of rest are discussed by T. G. Pinches (Hastings, *E.R.E.*, *s.v.*).

But it was the Jewish Sabbath that left its mark on the religious history of the world. Even on the traditional view of the date and origin of the several parts of the Pentateuch and the Old Testament, it seems obvious that, whatever may have been the date of its institution, the laws and customs regulating its observance grew greatly in detail and in strictness. But if the Deuteronomic and priestly legislation (see BIBLE, PENTATEUCH) be regarded as much later than the Jehovist documents, the gradual development in stringency of the Sabbath ordinances becomes still more patent. Wellhausen and his school hold that new moon and Sabbaths were originally lunar festivals, regulated by the phases of the moon; and that, although there is little about the new moon in the Pentateuch, it originally stood on a somewhat similar footing with the Sabbaths, and was celebrated in the same manner (see Amos, viii. 5; 2 Kings, iv. 22, 23)—viz. with such rest from labour as was the natural accompaniment of a festival, a festival, too, originally marked even by mirth (Hosea, ii. 13). The new-moon feast was probably allowed to fall into desuetude as being so constantly associated with idolatrous and unholy rites by the heathen. The Jehovist and the Deuteronomist in dealing with the Sabbath have chiefly agricultural labour in their eye: the masters who can rest when they will are not commanded to rest themselves, but to let their

servants and cattle rest. But in the priestly legislation the Sabbath is less of a festival and more of an ascetic observance, rest being inculcated in and for itself, not as relief and refreshment from toil, but as a kind of offering to God; a pious duty of self-restraint and self-repression as incumbent on master as on man. To go out of the camp to gather manna or wood is a transgression: it is Sabbath-breaking to kindle a fire or cook food (Ex. xxxv. 2, 3; xvi. 23). Jeremiah is the earliest of the prophets to insist on stricter Sabbath-keeping, followed by Ezekiel and the Deutero-Isaiah. During the Captivity the Sabbath was wholly separated from the sacrificial service of the festival, and increased in significance as a holy rest-day, becoming along with circumcision the mark of the Jew as distinguished from the Gentile. The builders of the second temple had a severe struggle to secure the strict sanctification of the seventh day; but as the pharisaical party increased in power the day became more and more burdensome—the rest of the week was but a preparation for the Sabbath, so that man seemed to be made for the Sabbath. When Jerusalem was stormed by Ptolemy I, the inhabitants would not stir in self-defence; those who had fled to escape the persecution of Antiochus Epiphanes allowed themselves to be butchered wholesale rather than resist on the holy day. Both Pompey and Titus seem to have made arrangements for attacking Jerusalem, relying on the strict observance of the day by the Jews. There are, however, cases during the Maccabean period of Jewish armies not merely defending themselves, but making fierce attacks. The Mishna enumerates thirty-nine principal works which are forbidden on Sabbath; and to each of them are attached several minor ones which might lead to Sabbath-breaking. The 'Sabbath-day's journey'—the prohibition of walking more than the 2000 yards supposed to represent the distance between the ark and the end of the camp—seems to belong to Roman times. The Essenes were specially strict in their Sabbath-keeping.

On Sabbath the faithful assembled in the synagogue in every town and hamlet within and without Palestine, especially after the exile. Parts of the Pentateuch and of the Prophets were read, translated into the vernacular, and expounded. Special prayers were said and sung, and the rest of the day was devoted to pious meditation, study of the law, and serene joyfulness. For even in the later Jewish period the Sabbath was still distinctly a festival, 'a day of joy and delight.' Fasting, mourning, and self-mortification were expressly prohibited. The day was to be honoured by wearing of finer garments, by taking of three meals of the best cheer available (though not of freshly-cooked viands), accompanied with wine. The Karaites alone abstained from all fire and light for twenty-four hours. It should be added that by the Jews the Sabbath is reckoned from Friday evening to Saturday evening.

The analogy of the weekly Sabbath helped doubtless to mould the observance of a *Sabbatical Year*, which was apparently kept with strictness after the exile, though unknown to the early legislation. It was indeed enjoined that Hebrew slaves should be set free in the seventh year (Ex. xxi. 2-6), and that the seventh-year's crop should be left for the poor (Ex. xxiii. 10). But there is no hint that the seventh years coincided for any two persons or places: still less, that one Sabbath-year was held by the whole nation at the same time once in seven years. But after the Exile a periodic time was fairly established, the fields were left absolutely fallow, and no crops sown or harvested, to the severe suffering of many in evil times.

For a further study of the Jewish Sabbath the following works may be consulted, the literature, naturally, being vast. Reference should be made to the articles in the *Jew. Encyc.* and Hastings's *E.R.E.*, the text-books of the Jewish religion, e.g., M. Friedländer, *Jew. Rel.* (Lond. 1900); or M. Joseph, *Jud. us Creed and Life* (Lond. 1903). L. Goldschmidt's annotated and critical German version of the talmudical tractate *Sabbath* (Berlin, 1897 *et seq.*) is superior to the English versions of Rodkinson (New York, 1902 *et seq.*) or W. Wotton (Lond. 1878, *Mishnah* only), but the beginner will be unable unaided to evaluate talmudical evidence accurately. For certain mediæval Jewish writers translations may more usefully be consulted, e.g. Judah ha-Levi, *Khazari* (Eng. trans. H. Hirschfeld, Lond. 1905; see pp. 92 foll.); Maimonides, *Guide to the Perplexed* (Eng. trans. M. Friedländer, Lond. 1910). See I. Abrahams, *Jewish Life in the Middle Ages*, chap. xxi. &c., (Lond. 1896); W. O. E. Oosterley and C. H. Box, *Relig. and Wor. of the Syn.* (Lond. 1911). The Jewish novels of Zangwill, Gordon, Trager, &c., give an insight into Jewish life on the Sabbath. For English versions of the Sabbath liturgy, see the various translations by Singer, Gaster, Davis and Adler, D. Levi, Valentine, Mendes, &c. The Sabbath table songs have been rendered into German verse by L. Hirschfeld (Mainz, n.d.), and into English verse (selections) by Mrs Lucas, Mrs Salaman, and H. Loewe.

Christ and the apostles nowhere enjoin the observance of the Sabbath, but did themselves observe it, though acting on the principle that the 'Sabbath was made for man, and not man for the Sabbath,' and that 'the Son of man was lord also of the Sabbath.' Christ came into collision with the Pharisaic worshippers of the letter, and was more than once in danger of his life as a Sabbath-breaker. Even after the death of Christ there is no formal abrogation of the Sabbath; the apostles seem still themselves to have kept it in the Jewish manner. But its observance was not merely not enjoined on Christian proselytes: Paul most energetically insists that Gentile Christians should hold themselves absolutely free to observe it or not as seemed best. There were, however, Judaisers in the Christian church, whom Paul resisted; and the Ebionites (q.v.) insisted on the keeping of the Sabbath.

Nor is there anywhere in the New Testament any express statement that the first day of the week was to be kept in place of the seventh, or that the Lord's day represented or was in any way the Sabbath; though at a very early date Christians met for worship on the day on which Christ rose from the dead. The only mention of a Christian Sabbath in the New Testament is Heb. iv. 9: 'There remaineth therefore a Sabbath rest for the people of God' (New Translation), where obviously the reference is not to any one day of seven. A large body of Christians maintain that with the death of Christ the seventh-day Sabbath ceased for Christians, and that (apart from what Jewish Christians might have felt it their duty to do in the way of keeping the seventh day) the first day or Christian Sabbath naturally and inevitably took its place. Without citing any explicit authority for the substitution, they insist that the fourth commandment was a perpetual obligation as regards keeping holy one day in seven, and that the early Christian church could have no difficulty or hesitation in accepting at once the guidance of Providence in transferring the religious significance of the Sabbath of the law to the Sabbath of the new covenant; and that the Christian Sabbath has ever since continued, and to the end of the world will continue, obligatory on all Christians, all that was essentially moral and religious in the Jewish observances being applicable to the first day.

It must certainly be admitted that the earliest Christian writers do not identify the Sabbath and the Lord's day; none of the Fathers before the 4th

century ground the duty of observing Sunday on the fourth commandment, or on the precept or example of Jesus or the apostles, or on an ante-Mosaic law promulgated at the Creation. Justin Martyr speaks of the regular assemblies of Christians on Sunday, 'because it is the first day in which God changed darkness and matter and made the world. On the same day also Jesus Christ our Saviour rose from the dead.' He makes no mention of abstinence from labour as part of the observance of the day. But whatever may have been the opinion and practice of these early Christians in regard to cessation from labour on the Sunday, unquestionably the first law, either ecclesiastical or civil, by which the sabbatical observance of that day is known to have been ordained, is the edict of Constantine, 321 A.D., of which the following is a translation: 'Let all judges, inhabitants of the cities, and artificers rest on the venerable day of the sun. But in the country husbandmen may freely and lawfully apply to the business of agriculture; since it often happens that the sowing of corn and planting of vines cannot be so advantageously performed on any other day; lest, by neglecting the opportunity, they should lose the benefits which the divine bounty bestows on us.' Before this time, such of the Christian writers as had endeavoured, by a mystical style of interpretation, to turn the Mosaic ceremonies to account as sources of moral and religious instruction had, probably in imitation of Philo, spiritualised the law of the Sabbath to the effect of representing it as a mystical prohibition to the Christian of evil works during all the days of his life, and a prefiguration of the spiritual repose and enjoyment which is his portion both in this world and in the next. But, in addition to this significance, there now began to be discovered in the Old Testament foreshadowings of the new Sunday-Sabbath; and the decrees of synods became more stringent. The Emperor Theodosius forbade business and public spectacles; Leo III. forbade legal processes and all labour. The Frank kings enforced Sunday observance by severe statutes. In England Ina of Essex forbade all servile work, and Alfred all labour, traffic, and legal processes. Chut was a supporter of Sunday observance; and some of the Norman kings were more strenuous. Statutes of Edward III., Richard II., and Edward IV. specially deal with the subject.

In Scotland the first record of effort by the authorities for the sanctification of the Lord's day is in the life of St Margaret. That saintly and most influential promoter of the stricter Roman usages had in Scotland to contend with great regardlessness of the Sunday, the Culdees (whom strangely enough Presbyterians were wont to claim as their spiritual ancestors) championing a lax Sunday keeping. 'It was another custom of theirs to neglect the reverence due to the Lord's day, by devoting themselves to every kind of business upon it just as they do on other days. That this was contrary to the law she proved to them by reason as well as by authority. Let us venerate the Lord's day because of the resurrection of the Lord, which happened that day, and let us no longer do servile works upon it.' She further quoted St Gregory's arguments in favour of keeping holy the day, and proved so unanswerable that thenceforward no one ventured to carry burdens or compel another to do so. How long the influence of St Margaret continued we do not know. Her descendant, James IV., seems to have paid more attention to the fourth commandment than to some of the others; Pedro de Ayala records of him that he 'fears God and observes all the precepts of the church. He does not eat meat on Wednesdays or Fridays. He would not ride on Sundays for any

consideration, not even to mass.' But in Scotland, as a rule, the pre-reformation Sunday was in no sense strict; markets and fairs were commonly held on that day. Archery was practised; and Robin Hood and Little John plays were special Sunday spectacles.

The continental Reformers, while insisting on the value of Sunday as a day of rest and worship, favoured the 'Dominical' as distinguished from the 'Puritan' view of Sunday. Luther denied that Sunday should be kept because Moses commanded it; Zwingli is even more explicit; the second Helvetic Confession (1566) denies that keeping one day in seven is a moral duty, or that the observance of Sunday is founded on the fourth commandment, or that the Christian people might not choose any other day than the first; Calvin supports the freer view; and Beza expressly says that 'a Judicial rest from all kinds of work is not to be observed.' Nowhere except in English-speaking countries is the name Sabbath connected with Sunday; when the word is regularly used for the name of a day of the week, as in Italian (*Sabbato*), it simply means Saturday; the word for Sunday being with the Romance-speaking peoples derived from the Latin *dies dominica* ('Lord's day')—*Doménica, Dimanche*, &c.

The English reformers—Cranmer, Hooper, Frith, Tyndale—it may generally be said, took a view distinctly unlike that of the Puritans. In Scotland also the less strict opinion at first prevailed. Knox's *Confession* and the Geneva Catechism, in use till the Westminster Confession was adopted, do not insist even on Sunday observances, and the word Sabbath is not used. Knox wrote letters and entertained guests to dinner on Sunday; plays (religious subjects) were performed on Sundays with the sanction of kirk-sessions as late as 1574. Church acts were immediately passed against holding markets on Sunday (a custom which obtained, in some places at least, as late as 1581), or producing the play of Robin Hood, and drinking in taverns in time of sermon. The Sunday is called Saboth-day soon after the Reformation; and the national legislation against all working or trading on Sunday dates from the Act of 1579. But it is contended, on good grounds, that the stricter view of Sabbath observance is of Puritan origin, and was introduced into Scotland from England. Some Puritans called the Lord's day 'the Sabbath' long before the end of the 16th century; but the first full statement of the 'high' doctrine of the Christian Sabbath was the *Sabbathum Veteris et Novi Testamenti: or the True Doctrine of the Sabbath*, by Dr Nicolas Bownde or Bound (1st ed. 1593; enlarged ed. 1606). The observance of the Sunday now became a keenly debated point between Puritans and High Churchmen—the first question of doctrine on which they directly differed. The Book of Sports (see SPORTS, BOOK OF) was long an apple of discord between Puritans and the other party; in the Long Parliament the Puritans triumphed, and the Westminster Assembly incorporated the Puritan view. It is certainly after the date of Bownde that the kirk-session records of Scotland are filled with proceedings against Sabbath-breakers for all manner of work, indoor and outdoor (shaving being especially noted), walking or 'vaging' in the streets and fields, being absent from public worship, &c., as well as for drinking or really disorderly and disquieting conduct. Sabbath-breaking was one of the charges on which the bishops were deposed by the Covenanted General Assembly of 1638. Scotland has since then been specially the classical land of Sabbath observance, though the early legislation of Massachusetts and Connecticut (where it was ordained that Sunday should be counted from sunset on Saturday) was

even more puritanically rigorous. But in Scotland, as in England and America, the tendency is towards giving greater freedom to the individual conscience. Still, great numbers of devout Christians regret this tendency, and press for greater strictness of observance, and seek legislative support. In Scotland public-houses have been strictly kept closed since 1853; in Ireland, with exception of the great towns, since 1878; and in Wales since 1881; but English Sunday Closing Bills have always been negatived. In Scotland especially there used to be frequent agitation against Sunday trains, Sunday postal deliveries, the opening of museums, libraries, or botanic gardens, and Sunday cycling; and disasters such as that of the Tay Bridge (1879) were by some treated publicly as God's judgment on Sabbath-breaking. The Sabbath Alliance was founded in 1847 for promoting the stricter observance of Sunday. On the other hand, the Sunday Society was founded in 1875, under the auspices of Dean Stanley and others, to secure the opening of museums and galleries on Sunday. The Grosvenor Gallery was opened on Sunday in 1878; the same year the Manchester and some others were opened on Sunday for the first time. The question as to Sunday trains, long fiercely debated in America, was compromised by allowing the running of the through mails, while, as in England, local trains do not usually run.

The law of England on Sunday observance begins with acts of Charles I. (1625 and 1627), but is mainly based on the Act 29 Car. II. chap. 7, dating from 1676, which forbids all labour, business, or work done in the course of a man's calling on the Lord's day, works of necessity and mercy being excepted. It does not apply to coach-hirers, or drivers, or farmers. A baker baking bread transgresses the statute, but not one who bakes his customers' Sunday dinners. Contracts entered into on Sunday are not void if they are not within the regular business of the contracting parties; a tradesman may draw or accept a bill of exchange on Sunday, and a professional man may sell his horse. By an act of Geo. III. any house of amusement to which persons are admitted on a Sunday on paying money, or by tickets already paid for, is a disorderly house—the test being whether the thing is done for gain. In some respects English Sunday laws are more explicit than those of Scotland. Special licensing laws regulate hotels and public-houses. There are also laws against killing game, using dogs on nets for sporting purposes, or fishing for salmon otherwise than with rod or line; the Factory Acts and Pawnbroking Acts exclude Sunday labour (Jews being excepted). Local regulations deal with theatres, museums, galleries, &c.

In Scotland a law of 1579 prohibits hand-labouring, working, gaming and playing; there was another act in 1661. And these statutes, often confirmed, have recently been held to be still valid. In some respects the law of Scotland is stricter; all salmon-fishing is forbidden. But in the main the legislation is the same. Diligence cannot be executed on Sunday, save in case of persons *in meditatione fuge*; contracts signed on that day are not necessarily void.

In America the law generally follows that of England, though some states have special regulations about Sunday travelling. There are rules in force for preserving order and quiet on that day; by municipal regulations or general statute places of amusement and houses for the sale of intoxicants are usually kept shut.

In sharp opposition to the bulk of Puritan testimony is the contention of the devout people formerly known as 'Sabbatarians,' still represented by the Seventh-day Baptists, and a section of the Tunkers. The English Sabbatarians of the 17th

century (represented by Theophilus Brabourne) strenuously contended that the Sabbath was divinely instituted at the close of the work of creation, and remains binding on all mankind till the end of the world; the seventh day of the week alone is the Scriptural Sabbath; as there is absolutely no warrant in Scripture for changing from the seventh day of the week to the first, this change is mere will-worship, and a most unjustifiable encroachment of man's imagination on God's law. From the time of the Apostles, they hold, there never wanted down to the Reformation sincere Christians who, in the face of obloquy and persecution, continued to observe the fourth commandment. In the Abyssinian Church the Sabbath has not been supplanted by Sunday, both days being kept; support is also claimed from the practice of the Armenians and Nestorians. Immediately after the Protestant Reformation were founded small societies testifying to the truth. The Seventh-day Adventists hold to the Sabbath.

Sabbioncello, or PELJEŠAC, a peninsula of Dalmatia, 43 miles long by about 4 wide, extends WNW. between the islands of Curzola and Lesina from a point about 25 miles WNW. of Ragusa. It reaches a height of some 3000 feet.

Sabellianism, a heresy about the distinction of Persons in God, the name of which is due to Sabellius, of whom but little is known, save that he was probably a native of Libya, came to Rome under Zephyrinus (A.D. 202-218), and was banished by Callistus, whereupon he took refuge in the Libyan Pentapolis. The Adoptionists and Modalists up to this time were the chief divisions of the Monarchians, the former making Christ the chosen of God, his divinity the effect of a complete oneness of will with him, the latter making him merely a manifestation of God. Modalism prevailed in Rome under the patronage of Callistus, but was denounced by Hippolytus, who was himself accused of *ditheism*. Sabellius held the more extreme Modalists, and offered strong opposition to Callistus, but his influence was far more important in the East than in the West, where the phrase of Athanasius that the Son and the Father are one and the same in substance (*ὁμοούσιος*) was at once accepted, though rejected at Antioch in 268.

The earlier form of Sabellianism was almost identical with Patripassianism, the chief teachers of which were Praxeas, Noctus, Epigonus, and Cleomenes. But it developed into a complete resolution of the Trinity into a mere threefold manifestation of God to man. Father, Son, and Holy Spirit are not distinct subsistences (*hypostases*), but merely one and the same person in different aspects, just as the sun is at once a spherical body, a fountain of light, and a source of heat. The single absolute Divine Essence—the *monas* or pure Deity—unfolds itself in creation and the history of man as a Trinity. The *energy* by which God called into being and sustains the universe is the *Logos*, after whose image men were created; but when they had fallen from perfection it became necessary for the *Logos*, or Divine Energy, to hypostatise itself in a human body, in order to raise and redeem them; hence in the man Christ Jesus dwelt the fullness of the Godhead *bodily*; while the same Divine Energy, operating spiritually and impersonally in the hearts of believers, is the Holy Ghost. Sabellius held further that these Divine manifestations are merely temporary, and that after the *Logos* and the Holy Ghost had done their work they would be reabsorbed in the absolute Deity—the *trias* would again resolve itself into the *monas*; or, in the language of St Paul, that 'God would be all in all.' Epiphanius alleges that Sabellius derived his system from an

apocryphal Gospel to the Egyptians; and there are, as Neander points out, so many points of resemblance in Sabellianism to the Alexandrian Jewish theology in general that the statement may be regarded as at least indicating the direction from which proceeded the influences that determined the theosophy of the unknown Pentapolitan. The 4th-century heresy associated with the name of Marcellus of Ancyra was closely allied to Sabellianism, which indeed becomes a term employed somewhat loosely. The followers of Sabellius were formally suppressed by the Catholic Church in the 4th century; but his doctrine, which, divested of its Gnostic and Neoplatonic phraseology about *emanation* and *re-absorption*, &c., is substantially Unitarian, has seldom wanted eminent advocates in any subsequent age of Christianity.

See the Church History of Neander; discussions by Schleiermacher and Lange; Döllinger's *Hippolytus u. Kallistus* (1853; Eng. trans. by Plummer, 1876); and Zahn's *Marcell. v. Ancyra* (1867).

Sabellians. See SABINES, SAMNITES.

Sabians. See SABAËANS, MANDEËANS.

Sabine, a river of Texas, rises near the northern boundary of Texas, and flows south east to the border of Louisiana, and then south, forming the boundary between the two states. It empties through Sabine Lake (18 miles long by 9 miles wide) into the Gulf of Mexico. The Sabine is 500 miles long, and though shallow is mostly navigable for small steamboats.

Sabine or SAVINE. See JUNIPER.

Sabine, SIR EDWARD, physicist, was born in Dublin, on the 14th October 1788. He obtained a commission in the artillery in his sixteenth year, and accompanied Ross and Parry as astronomer in the expeditions of 1818-20 in search of a north-west passage. Between 1821 and 1827 he undertook a series of voyages to places between the equator and the north pole, making at each point pendulum and magnetic experiments of great value. Elected a Fellow of the Royal Society in 1818, he was from 1861 to 1879 its president. He was for many years secretary of the British Association, and filled the office of president in 1853. In 1856 he was raised to the rank of major-general, in 1869 he was created K.C.B., retiring as general in 1877; and in 1875 he was elected a corresponding member of the French Academy. He died at Richmond, 26th June 1883, aged ninety-five. His scientific reputation rests chiefly upon his labours in terrestrial magnetism, his various memoirs in the *Philosophical Transactions* and Reports to the British Association being to this day invaluable collections of magnetic facts. By his personal influence he did more than any other single man in inducing the government to establish magnetic observatories in different parts of the world, and in initiating the valuable magnetic work now carried out by the Admiralty.

Sabines, an ancient Italian people whose original headquarters were amongst the central Apennines, but ultimately occupying an area which extended to their western slopes, and even to Rome itself. The Sabine territory, in the narrower sense, was bounded by that of the *Æqui*, *Piceni*, and *Umbrians* (see map of Italia Antiqua). They and their near kinsmen, the Samnites, constituted a group sometimes called *Sabellian*; and the two or more Sabellian peoples, together with the (less nearly) related Umbrians, spoke Italic dialects, to which the name of Umbro-Sabellian has been given. According to the legend, a colony of Sabines occupied the Quirinal Hill in Rome, but were ultimately incorporated with the Latin followers of Romulus upon the Palatine, and

so helped to constitute the Roman people (see **ROME**). The *Rape of the Sabines* belongs to this period of legendary history. Romulus, having difficulty in finding wives for his followers (credited with a dubious reputation as runaways and male-factors), invited the Sabines to a feast and games; and while the games were going on the garrison of the Palatine seized the unsuspecting and unprotected Sabine women, whom they carried off to be their wives. After several wars the Sabine country was ultimately annexed by Rome (290 B.C.).

Sable (*Martes zibellina*), a species of Marten (q.v.), so nearly allied to the Common Marten and Pine Marten that it is difficult to state satisfactory specific distinctions. The feet are covered with fur, even on the soles, and the tail is perhaps more bushy than in the British martens. The

Sable (*Martes zibellina*).

length, exclusive of the tail, is about 18 inches. The fur is brown, grayish yellow on the throat, and small grayish-yellow spots are scattered on the sides of the neck. The whole fur is extremely lustrous, and hence of the very highest value. The fur attains its highest perfection in the beginning of winter, and the pursuit of the sable at that season is one of the most difficult and adventurous of enterprises (see **FURS**). The sable is a native of Siberia, widely distributed over that country, and found in its coldest regions, at least wherever forests extend. The progress of geographical discovery in the eastern parts of Siberia has been much indebted to the expeditions of the hardy and daring sable hunters, exploring new regions at the worst season of the year, and spending dreary months at a great distance from all human abodes. The sable is taken by traps, which are a kind of pitfall, it being necessary to avoid injury to the fur; or by tracking it through the snow to its hole, and placing a net over the mouth of the hole. It is a very wary animal, and not easily captured. It makes its nest in a hollow tree, or sometimes, it is said, by burrowing in the ground, and lines it with moss, leaves, and grass. From this it issues to prey on hares and smaller animals of almost any kind, its agility enabling it even to catch birds among the branches of trees. It is ready, when food is scarce, to eat the remains of an animal on which a larger beast of prey has feasted, and is said even to satisfy its hunger with berries in winter, when animal food is not to be had. The sable, although it inhabits high northern latitudes, does not, as so many arctic animals do, change to white in the winter. This is accounted for by its habit of hunting among the branches of trees, against the dark colour of which white would be conspicuous, and therefore disadvantageous.

Sable Antelope (*Hippotragus niger*), a large South and East African antelope, with great formidable horns and heavy mane. It takes its name

from the glossy black of the male, contrasting with the white underparts.

Sable Island, a low-lying island in the Atlantic, in 44° N. lat. and 60° W. long, 110 miles E. of the central part of Nova Scotia (and not near Cape Sable, at the south-east corner of Nova Scotia, where there is also a Sable Island). It consists of two parallel sand ridges, with a lagoon between them. Scrubby grass and wild pease grow on the island, which is so dangerous to navigation, and has so frequently been the scene of wrecks, as to be called the 'sailor's grave.' There are two light-houses, one at each end of the island, with various life-saving appliances. In 1901 the Canadian government planted over 80,000 trees, to check the shifting of the sands. Near it there are sandbanks.

Sables D'Olonne, LES, a seaport of France (dept. Vendée), on the Atlantic coast, 50 miles S. by W. of Nantes, owes its early importance to Louis XI., who excavated (1472) the port and erected the fortifications. There is a trade in grain, wine, salt, cattle, timber, and tar. Salt-making, ship-building, and fishing (sardines and oysters) are the chief occupations. The town is visited for its sea-bathing. Pop. 13,000.

Sabots, a species of wooden shoes made out of one block, and largely used by the French and Belgian peasantry, especially by those who inhabit moist and marshy districts. They are made of fir, birch, beech, alder, walnut, and other wood, and are manufactured principally in the Cevennes districts of France, the more ornamental varieties especially at Mende, Villefort, and Marvejols, all in the department of Lozère. For greater comfort and convenience, straw is stuffed between the foot and the wooden sides, or, with the most luxurious, a low woollen sock, made to fit the hollow of the shoe. The name is sometimes extended to a kind of Clogs (q.v.) with wooden soles and leather uppers.

Sabre. See **SWORD**.

Sabrina Land, believed to have been discovered in the Antarctic (at 100° E. long.) by Bullen in 1839, was proved non-existent in 1911-13. *Sabrina* is the Latin form of *Severn*.

Sacac. See **SCYTHIANS**.

Saccharic Acid, $\text{H}_2\text{C}_6\text{H}_8\text{O}_6$, is a product of the action of nitric acid, under certain conditions, on grape and cane sugar, or on starch, gum, and lignine. It occurs as a colorless, inodorous, deliquescent, gummy, uncrystallisable mass, which is freely soluble in alcohol. It is sufficiently powerful to dissolve iron and zinc, with extrication of hydrogen. It has a tendency to form double salts. It is dibasic, and forms an acid and a normal salt with potassium.

Saccharimeter, or **SACCHAROMETER**, an instrument for determining the quantity of sugar in liquids, especially brewers' and distillers' worts. In principle it resembles the hydrometer (see **SPECIFIC DENSITY**), used for ascertaining the strength of alcoholic liquids. It consists of a hollow sphere or oval of thin brass, with a graduated stem and a hook so placed opposite each other that when placed in water it floats, and the graduated stem stands upright on the top, and the hook is below, for the purpose of appending weights. The degree to which the stem sinks gives the means of calculating, by tables prepared on purpose, the proportion of saccharine matter present in the liquid. See also **POLARISATION**, **SUGAR**.

Saccharin, or **GLUCIDE**, $\text{C}_6\text{H}_7\text{COSO}_2\text{NH}_2$, is a sweet substance prepared by complex processes from coal-tar. It is a white semi-crystalline powder, with a faint odour and intensely sweet

taste. So sweet is it that it requires to be very much diluted before its sweetness can be appreciated. Saccharin is but slightly soluble in water, but dissolves readily if mixed with baking-soda, carbonic acid gas being liberated during solution.

Saccharissa. See WALLER.

Saccharomycetes, or YEAST FUNGI, an order of Fungi including Saccharomyces and other genera which produce fermentation in sugar solutions, yielding alcohol and carbon dioxide. The process of budding is described at FERMENTATION (*Alcoholic Fermentation*). Asci may also be found. See FUNGI (and fig. 2a); also BEER, BREAD, SUGAR, WINE.

Saccharum. See SUGAR-CANE.

Sacchetti, FRANCO (c. 1330-99), an Italian novelist, a follower of Boccaccio, was a native of Florence, who held several diplomatic offices. Of his 258 *Novelle*, first printed in 1724, ten are translated in Thomas Roscoe's *Italian Novelists* (1825).

Saccolabium, an Indo-Malayan genus of epiphytic orchids much valued by cultivators.

Saccopharynx. See PELICAN-FISH.

Sacheverell, HENRY, D.D., was born in 1672 at Marlborough, the son of the High Church rector of St Peter's, and from the grammar-school there was sent by charity in 1689 to Magdalen College, Oxford. He shared rooms with Addison, who dedicated to his 'dearest Henry' *An Account of the Greatest English Poets* (1694); and, gaining successively a demyship and a fellowship, he took the degrees of B.A. (1693), M.A. (1696), B.D. (1707), and D.D. (1708). He had held the small Staffordshire vicarage of Cannock, when in 1705 he became preacher of St Saviour's, Southwark, and soon made his mark as a pulpit orator. In 1709 he delivered the two sermons—one at Derby assizes, the other on the 5th of November at St Paul's—which have given him a place in history. The rancour with which he assailed the principles of the Revolution Settlement and the Act of Toleration, whilst glancing at Godolphin as 'Volpone,' and asserting the doctrine of non-resistance, roused the wrath of the Whig government of the hour, and led to his impeachment before the House of Lords of high crimes and misdemeanours (1710). Ardent crowds, shouting 'High Church and Sacheverell!' and now and then wrecking a meeting-house, attended him to Westminster; he defended himself ably (Burnet ascribes the defence to Atterbury), but by a majority of seventeen he was found guilty, and suspended for three years from preaching, his two sermons also being burned by the common hangman. The ministry fell that same summer, and in 1713, on the expiry of his suspension, Sacheverell was selected by the House of Commons to preach the Restoration sermon before them, and specially thanked on the occasion. A more substantial token of favour was his presentation to the rectory of St Andrew's, Holborn, after which little more is heard of him save that he squabbled with his parishioners, and was suspected of complicity in a Jacobite plot. He died at the Grove, Highgate, 5th June 1724, and was buried in St Andrew's, Holborn, whence his lead coffin was stolen in 1747.

See the Bibliography by Madan in the *Bibliographer* for 1883-84, and the histories of Queen Anne's reign by Hill Burton, Lord Stanhope, Herbert Paul (1906), and others.

Sachs, HANS, the most prolific and at the same time the most important German poet of his time, was born on 5th November 1494, at Nürnberg, where his father was a tailor. While at school he learned the rudiments of Latin, but was never a scholar in the academic sense of the term, although he was a very well and widely informed man.

About the age of fifteen he began to learn the craft of shoemaking; his love of verse also led him to learn the art, almost mechanical, of verse-making from Leonhard Nunnenbeck, a weaver and *meistersinger* in his native town. On finishing his apprenticeship, Sachs, as was the custom of craftsmen in those days, made a tour through Germany, practising his calling in various cities, and frequenting assiduously the schools or corporations organised by the *meistersinger*, who, since the disappearance of the older *minnesinger*, or minstrels of chivalry, had become the chief representatives of German poetry. On his return to Nürnberg in 1516, Sachs set up as a shoemaker, and prospered; and, after a long, cheerful, and happy life, died on 19th (or 25th) January 1576.

Sachs's career as an author is divided into two periods. In the first he shows an interest mainly in the occurrences that were then agitating Germany. It was the epoch of the Reformation of Luther, whose praises he celebrated (1523) in an allegorical tale entitled *Die Wittenbergisch Nachtigal*, while his poetical fly-sheets (of which about 200 are known) furthered in no small measure the Protestant cause. In the second period his poetical activity was turned more to the delineation of common life and manners. His poetry is distinguished by its heartiness, good sense, homely morality, and fresh humour. It is, however, deficient in high imagination and brilliant fancy, and contains much prosaic and insipid verse. It was his chief pride to be an honourable citizen of Nuremberg, and his mind and his interest seldom travel beyond the narrow limits of its encircling walls. There is not one of his productions but what was meant to serve some didactic purpose. His best works are *Schwauke*, or Merry Tales, the humour of which is sometimes unsurpassable, serious tales, allegorical and spiritual songs, and Lenten dramas. His *meistersinger* pieces he wrote according to the precepts of the verse makers' guild, are now of little or no value, though in his own day they raised him to the first place amongst all his contemporaries. By the 52d year (1567) of his career as a poet he had written 34 vols., containing upwards of 6300 pieces, among which were more than 4000 *meistersinger*, 200 comedies and tragedies, about 1700 merry tales, secular and religious dialogues, proverbs, and fables, 7 prose dialogues, and 70 songs, secular and devotional. The first edition of his works was published at Augsburg in 1558-61, but that of Willer (5 vols. 1570-79) is better. After the middle of the 17th century Hans Sachs fell into neglect and was forgotten; and he remained so until his memory was revived by Goethe in 1776. His complete works were published by Götz and Von Keller (Stuttg. 26 vols. 1870-1908). The selections of Merry Tales and Proverbs in Verse by Goedeke and Tittmann (3 vols. 1883-85) and by Engelbrecht (1879) can be recommended, as well as Tittmann's edition of the Lenten Dramas.

Sachs, JULIUS VON, botanist, born at Breslau, 2d October 1832, studied at Prague and began to teach botany there. After lecturing at the forestry academy of Tharandt in Saxony and at the agricultural college of Poppelsdorf near Bonn from 1859 to 1867, he was in the last year appointed professor of Botany at Freiburg, but removed to Würzburg in the following year. There he carried on, in a laboratory built under his own direction, important experiments in plant physiology, especially in determining the influence of light and heat upon plants, and in investigating the movements and other organic activities of vegetable growth. He died 25th May 1897. His works include *Lehrbuch der Botanik* (4th ed. 1874; Eng. trans.

1875), *Handbuch der Experimental-physiologie der Pflanzen* (1866), *Geschichte der Botanik vom 16. Jahrhundert bis 1860* (1875; Eng. trans. 1890), of which Reynolds Green's *History of Botany 1860-1900* (1909) is a continuation, *Grundzüge der Pflanzenphysiologie* (1873), and *Vorlesungen über Pflanzenphysiologie* (Eng. trans. 1887).

Sack, a name in common use in the time of Shakespeare, and occurring down to the middle of the 18th century as denoting a kind of wine. The exact nature of this famous wine, the favourite beverage of Falstaff, and the origin of the name have been much discussed. Sack or seck seems to be simply an English disguise of the Spanish *seco* (Fr. *sec*), applied to wines of the sherry genus, as distinguished from the sweet wines; a term which we now translate by 'dry.' Canary was often the wine meant by sack. In old churchwardens' accounts sack is frequently mentioned as a communion wine. It seems to have been mixed with port; and this mixture of white and red wines survived at Douglas in the Isle of Man till at least 1887 (*Notes and Queries*, 1887-88).

Sackbut (Fr. *sacquebute*), a kind of trumpet, the predecessor of the Trombone (q.v.). The word was used at random by the translators of the Bible.

Sackville, CHARLES, sixth Earl of Dorset, was born 24th January 1637, and succeeded to the title in 1677. He travelled in Italy, was returned by East Grinstead to the first parliament of Charles II., and soon became an especial favourite of the king, and notorious, like too many of the courtiers, for his boisterous and indecorous frolics. He served under the Duke of York at sea, was employed on various missions, but could not endure the tyranny of James II., and was one of the most ardent in the cause of the Prince of Orange. His later years were honoured by a generous patronage of men of letters like Prior, Wycherley, and Dryden. He died at Bath, 19th January 1706. He was himself the author of a few occasional lyrical and satirical pieces, but is only remembered for one short poem, the bright and delightful song, 'To all you Ladies now on Land.'

Sackville, THOMAS, Earl of Dorset, poet and statesman, was born about 1536 at Buckhurst in

Sussex, the only son of Sir Richard Sackville, Chancellor of the Exchequer. He is supposed to have studied at Hart Hall, Oxford, and St John's College, Cambridge, and then to have entered the Inner Temple; in 1554 he married, and in 1558 was returned to parliament. With Thomas Norton he produced the blank-verse tragedy of *Ferrex and Porrex* (afterwards called *Gorboduc*), which in January 1562 was acted before Queen Elizabeth (Sackville's second-cousin) at Whitehall by the gentlemen of the Inner Temple. This work, whose plot is founded on a British legend, and which is after the style of Seneca, the incidents being moralised at intervals by a chorus, claims particular notice as the earliest tragedy in the English language. Dramatic energy it has none, but the style is pure and stately, evincing eloquence and power of thought (see DRAMA). Sackville's other chief production was the *Induction to a Myrrour for Magistrates* (1563), a noble poem, 'uniting,' as Hallam says, 'the school of Chaucer and Lydgate to the *Faery Queen*,' and almost rivalling the latter in the magnificence and dignity of its allegoric personifications—and the legend of *Buckingham* for the same work. The influence of Dante is very perceptible. His prodigality brought Sackville into disgrace with the queen, and he travelled awhile in France and Italy, but on his father's death in 1566 returned to England, and next year was knighted and created Lord Buckhurst. He was now employed much as a diplomatist in France and the Low Countries; in 1586 announced her death-sentence to Mary, Queen of Scots; in 1589 was installed a Knight of the Garter; in 1599 succeeded Burghley as lord high treasurer; and in 1604 was created Earl of Dorset. He died suddenly at Whitehall at the council table, 19th April 1608.

See the Life prefixed to his Works by Sackville-West (1859); Cunliffe in *Cambridge History of English Literature*, vol. iii.; and W. F. Trench's edition of *A Mirror for Magistrates* (1898).

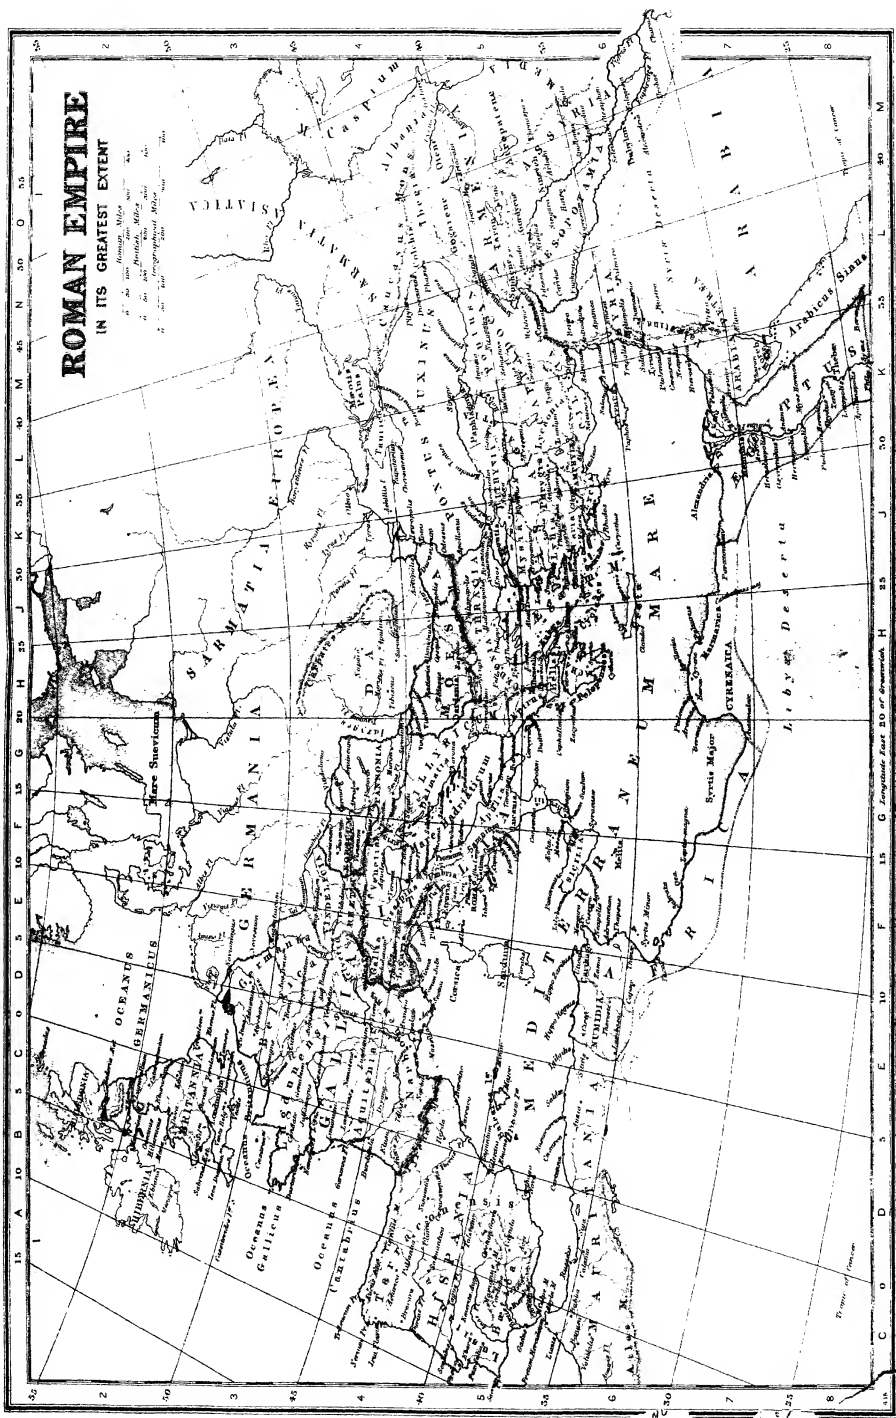

Saco, a city and port of entry of Maine, on the left bank of the Saco River, here crossed by a bridge to Biddeford, and with falls of 50 feet supplying water-power, 16 miles by rail WSW. of Portland. It contains cotton and shoe factories, saw-mills, machine-shops, &c. Pop. 7000.—The *Saco River* rises in the White Mountains of New Hampshire, and runs south-east through Maine to the Atlantic. It is 170 miles long.
